Both these are propagated by parting of their roots; the best time for this is in autumn: they should be planted in a shady situation, and they love a soft loamy soil.

MITELLA MAXIMA. See BIXA.

MOLDAVICA. See DRACOCEPHALUM.

MOLLE. See SCHINUS.

MOLLUGO. Lin. Gen. Plant. 99.

The CHARACTERS are,

The empalement of the flower is composed of five oblong small leaves, which are coloured on their inside, and is permanent. The flower has five oval petals, which are shorter than the empalement, and three bristly stamina, which stand near the style, and are terminated by single summits, with an oval germen having three furrows, supporting three very short styles, crowned by obtuse stigmas. The germen afterward becomes an oval capsule with three cells, filled with small kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's third class, which includes those plants whose flowers have three stamina and three styles.

The SPECIES are,

1. MOLLUGO (*Verticillata*) foliis verticillatis cuneiformibus acutis, caule subdiviso decumbente, pedunculis unifloris. Hort. Upsal. 24. *Mollugo with acute wedge-shaped leaves, growing in whorls, a trailing divided stalk, and foot-stalks bearing a single flower. Alfine procumbens, galii facie Africana. Hort. Lugd. Trailing African Chickweed, with the appearance of Ladies Bedstraw.*
2. MOLLUGO (*Quadrifolia*) foliis quaternis obovatis, paniculâ dichotomâ. Hort. Cliff. 28. *Moluggo with four leaves at each joint, which are almost oval, and a panicle arising at the division of the branches. Herniaria alfine folio. Tourn. Inst. 507. Rupturewort with a Mouse Ear leaf.*

There are two or three species of this genus, which are rarely admitted into gardens, so I have not enumerated them here.

Both these sorts are annual; the first is a native of warm countries, so is less hardy than the second; they are both trailing plants, whose stalks lie flat on the ground; the first spreads out eight or nine inches every way; and at each joint is garnished with six or seven small leaves spread out in form of a star. The flowers are small, like those of Chickweed, one standing upon each foot-stalk; these are succeeded by oval capsules filled with small seeds, which, if permitted to scatter, the plants will come up the following spring without any care; but when the seeds happen to fall upon earth which is thrown upon a hot-bed, the plants will be forwarder and stronger than those in the open air. This is preserved in some gardens for the sake of variety, but has no great beauty.

M O L

MOLUCCELLA. Lin. Gen. Plant. 643. Molucca. Tourn. Inst. R. H. 187. tab. 88. [This plant takes its name from the Molucca Islands, because it was found there.] Molucca Balin.

The CHARACTERS are,

The flower hath a large permanent empalement of one leaf, which is deeply indented at the brim, where it spreads open. The flower is of the lip kind, with a short tube and chaps. The upper lip is erect, concave, and entire. The under lip is trifid, the middle segment being longer than the other. It has four stamina situated under the upper lip, two of which are shorter than the other, crowned by single summits, and a germen with four parts, supporting a style situated with the stamina, crowned by a bifid stigma. The germen afterward turns to four angular convex seeds, sitting in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, which includes those plants whose flowers have two long and two short stamina, and are succeeded by naked seeds in the empalement.

The SPECIES are,

1. MOLUCCELLA (*Lævis*) calycibus campaniformibus subquinqüedentatis, denticulis æqualibus. Lin. Sp. 821. *Molucca Balin with bell-shaped empalements, indented in five equal parts. Molucca lævis. Dod. Pempt. 92. Smooth Molucca Balin.*
2. MOLUCCELLA (*Spinosa*) calycibus ringentibus octodentatis. Lin. Sp. 821. *Molucca Balin whose empalements are ringent, indented in eight parts. Molucca spinosa. Dod. Pempt. 92. Prickly Molucca Balin.*

The first sort rises with a square stalk three feet high, spreading out into many branches, which are smooth, and come out by pairs, garnished with roundish leaves, which are deeply notched on their edges, standing upon long foot-stalks placed opposite; they are smooth, of a light green on both sides, and at the base of their foot-stalks the flowers come out in whorls; these have very large spreading empalements, which are indented in five parts, and immediately under them come out two bunches of pretty long spines, one on each side the stalk, each bunch consisting of five or six spines arising from the same point. The flowers are small, and being situated at the bottom of the large empalements, are not visible at a distance; they are white, with a cast of purple, and shaped like those of the other lip flowers, having the upper lip entire, and hollowed like a spoon, and the under lip is cut into three segments, the middle one being the longest. After the flower is past, the germen turn to four club-shaped angular seeds inclosed in the empalement. It flowers in July, but unless the season proves warm and dry, the seeds do not ripen in England. The smell of this plant is to some persons very disagreeable, and to others very pleasant.

The second sort hath square smooth stalks, of a purplish colour, which rise four feet high, and branch out in the same manner. The leaves are smaller, and stand upon shorter foot-stalks; they are deeper, and more acutely indented on their edges. The empalements of the flowers are not so large, and are cut into eight segments, each being terminated by an acute spine. The flowers are like those of the former species, as are also the seeds; this is not so hardy as the first sort.

The first grows naturally in several parts of Syria, and the second is a native of the Molucca Islands, from whence this genus received its title. They are both annual plants, which decay soon after their seeds are ripe, and being natives of warm countries, they seldom perfect their seeds in England, when they are sown in the spring; therefore the best way is to raise the plants in autumn, and plant them in small pots; these should be placed under a hot-bed frame in winter, where they may have free air in mild weather, by taking off the glasses, but covered in frosty weather, observing to keep them pretty dry, otherwise they are very subject to rot, when they are closely covered in frosty weather. In the spring the plants may be turned out of the pots, with all the earth about their roots, and planted in a warm border, defended from

from strong winds, giving them a little water to settle the earth to their roots; after this they will require no other care but to keep them clean from weeds, and to support them with stakes, to prevent their being broken by the winds. The plants thus preserved through the winter, will flower the latter end of June, so from these good seeds may be expected.

MOLY. See ALLIUM.

MOMORDICA. Tourn. Inst. R. H. 103. tab. 29, 30. Lin. Gen. Plant. 1090. Male Balsam Apple; in French, *Pomme de Marveille*.

The CHARACTERS are,

It hath male and female flowers upon the same plant. The male flowers have a spreading empalement of one leaf. The flower hath one petal, which adheres to the empalement. It has three short awl-shaped stamina; in two of the stamina the summits are bifid, and eared on both sides; the third has a single eared summit; these are compressed in a body. The female flowers have the same empalement and petal as the male, but sit upon the germen; these have three short filaments without summits. The germen supports one taper trifid style, crowned by three oblong gibbous stigmas. The germen afterward turns to an oblong fruit, opening with an elasticity, having three membranaceous cells, filled with compressed seeds.

This genus of plants is ranged in the tenth section of Linnæus's twenty-first class, which contains the plants with male and female flowers on the same plant, whose stamina coalesce together.

The SPECIES are,

1. MOMORDICA (*Balsamina*) pomis angulatis tuberculatis, foliis glabris patentipalmatis. Hort. Cliff. 451. *Male Balsam Apple with angular warted fruit, and smooth open-banded leaves.* Momordica vulgaris. Tourn. Inst. R. H. 103. *Common male Balsam Apple.*
2. MOMORDICA (*Charantia*) pomis angulatis tuberculatis, foliis villosis, longitudinaliter palmatis. Hort. Cliff. 451. *Male Balsam Apple with angular warted fruit, and hairy leaves, which are longitudinally hand-shaped.* Momordica Zeylanica, pampinea fronde, fructu longiori. Tourn. Inst. R. H. 103. *Male Balsam Apple of Ceylon, with a Vine leaf and a longer fruit.*
3. MOMORDICA (*Zeylanica*) pomis ovatis acuminatis tuberculatis, foliis glabris palmatis ferratis. *Male Balsam Apple with an oval, acute-pointed, warted fruit, and smooth hand-shaped leaves, which are sawed.* Momordica Zeylanica, pampinea fronde, fructu breviori. Tourn. Inst. 103. *Male Balsam Apple of Ceylon, with a Vine leaf and a shorter fruit.*
4. MOMORDICA (*Elaterium*) pomis hispidis, cirrhis nullis. Lin. Sp. Plant. 1010. *Male Balsam Apple with a prickly fruit, and no tendrils to the Vines.* Cucumis sylvestris aspinus dictus. C. B. P. 314. *Wild Cucumber, called Asses Cucumber, and the Elaterium of Boerhaave.*

The first sort grows naturally in Asia, the second and third in the island of Ceylon; they are annual plants, which perish soon after they have ripened their fruit; these have trailing stalks like those of the Cucumber and Melon, which extend three or four feet in length, sending out many side branches which have tendrils, by which they fasten themselves to any neighbouring plants, to secure themselves from being tossed and blown about by the winds, and are garnished with leaves shaped like those of the Vine. The leaves of the first and third sorts are smooth, and deeply cut into several segments, and spread open like a hand; but those of the second sort are extended more in length, and are hairy. The fruit of the first species is oval, ending in acute points, having several deep angles, which have sharp tubercles placed on their edges; it changes to a red or purplish colour when ripe, opening with an elasticity, and throwing out its seeds.

The fruit of the second sort is much longer than that of the first, and not so deeply channelled. The tubercles are scattered all over the surface, and are not sharp like those of the other; this fruit is yellow,

when ripe, and casts out its seeds with an elasticity.

The fruit of the third sort is short and pointed like that of the first, but does not swell so large in the middle. The angles of this are not deep, and the whole surface is closely set with sharp tubercles; this changes to a deep Orange colour when ripe, and casts out its seeds in the like manner.

The fourth sort is commonly called Wild or Spurring Cucumber, from its casting out its seeds, together with the viscid juice in which the seeds are lodged, with a violent force, if touched when ripe; and from hence it has sometimes the appellation of *Noli me tangere*, or *touch me not*. This plant grows naturally in some of the warm parts of Europe, but in England it is cultivated in gardens for the fruit, which is used in medicine, or rather the fæcula of the juice of the fruit, which is the Elaterium of the shops.

This plant hath a large fleshy root somewhat like that of Briony, from which come forth every spring several thick, rough, trailing stalks, which divide into many branches, and extend every way two or three feet; these are garnished with thick, rough, almost heart-shaped leaves, of a gray colour, standing upon long foot-stalks. The flowers come out from the wings of the stalk, these are male and female, growing at different places on the same plant, like those of the common Cucumber, but they are much less, of a pale yellow colour, with a greenish bottom: the male flowers stand on short thick foot-stalks, but the female flowers sit upon the young fruit, which, after the flower is faded, grows to be an inch and a half long, and swelling like a Cucumber, of a gray colour like the leaves, and covered over with short prickles. These do not change their colour when ripe, like most of the other fruit of this class; but if attempted to be gathered, they quit the foot-stalk, and cast out the seeds and juice with great violence; so that where any plants are growing, and the fruit permitted to stand till it is ripe, the seeds will be scattered all round to a great distance, and there will be plenty of the plants produced the following spring.

But when the fruit is designed for use, it should always be gathered before it is ripe, otherwise the greatest part of the juice will be lost, which is the only valuable part; for the juice which is expressed, with part of the parenchyma of the fruit, is not to be compared with the other for its virtues; for the Elaterium which is made from clear juice of the fruit, is much whiter, and will retain its virtues much longer, than that which is extracted by pressure.

The three first sorts are annual; their seeds must be sown on a hot-bed the beginning of March, and when the plants come up, they should be transplanted out into a fresh hot-bed, after the manner of Cucumbers or Melons, putting two plants of the same kind under each light, and the plants watered and shaded until they have taken root; after which they must be treated as Cucumbers, permitting their branches to extend upon the ground in the same manner, and observe to keep them clear from weeds.

With this management (provided you do not let them have too much wet, or expose them too much to the open air) they will produce their fruit in July, and their seeds will ripen in August and September, when you must observe to gather it as soon as you see the fruit open, otherwise it will be cast abroad, and with difficulty gathered up again.

These plants are preserved in curious gardens for the oddness of their fruit; but as they take up a great deal of room in the hot-beds, requiring frequent attendance, and being of little beauty or use, so they are not much cultivated in England, except in botanic gardens for variety.

There are some persons who put these plants in pots, and fasten them up to stakes, to support the Vines from trailing on the ground, and place the pots in stoves; where, when they are skilfully managed, they will

will produce their fruit tolerably well; and in this way they make a better appearance, than when the Vines spread on the ground like Cucumbers and Melons. But when the plants spread on the ground, which is their natural way of growing, they thrive much better, and produce more fruit, than when they are supported; for though these plants have clasps, yet these are not formed for climbing, but merely to fasten themselves about any neighbouring support, to secure them from being raised by the wind and broken; which would often happen, where they grow in the open air and are fully exposed, were it not for this security.

The fourth sort is easily propagated by seeds, which (as was before mentioned) if permitted to scatter, there will be a supply of plants come up the following spring; or if the seeds are sown upon a bed of light earth, the plants will come up in about a month after, and may be transplanted to an open spot of ground, in rows at three or four feet distance, and almost as far asunder in the rows; if these are carefully transplanted while young, there will be little hazard of their growing; and after they have taken new root, they will require no further care, but to keep them clear from weeds. If the ground is dry in which they are planted, the roots will continue three or four years, unless the winter should prove very severe, which will kill them.

MONARDA. Lin. Gen. Plant. 34. Leonurus. Tourn. Inst. R. H. 187. tab. 87.

The CHARACTERS are,

The flower has a tubulous cylindrical empalement of one leaf, which is channelled, and cut into five equal parts at the brim. The flower hath one petal, and is of the lip kind, having a cylindrical tube longer than the empalement, divided at the top into two lips. The upper lip is narrow, entire, and erect; the under lip is broad, trifid, and reflexed; the middle segment being long and narrow, those on the side are obtuse. It hath two bristly stamina the length of the upper lip, in which it is involved, terminated by compressed erect summits. In the bottom of the tube is situated a four-pointed germen, supporting a slender style involved with the stamina, and crowned by an acute bifid stigma. The germen afterward turns to four naked seeds, inclosed in the empalement.

This genus of plants is ranged in the first section of Linnaeus's second class, which includes the plants whose flowers have two stamina and one style.

The SPECIES are,

1. MONARDA (*Isifulosa*) capitulis terminalibus, caule obtus-angulo. Hort. Upsal. 12. *Monarda with heads of flowers terminating the stalks, which have obtuse angles.* Leonurus Canadensis, organi folio. Tourn. Inst. R. H. 187. *Canada Lion's Tail, with an Origanum leaf.*
2. MONARDA (*Didyma*) floribus capitatis, sub-didynamis, caule acutangulo. Lin. Sp. Plant. 32. *Monarda with headed flowers, whose stamina are almost in two bodies, and an acute angular stalk.* Monarda floribus capitatis verticillatisque, caule acutangulo, foliis lanceolato-ferratis glabris. Butt. Cun. 226. *Monarda with flowers collected in heads and whorls, an acute-angular stalk, and smooth, sawed, spear-shaped leaves, commonly called Oswego Tea.*
3. MONARDA (*Punctata*) floribus verticillatis, corollis punctatis. Hort. Upsal. 12. *Monarda with flowers growing in whorls, whose petals are spotted.* Clinopodium Virginianum, angustifolium, floribus amplis luteis, purpurâ maculâ notatis, cujus caulis sub quovis verticillo decem vel duodecim foliolis rubentibus est circumcinctis. Banist. Raii Sup. 300. *Narrow-leaved Field Basil of Virginia, with large yellow flowers spotted with purple, whose stalks have ten or twelve reddish leaves under each whorl of flowers.*

The first sort grows naturally in Canada, and many other parts of North America. It hath a perennial root, composed of many strong fibres, which spread far on every side. The stalks rise near three feet high, which are hairy, and have obtuse angles; these send out two or four small side branches toward the top,

garnished with oblong leaves, broad at their base, but terminate in acute points; they are hairy, a little indented on their edges, standing on short hairy foot-stalks, and are placed opposite. The stalk and branches are terminated by heads of purple flowers, which have a long involucre, composed of five acute-pointed leaves. The flowers have each two stamina which are longer than the petal, with a style of the same length, crowned by a bifid stigma. The flowers appear in July, and are succeeded by seeds which ripen in the autumn.

The second sort grows naturally in North America, where the inhabitants frequently use the leaves for tea, so it is commonly called Oswego Tea, by which title it was brought to England. This hath a perennial root and an annual stalk, which decays every autumn. The stalks of this sort are smooth, having four acute angles; they rise about two feet high, and are garnished with smooth, oval, spear-shaped leaves, which are indented on their edges, and stand opposite on very short foot-stalks; these when bruised, emit a very grateful refreshing odour; the stalks send out toward their top two or four small side branches, which are garnished with small leaves of the same shape with the other. The flowers are produced in large heads or whorls at the top of the stalk, and there is often a smaller whorl of flowers, growing round the stalk at a joint below the head; and out of the head arises a naked foot-stalk, sustaining a small head or whorl of flowers: the flowers are of a bright red colour; they have two lips, the upper lip is long, narrow, and entire, the under lip is cut into three parts; they have each two stamina which are longer than the petal, terminated by compressed summits, and many of them have two shorter stamina, without summits. The plant flowers in July, but in a moist season, or when the plants are in a moist soil, they will continue in flower till the middle or latter end of September.

Both these sorts may be propagated by parting of their roots; the first does not multiply so fast as the second, but as that produces plenty of seeds, so it may be easily propagated that way. If the seeds are sown in the autumn soon after they are ripe, the plants will come up the following spring; but if they are not sown till spring, the plants seldom rise till the next year. When the plants are come up and are fit to remove, they should be transplanted into a shady border about nine inches distance, and when they have taken new root, they will require no other care but to keep them clean from weeds till the autumn, when they should be transplanted into the borders where they are to remain. The following summer they will flower and produce ripe seeds, but the roots will continue several years, and may be parted every other year to increase them. This loves a soft loamy soil, and a situation not too much exposed to the sun.

The second sort seldom ripens seeds in England, but it increases fast enough by its creeping roots, as also by slips or cuttings, which, if planted in a shady border in May, will take root in the same manner as Mint or Balm; but as the roots multiply so fast, there is seldom occasion to use any other method to propagate them.

This sort loves a moist light soil, and in a situation where the plants have only the morning sun, they will continue longer in flower than those which are exposed to the full sun. This is a very ornamental plant in gardens, and the scent of the leaves is very refreshing and agreeable to most people, and some are very fond of the tea made with the young leaves.

The third sort grows naturally in North America; this is a biennial plant, and probably in its native country may be an annual, for the roots perish after the plants have perfected their seeds. This hath square stalks which rise about two feet high, branching out from the bottom to the top, and are garnished with spear-shaped leaves, which come out in clusters at each joint, where there are two larger leaves placed

placed opposite, and several smaller come out on each side the stalk; the larger leaves are about two inches and a half long, and three quarters of an inch broad, and are slightly indented on their edges. Toward the upper part of their stalk the flowers come out in large whorls, having to each whorl an involucre, composed of ten or twelve small spear-shaped leaves, of a purplish red colour on their upper side; the flowers are pretty large, of the same form with those of the other sorts, of a dirty yellow colour spotted with purple; they have each two long stamina situated under the upper lip, which are terminated by bifid compressed summits, and are succeeded by four naked seeds inclosed in the empalement. It flowers in July, and if the summer proves favourable, the seeds sometimes ripen in the autumn.

This plant is propagated by seeds, which, if sown on a border of light earth exposed to the east, the plants will rise very freely; when they are fit to remove, they may be transplanted into a shady border, in the same manner as hath been directed for the first sort; and if they should shoot up stalks to flower, they should be cut down to strengthen the roots, that they may put out lateral buds, for when they are permitted to flower the first year, the roots seldom live through the winter, therefore they should be prevented: in the autumn the plants may be removed, and planted in the open borders of the pleasure-garden, where they will flower the following summer; and if the season should prove dry, they should be duly watered, otherwise they will not be near so beautiful, nor will the plants produce good seeds.

MONBIN. See SPONDIAS.

MONTIA. See HELIOCARPUS.

MORÆA. Lin. Gen. Plant. 60.

The CHARACTERS are,

The sheath of the flower has two valves; the flower is composed of six petals, the three upper are erect and bifid, the three under spread open; it hath three short stamina, terminated by oblong summits. The germen is situated below the flower, supporting a single style, crowned by a trifid erect stigma. The germen afterward becomes a three-cornered capsule, having three furrows, with three cells, containing several round seeds.

This genus of plants is ranged in the first section of Linnæus's third class, intitled Triandria Monogynia, the flower having three stamina and one style.

The SPECIES are,

1. MORÆA (*Vegeta*) spatha uniflora, foliis gladiolatis. *Morea with one flower in each sheath, and sword-shaped leaves.* Moræa foliis canaliculatis. Lin. Sp. 59. *Morea with channelled leaves.*
2. MORÆA (*Funcea*) spatha biflora, foliis subulatis. *Morea with two flowers in each sheath, and awl-shaped leaves.* Moræa foliis subulatis. Lin. Sp. 59. *Morea with awl-shaped leaves.*

These plants are both natives of the Cape of Good Hope, from whence I received their seeds, which have succeeded in the Chelsea garden, where the plants have several times produced their flowers, which differing from all the other genera of plants in the same class, I have taken the liberty of titling it Morea, in honour of Robert More, Esq; of Shrewsbury, who is well skilled in the science of botany, and also in other parts of natural history.

The first sort has fibrous roots like those of the Flag-leaved Iris, from whence arises many small sword-shaped leaves, five or six inches long, and half an inch broad in the middle, diminishing toward both ends, of a deep green colour, lying over each other at their base, in the same manner as the Iris; the flower-stalk arises between the leaves from the root, about eight inches high, having one small leaf at each joint, and is terminated by one flower, which is covered with a spatha (or sheath) having two valves; the flower is of a dirty white, each petal having a blush of purple toward their upper part, and a pretty broad spot of yellow toward their tails; within are three slender stamina terminated by oblong summits, and one style crowned by a trifid stigma. The flow-

ers appear in June, and the seeds ripen the end of July.

The second sort hath a small bulbous root, a little compressed on the sides, with a smooth dark-coloured skin, from which arise three or four awl-shaped leaves of a pale green, some of which are five inches long, and others are seven or eight, and about half an inch broad, terminating with three angles; the foot-stalks of the flowers rise about six inches high, and generally bend at their lower joint; these are garnished with a small leaf at each joint, whose base almost surrounds the stalk, which is terminated by two flowers, encompassed with a withered sheath; the flowers are of an Orange colour; the petals are pretty broad upward, but are connected at their base. These appear in June, and the seeds ripen the end of July.

The plants are propagated either by seeds, or from offsets of the second sort, and by parting or dividing the roots of the first; the best time for transplanting of them, and separating the offsets of the second sort, and parting the roots of the first, is in August, that they may put out new fibres before winter; and that is also the right season for sowing of the seeds, for when they are sown at this time of the year in small pots, and plunged into a bed of old tanners bark, under a common frame in winter, there is little danger of these seeds miscarrying. The plants will also require this sort of shelter in winter, for as they are too tender to thrive in the open air in England, and if they are placed in a green-house, they are apt to draw up weak, therefore when they are sheltered under a frame, so as to enjoy the free open air in winter when the weather is warm, and secured from frost and hard rains, they will flower and ripen their seeds better than with any other management: in summer they should be fully exposed to the open air till October, when they should be removed into shelter.

MORINA. Tourn. Cor. 48. tab. 480. Lin. Gen. Plant. 39. Diotrothea. Vaill. Mem. Acad. 1722.

The CHARACTERS are,

It hath a double empalement; that under the fruit is tubulous, cylindrical, of one leaf, indented at the brim, and permanent; that of the flower is tubulous, bifid, of one leaf, and permanent. The flower hath one petal, with a long tube enlarged upward, and a little incurved. The top is divided into two lips; the upper lip is small and bifid, the under lip is cut into three equal obtuse segments, the middle one being extended beyond the other. It hath two bristly stamina situated near the style, terminated by heart-shaped erect summits. The globular germen is situated under the flower, supporting a slender style which is longer than the stamina, crowned by a target-shaped stigma; the germen afterward becomes a single seed, crowned by the empalement of the flower.

This genus of plants is ranged in the first section of Linnæus's second class, which contains those plants whose flowers have two stamina and one style.

There is but one SPECIES of this genus at present known, which is,

MORINA (*Orientalis*.) Hort. Cliff. 14. Morina Orientalis, carlinæ folio. Tourn. Cor. *Eastern Morina, with a Carline Thistle leaf.*

This plant was discovered by Dr. Tournefort, in his travels in the Levant, who gave it this name in honour of Dr. Morin, a physician at Paris.

It grows naturally near Erzeron in Persia, and was in the English gardens before the severe winter in 1740, which killed all the plants that were here, also those in the garden at Paris; so the only plant remaining was in the garden of Monsieur du Hamel. The root of this plant is taper and thick, running deep into the ground, sending out several thick strong fibres as large as a finger; the stalk rises near three feet high; it is smooth, of a purplish colour toward the bottom, but hairy and green at the top, garnished at each joint by three or four prickly leaves like those of the Carline Thistle; they are four or five inches long, and an inch and a half broad, of a lucid green on their upper side, but of a pale green on their under, and a little hairy, armed on their edges with spines. The flowers come

out from the wings of the leaves on each side the stalk; these have very long tubes, which are slender at the bottom, but are enlarged upward, and are a little incurved; the brim spreads open with two large lips, the upper lip is indented at the top and rounded, the lower lip is cut into three obtuse segments; under the lip are situated two bristly stamina which are crooked, and crowned with yellow summits. These flowers appear in July, but I never had any seeds succeed them. Some of the flowers are white, and others of a purplish red on the same plant.

This plant is propagated by seed, which should be sown soon after it is ripe in the autumn, otherwise the plants will not come up the following summer; for I have several times observed, where the seeds have been sown in the spring, they have remained in the ground fourteen or fifteen months before the plants have appeared. These seeds should be sown in the places where the plants are to remain, because they send forth tap-roots, which run very deep into the ground; and when these are broken or injured in transplanting, the plants seldom thrive after. They may be sown in open beds or borders of fresh light earth, being careful to mark the places, that the ground may not be disturbed; for it frequently happens, that the seeds do not come up the first year, when they are sown in autumn; but when they are sown in the spring, they never come up the same year. The ground where the seeds are sown must be kept clear from weeds, which is all that is necessary to be done, until the plants come up; where they are too close together, they should be thinned while young, so as to leave them near eighteen inches apart; after which time, they will require no other culture but to keep them constantly clear from weeds; and in the spring, just before the plants put out new leaves, to dig the ground gently between them, and lay a little fresh earth over the surface of the bed to encourage them.

In autumn these plants decay to the ground, and send forth new leaves the following spring, but it will be three years from the time of the plants first coming up to their flowering, though after that time they will flower every season; and the roots will continue many years, provided they are not disturbed, or killed by very severe frost.

MORUS. Tourn. Inst. R. H. 589. tab. 363. Lin. Gen. Plant. 936. [of μαυρός, black, because its fruit is ordinarily so.] The Mulberry-tree; in French, *Murier*.

The CHARACTERS are,

It hath male flowers growing at separate distances from the female on the same tree. The male flowers are collected in long taper ropes or katkins; these have no petals, but have four awl-shaped erect stamina, which are longer than the empalement, terminated by single summits. The female flowers are collected into roundish beads; these have no petals, but a heart-shaped germen, supporting two long, rough, reflexed styles, crowned by single stigmas. The empalement of these afterward become large, fleshy, succulent fruit, composed of several protuberances, in each of which is lodged one oval seed.

This genus is ranged in the fourth section of Linnæus's twenty-first class, which contains those plants which have male and female flowers at separate distances on the same plant, and the male flowers have four stamina.

The SPECIES are,

1. MORUS (*Nigra*) foliis cordatis. Hort. Cliff. 441. *Mulberry with rough heart-shaped leaves. Morus fructu nigro. C. B. P. 459. Mulberry with a black fruit, or the common Mulberry.*
2. MORUS (*Laciniatis*) foliis palmatis hirsutis. *Mulberry with hand-shaped hairy leaves. Morus fructu nigro minori foliis eleganter laciniatis. Tourn. Inst. R. H. 589. Smaller black Mulberry with elegant cut leaves.*
3. MORUS (*Rubra*) foliis cordatis subtus villosis, amentis cylindricis. Lin. Sp. Plant. 986. *Mulberry with heart-shaped leaves which are hairy on their under side, and cylindrical katkins. Morus Virginienfis arbor, loti arbo-*

ris instar ramosa, foliis amplissimis. Pluk. Phyt. tab. 246. fol. 4. Virginia Mulberry branching like the Nettle-tree, having very large leaves.

4. MORUS (*Alba*) foliis oblique cordatis lævibus. Hort. Cliff. 441. *Mulberry with oblique, smooth, heart-shaped leaves. Morus fructu albo. C. B. P. 459. Mulberry with a white fruit.*
5. MORUS (*Tinctoria*) foliis oblique cordatis acuminatis hirsutis. *Mulberry with oblique, heart-shaped, acute-pointed, hairy leaves. Morus fructu viridi, ligno sulphureo tinctorio. Sloan. Hist. Jam. 2. p. 3. Mulberry with a green fruit, whose wood dyes a sulphur colour, or Fustick wood.*
6. MORUS (*Papyrifera*) foliis palmatis, fructibus hispidis. Lin. Sp. Plant. 986. *Mulberry with hand-shaped leaves and prickly fruit. Morus lativa, foliis urticæ mortuæ, cortice papyrifera. Kæmp. Amoen. 471. Cultivated Mulberry with leaves like Dead Nettle, and of whose bark paper is made.*
7. MORUS (*Tatarica*) foliis ovato-oblongis utrinque æqualibus, inæqualiter serratis. Flor. Zeyl. 337. *Mulberry with oval oblong leaves, which are equal on both sides, but unequally sawed. Tinda-parua. Hort. Mal. 1. p. 87. fol. 49.*
8. MORUS (*Zanthoxylum*) foliis ovato-oblongis acuminatis obliquis, ramis aculeatis. *Mulberry with oval, oblong, acute-pointed leaves, which are oblique to the foot-stalk, and prickly branches. Zanthoxylum aculeatum, carpinifolium, Americanum, cortice cinereo. Pluk. Phyt. 239. fol. 3. Prickly Zanthoxylum of America, with Hornbeam leaves and an Ash-coloured bark.*

The first sort is the common black Mulberry-tree, which is cultivated for the delicacy of its fruit. This tree grows naturally in Persia, from whence it was first brought to the southern parts of Europe, but is now become common in every part of Europe, where the winters are not very severe; for in the northern parts of Sweden, these trees will not live in the open air; and in several parts of Germany they are planted against walls, and treated in the same way as Peach, and other tender fruits are here.

These trees are generally of both sexes, having male flowers or katkins on the same tree with the fruit; but it often happens, that some of the trees which are raised from seeds, have generally male flowers, and produce no fruit; so that those who plant these trees for their fruit, should never make choice of such as have been propagated by seeds, unless they have seen them produce fruit in the nursery. It is also the surest way to mark such trees as are fruitful in the nursery, at the time when their fruit is upon them, because those trees which are propagated by layers, are sometimes of the male sort; for I have several times observed, that some of the large branches of these trees have produced only katkins, when the other parts of the trees have been very fruitful; so that unless care is taken in the choice of the branches for making the layers, there is the same hazard as in seedling trees: nor should the shoots which come out near the roots of old trees be ever laid down, for these rarely produce fruit until they have been planted many years, although the trees from which these were produced might be very fruitful. I have observed some trees which produced only katkins for many years after they were planted, and afterward have become fruitful; the same I have observed in Walnut-trees, and my honoured friend the Chevalier Rathgeb, has informed me, that he has observed the same in the Lentisk and Turpentine-trees.

The old Mulberry-trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; so that where there are any of these old trees, it is the best way to propagate from them, and to make choice of those branches which are most fruitful. The usual method of propagating these trees, is by laying down their branches, which will take root in one year, and are then separated from the old trees; but as the most fruitful branches are often so far from the ground as not be layed, unless by raising of boxes or baskets of earth upon supports for

for this purpose, so the better way is to propagate them by cuttings, which, if rightly chosen and skilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a distance, and from the most fruitful branches. These cuttings should be the shoots of the former year, with one joint of the two years wood to their bottom; the cuttings should not be shortened, but planted their full length, leaving two or three buds above ground. The best season for planting them is in March, after the danger of hard frost is over; they should be planted in light rich earth, pressing the ground pretty close about them; and if they are covered with glasses, it will forward their putting out roots; but where there is not such conveniency, the ground about them should be covered with moss, to prevent its drying; and where this is carefully done, the cuttings will require but little water, and will succeed much better than with having much wet. If the cuttings succeed well and make good shoots, they may be transplanted the following spring into a nursery, where they should be regularly trained to stems, by fixing down stakes by each, to which the principal shoots should be fastened; and most of the lateral branches should be closely pruned off, leaving only two or three of the weakest to detain the sap, for the augmentation of the stem; for when they are quite divested of their side shoots, the sap is mounted to the top, so that the heads of the trees grow too fast for the stems, and become too weighty for their support. In about four years growth in the nursery, they will be fit to transplant where they are to remain; for these trees are transplanted with greater safety while young, than when they are of a large size.

If the cuttings are planted in a bed fully exposed to the sun, it will be proper to arch the bed over with hoops, that they may be shaded with mats in the heat of the day during the spring, till they have put out roots; after which, the more they are exposed to the sun, the better they will succeed, provided the ground is covered with moss or mulch to prevent its drying, for the sun will harden the shoots, and thereby they will be in less danger of suffering by the early frosts in autumn; for when these are in a shady situation, they are apt to grow vigorously in summer, so will be replete with moisture, and the early frosts in October frequently kill their tops; and if the following winter proves severe, they are often killed to their roots, and sometimes are entirely destroyed. I have two or three times made trial of planting the cuttings of Mulberries on a hot-bed, and have found them succeed extremely well. This I was led to by observing some sticks of Mulberry-trees which were cut for forks, and thrust into the hot-bed to fasten down the Vines of Cucumbers; which, although they had been cut from the tree a considerable time, yet many of them put out roots and shot out branches; so that where any person is in haste to propagate these trees, if the cuttings are planted on a moderate hot-bed, they will take root much sooner than in the common ground.

This tree delights to grow in rich light earth, such as is in most of the old kitchen-gardens about London, where there is also a great depth of earth; for in some of those gardens there are trees of a very great age, which are very healthy and fruitful, and their fruit is larger and better flavoured than those of younger trees. I have never yet seen any of these trees which were planted in a very stiff soil, or on shallow ground, either upon clay, chalk, or gravel, which have been healthy or fruitful, but their stems and branches are covered with moss, so that the little fruit which they sometimes produce are small, ill tasted, and late before they ripen.

If these trees are planted in a situation where they are defended from the strong south and north-west winds, it will preserve their fruit from being blown off; but this shelter, whether it be trees or buildings, should be

at such a distance as not to keep off the sun; for where the fruit has not the benefit of his rays to dissipate the morning dews early, they will turn mouldy and rot upon the trees. There is never any occasion for pruning these trees, more than to cut off any of the branches which may grow across others, so as to rub and wound their bark, by their motion occasioned by the wind; for their shoots should never be shortened, because the fruit is produced on the young wood.

The second sort grows naturally in Sicily, from whence I received a parcel of the seeds, and raised a good number of the plants; all these were totally different in their leaves from the common Mulberry, so that I am certain of its being a distinct species. It is also a tree of humbler growth, but the fruit is small and has no flavour, so is not worth propagating; some of the trees produced fruit two or three years in the Chelsea garden.

The white Mulberry is commonly cultivated for its leaves to feed silk-worms in France, Italy, &c. though the Persians generally make use of the common black Mulberry for that purpose; and I have been assured by a gentleman of honour, who has made trial of both sorts of leaves, that the worms fed with those of the black sort produce much better silk than those fed with the white; but he observes that the leaves of the black sort should never be given to the worms after they have eaten for some time of the white, lest the worms should burst, which is often the case when they are thus treated.

The trees which are designed to feed silk-worms, should never be suffered to grow tall, but rather kept in a sort of hedge; and instead of pulling off the leaves singly, they should be sheared off together with their young branches, which is much sooner done, and not so injurious to the tree.

This white sort may be propagated either from seeds or layers, as the black Mulberry, and is equally hardy; but the most expeditious method of raising these trees in quantity, is from the seeds, which may be procured in plenty from the south of France or Italy: the best way to sow these seeds in England, is to make a moderate hot-bed, which should be arched over with hoops, and covered with mats; upon this bed the seeds should be sown in the end of March, and covered over with light earth about a quarter of an inch deep: in very dry weather the bed must be frequently watered, and in the heat of the day shaded with mats, and also covered in the nights when they are cold; with this management the plants will come up in five or six weeks, and as they are tender when they first appear, so they must be guarded against frosty mornings, which often happen in May, and destroy such tender plants; during the summer they must be kept clean from weeds, which is all the culture they require: but there must be care taken of them the first winter, especially to cover them in autumn, when the first frosts come, which will kill the tender plants to the ground, if they are not protected; the following March these plants should be transplanted into the nursery to get strength, where they may remain two or three years, and then should be removed where they are to continue.

There are two or three varieties of this tree, which differ in the shape of their leaves, size, and colour of their fruit; but as they are of no other use than for their leaves, the strongest shooting and the largest leaved should be preferred.

The third sort, which is the large-leaved Virginian Mulberry with black shoots, is more uncommon than either of the former; there is a large tree of this growing in the gardens of the Bishop of London at Fulham, which has been several years an inhabitant of that garden, but has never produced any fruit that I could learn, but hath some years a great number of katkins, much like those of the Hazel-nut, which occasioned Mr. Ray to give it the name of *Corylus*; but it may be one of the male trees which do not produce fruit, as it sometimes happens in the common

sorts

forts of Mulberries; the leaves of this are somewhat like those of the common Mulberry-tree, but are rougher.

This tree has not been propagated yet in this country, for though it has been budded and grafted upon both the black and white Mulberries, yet I cannot hear that it hath succeeded upon either, so that I suspect it is not of this genus; and the tree being pretty tall, cannot be laid down, which is the most likely method to propagate it. This is very hardy, and will endure the cold of our climate in the open air very well, and is coveted as a curiosity by such as delight in a variety of trees and shrubs.

The fifth sort is the tree whose wood is used by the dyers, and is better known by the title of Fustick, which is given to the wood, than by its fruit, which is of no estimation. This grows naturally in most of the islands in the West-Indies; but in much greater plenty at Campeachy, where it abounds greatly. This wood is one of the commodities exported from Jamaica, where it grows in greater plenty than in any other of the British islands.

This tree in the countries where it grows naturally, rises to the height of sixty feet or upward; it has a light brown bark, which hath some shallow furrows; the wood is firm, solid, and of a bright yellow colour. It sends out many branches on every side, covered with a white bark, and are garnished with leaves about four inches long, which are broad at their base, indented at the foot-stalk, where they are rounded, but one side is broader than the other, so that they are oblique to the foot-stalk; these diminish gradually, and end in acute points; they are rough like those of the common Mulberry, of a dark green, and stand upon short foot-stalks. Toward the end of the young branches come out short katkins of a pale herbaceous colour, and in other parts of the same branches the fruit is produced, growing upon short foot-stalks; they are as large as nutmegs, of a roundish form, full of protuberances like the common Mulberry, green within, and also on the outside, of a luscious sweet taste when ripe.

It is too tender to thrive in this country, unless preserved in a warm stove. There are several of the plants now growing in the Chelsea garden, which were raised from seeds sent from Jamaica, by William Williams, Esq; with many other curious sorts, which are natives of that island. The seeds of this plant come up freely on a hot-bed, and when the plants are fit to remove, they should be each planted in a separate small pot filled with fresh light earth, and plunged into a hot-bed of tanners bark, and shaded from the sun till they have taken new root; then they should be treated in the same way as other plants from those hot countries, always keeping them in the tan-bed in the stove, where they will make good progress. These plants retain their leaves great part of the year in the stove.

The sixth sort grows naturally in China and Japan; it also grows naturally in South Carolina, from whence I have received the seeds; the inhabitants of Japan make paper of the bark; they cultivate the trees for that purpose on the hills and mountains, much after the same manner as Osiers are cultivated here, cutting down the young shoots in autumn for their bark. There were several of these trees raised from seeds a few years past, in the gardens of his Grace the Duke of Northumberland, who was so good as to favour me with one of the plants, which thrives very well in the open air without any shelter, as many of the trees and plants of those countries will do, if they grow on the mountains. This plant makes very strong vigorous shoots, but seems not to be of tall growth, for it sends out many lateral branches from the root upward. The leaves are large, some of them are entire, others are deeply cut into three, and some into five lobes, especially while the trees are young, dividing in form of a hand; they are of a dark green, and rough to the touch, but of a pale green, and somewhat hairy on their under side, falling

off on the first approach of frost in autumn, as do those of the common Mulberry. The description which Kæmpfer gives of the fruit is, that they are a little larger than Peas, surrounded with long purple hairs, are composed of acini, or protuberances, and when ripe, change to a black purple colour, and are full of sweet juice.

This tree may be propagated by laying down the branches, in the same way as is practised for the common Mulberry; or it may be multiplied by planting the cuttings, in the same manner as before directed for the common sort.

The seventh sort grows naturally in India, where it becomes a large tree. It hath soft, thick, yellowish bark, with a milky juice like the Fig, which is astringent. The branches come out on every side, which are garnished with oblong oval leaves, standing upon short foot-stalks; both sides of these leaves are equal, but their edges are unequally sawed; they are rough, of a dark green on their upper side, but pale on their under, standing alternately on the branches. The flowers come out in round heads at the foot-stalks of the leaves, on each side the branches; they are of an herbaceous white colour; the male flowers have four stamina; the female flowers are succeeded by roundish fruit, which are first green, afterwards white, and when ripe turn to a dark red colour. I received the seeds of this plant from Bombay, which succeeded in the Chelsea garden. The plants are too tender to live out of a stove in this country; for as I raised a good number of the plants, so when they had obtained strength, I placed some of them in different situations, where they were defended from the frost, but not any of them survived the winter, but those which were in the bark-stove, where they are constantly kept, and treated in the same manner as other tender plants, giving them but little water in winter, with which management the plants thrive, and retain their leaves all the year.

The eighth sort grows naturally in Jamaica, and also in the Bahama Islands, from both which places I have received the seeds. The wood of this tree is cut, and sold for the same uses as the fifth, from which this tree has not been well distinguished by the botanists: this does not grow to so great a size as the fifth; the branches are slenderer, the leaves are narrower, and are rounded at their base, sawed on their edges, and end in acute points. At the foot-stalk of each leaf comes out two sharp thorns, which, in the older branches grow to the length of two inches. The fruit is shaped like that of the fifth sort, but is smaller.

MOSCHATELLINA. See **ADOXA**.

MOSS. See **MUSCUS**.

MOTHERWORT. See **CARDIACA**.

MOULD, or earth, the goodness of which may be known by the sight, smell, and touch.

First, by the sight: those Moulds that are of a bright Chestnut, or hazelly colour, are counted the best; of this colour are the best loams, and also the best natural earth, and this will be the better yet, if it cuts like butter, and does not stick obstinately, but is short, tolerably light, breaking into small clods, is sweet, will be tempered without crusting or chapping, in dry weather, or turning to mortar in wet.

The next to that, the dark gray and russet Moulds are accounted the best, the light and dark Ash-colour are reckoned the worst, such as are usually found on common, or heathy ground; the clear tawny is by no means to be approved, but that of a yellowish red colour is accounted the worst of all; this is commonly found in wild and waste parts of the country, and for the most part produce nothing but Furz and Fern, according as their bottoms are more or less of a light and sandy, or of a spewy gravel, or clayey nature.

Secondly, by the smell: all lands that are good and wholesome, will, after rain, or breaking up by the spade, emit a good smell.

Thirdly, by the touch: by this means we may discover whether it consists of substances entirely arenaceous, or clammy; or, according as it is expressed by

Mr.

Mr. Evelyn, whether it be tender, fatty, deterfive, or slippery, or more harsh, gritty, porous, or friable.

That being always the best that is between the two extremes, and does not contain the two different qualities of soft and hard mixed, of moist and dry, of churlish and mild, that is neither too unctuous or too lean, but such as will dissolve, of a just consistence, between sand and clay, and such as will not stick to the spade or fingers upon every flash of rain.

A loam, or brick Mould, is not to be disapproved, as requiring little help or improvement but the spade, and is esteemed both by the gardener and florist.

MUCILAGE is a viscous clammy substance about seeds, &c.

MUCILAGINOUS signifies, endowed with a clammy viscous matter.

MULBERRY. See **MORUS.**

MULLEIN. See **VERBASCUM.**

MULTISILIQUOUS plants are such as have after each flower, many distinct, long, slender, and, oftentimes, crooked cases, or siliques, in which their seed is contained, and, which, when they ripen, open of themselves, and let the seeds drop. Of this kind is the Bear's-foot, Columbines, common House-leek, Navelwort, Orpine, &c.

MUMMY, a sort of grafting wax, made of one pound of common black pitch, and a quarter of a pound of common turpentine, put into an earthen pot, and set on the fire in the open air; in doing this you ought to hold a cover in your hand, ready to cover it, in order to quench it, by putting it thereon, which is to be done several times, setting it on the fire again, that the nitrous and volatile parts may be evaporated. The way to know when it is enough, is by pouring a little of it on a pewter plate, and if it be so, it will coagulate presently; then this melted pitch is to be poured into another pot, and a little common wax is to be added to it, mixing them well together, and then to be kept for use.

Dr. Agricola directs the using this Mummy as follows:

When you would dress roots with this wax, you must melt it, and afterwards let it cool a little; then dip in the ends of the roots you would plant (for he proposes it for the planting pieces of roots of trees, &c.) one after the other, but not too deep, and afterwards to put them in water, and to plant them in the earth, the small end downwards, so that the larger end may appear a little way out thereof, and have the benefit of the air, and then to press the earth very hard down about them, that they may not receive too much wet, because that would rot them.

Mummy for exotic plants; the same author directs the making it as follows:

Take half a pound of gum copal, beat it very fine, and searce it; take three pounds of Venice turpentine and melt it over a slow fire in a strong earthen pot; when the turpentine is melted and liquidated, put the sifted gum into it, keep it continually stirring with a little stick, augmenting the fire gradually, and it will all dissolve insensibly; afterwards let the turpentine evaporate well, and it will thicken; and when it is become of a sufficient consistence, you may make it up into little rolls, like sealing-wax, and keep it for use.

This Mummy, he says, is an excellent vulnerary for plants, it being subject to no corruption, as other gummy things are; it hinders any rottenness between the stock and the root, by means of which the callus is formed the sooner, and spreads over all the parts, and the stock becomes entirely connected with the root. It also gives strength and vigour to the root, and likewise facilitates it.

Vegetable Mummy; the same author directs the making of this as follows:

Fill a large kettle, or earthen pot, about a third part full of common black pitch, and add to it a little fine resin, or sulphurated pitch, and a little yellow wax; melt these together till they become liquid, then take them off the fire, and let them stand till they have done smoking, and, when cool, you

may, with a brush, plaster the incisions which are made for the inoculation, grafting, &c.

Garden or Forest Mummy; the same author directs the making it as follows:

Take three pounds of common turpentine, and four pounds of common pitch; melt the turpentine over the fire, and, having beaten the pitch to a powder, throw it in, when they are well mixed together, and grown pretty thick, take it off, and keep it for use.

This composition may be either made up into little sticks, like those of sealing-wax, to be made use of on little trees, or it may be kept in little pots, and melted over a slow fire, when there is occasion to use it, and, dipping a little brush in it, you may plaster the graft.

The Noble Mummy, or grafting wax; to make this the same author directs:

Take two pounds of pure pitch, such as is called at Ratibon virgin pitch, and add to it half a pound of good turpentine; put them together in an earthen pot, and set them over the fire, that the volatile part of the turpentine may evaporate, otherwise it would be very prejudicial to trees and roots. Prove it as you did the former, to know when it is enough; then add to it half a pound of virgin wax, and half an ounce of pounded Myrrh and Aloes; when these are well mixed, make it up into little rolls or plasters, or else it may be kept in gallipots.

The time he directs when the operation of the roots is to be performed, is in the month of September, October, and November; though it may succeed well at any time of the year, yet those months are the most proper seasons for it. The only difference he says, is, what is planted in the spring, will shoot out in June or July, and what is planted in autumn comes not forth till the month of April.

The aforesaid author mentions great performances by using these Mummies; those who have a mind to be satisfied, may peruse his treatise.

MUNTINGIA. Plum. Gen. Nov. 41. tab. 6. Lin. Gen. Plant. 575.

The **CHARACTERS** are,

The empalement of the flower is cut into five segments to the bottom. The flower hath five heart-shaped petals, narrow at their base, which are inserted in the empalement, and spread open like a Rose. It has a great number of stamina, which are terminated by roundish summits. In the center is situated a roundish germen, having no style, but is crowned by a stigma divided into many parts. The germen afterward turns to a soft fruit, with one cell, crowned by the stigma, like a navel, and filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, which includes those plants whose flowers have many stamina and one stigma. According to Tournefort's system, it must be ranged in the eighth section of his twenty-first class, which contains the trees and shrubs with a Rose flower, whose empalement becomes a fruit, having hard seeds.

We know but one **SPECIES** of this genus, viz.

MUNTINGIA (*Calabura*.) Jacq. Hist. tab. 107. *Muntingia folio sericeo molli, fructu majori.* Plum. Nov. Gen. 41. *Muntingia with a soft silky leaf, and a larger fruit.*

The title of this genus was given to it by Father Plumier, in honour of Dr Muntingius, who was professor of botany at Groningen in Holland, who published a folio book of botany, entitled, *Phytographia Curiosa*, in which there are many figures of plants exhibited, engraven on copper-plates; he also published two books of plants in quarto, one of which is entitled, *Aloedarum*, in which the figures of several sorts of Aloes are exhibited; the title of the other is, *De Herba Britannica Antiquorum.*

This plant is figured and described by Sir Hans Sloane, in his History of Jamaica, by the title of *Loti arboris folio angustiore, rubi flore, fructu polypermo umbilicato*, 2. p. 80. This rises to the height of thirty feet or more in its native soil, sending out

many branches toward the top, which are covered with a smooth, dark, purple bark, garnished with leaves about three inches long, and three quarters broad at their base, where they are rounded to a heart-shape at the foot-stalk, but end in acute points, are very woolly on their under side, but smooth above, and of a lucid green; they are slightly sawed on their edges, and are placed alternately. The flowers come out from the wings of the stalks, standing upon long foot-stalks, composed of five heart-shaped petals, which are white, and spread open, resembling those of the Bramble, having many stamina about half the length of the petals, terminated by globular summits, and in the center is situated a roundish germen, crowned by a many-pointed stigma. The germen afterward turns to a pulpy umbilicated fruit, as large as the fruit of the Cockspur Hawthorn, and, when ripe, of a dark purple colour, inclosing many small, hard, angular seeds; this sort has produced flowers and fruit in England.

The seeds of this plant were sent by Mr. Robert Millar from Jamaica, which succeeded in some of the English gardens.

The plants are propagated by seeds, which should be sown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, and in warm weather the glasses should be raised to admit fresh air. These seeds will often remain in the ground a whole year before the plants will appear; in which case the pots must be kept constantly clear from weeds, and should remain in the hot-bed till after Michaelmas, when they may be removed into the stove, and plunged into the bark-bed, between other pots of tall plants, where they may remain during the winter season. These pots should be now and then watered, when the earth appears dry, and in the beginning of March the pots should be removed out of the stove, and placed into a fresh bark-bed under frames, which will bring up the plants soon after.

When the plants are come up about two inches high, they should be carefully taken out of the pots, and each planted into a separate small pot filled with light rich earth, and then plunged into the hot-bed again, observing to shade them from the sun until they have taken new root, after which time they should be duly watered, and in warm weather they must have a large share of fresh air. In this hot-bed the plants may remain until autumn, when the nights begin to be cold; at which time they should be removed into the stove, and plunged into the bark-bed. During the winter season these plants must be kept warm, especially while they are young, and frequently refreshed with water; but it must not be given to them in large quantities, lest it rot the tender fibres of their roots. It will be proper to continue these plants in the stove all the year, but in warm weather they should have a large share of fresh air; but as the plants grow in strength, they will be more hardy, and may be exposed in summer for two or three months, and in winter will live in a dry stove, if kept in a moderate degree of heat.

MURUCUIA. See PASSIFLORA.

MUSA. Plum. Nov. Gen. 24. tab. 34. Lin. Gen. Plant. 1010. The Plantain-tree.

The CHARACTERS are,

It hath male and female flowers upon the same foot-stalk, some of which are hermaphrodite; these are produced on a single stalk (or spadix;) the male flowers are situated on the upper part of the spike, and the female below; these are in bunches, each bunch having a sheath, or cover, which falls off. The flowers are of the lip kind. The petals constitute the upper lip, and the nectarium the under; they have six awl-shaped stamina, five of which are situated in the petal, and the sixth in the nectarium; this is double the length of the other, terminated by a linear summit; the others have none. The germen is situated under the flower, which is long, having three obtuse angles, supporting an erect cylindrical style, crowned by a roundish stigma. The germen afterward turns to an ob-

long, three-cornered, fleshy fruit, covered with a thick rind, divided into three parts.

This genus of plants is ranged in the first section of Linnæus's twenty-third class, which includes those plants with male and female flowers, which have hermaphrodite flowers, on the same stalk. Plumier ranges it in Tournefort's class, with the anomalous flowers of several petals; and Garçin places it among the plants with a Lily flower.

The SPECIES are,

1. *MUSA (Paradisifaca) spadice nutante floribus masculis persistentibus. Lin. Sp. 1477. Musa with a nodding spike, and nodding male flowers. Musa fructu cucumerino longiorio. Plum. Nov. Gen. 24. Musa with a longer Cucumber-shaped fruit, commonly called Plantain-tree.*

2. *MUSA (Sapientum) spadice nutante floribus masculis deciduis. Lin. Sp. 1477. Musa with a nodding spike, and deciduous male flowers. Musa fructu cucumerino, breviorio. Plum. Nov. Gen. 24. Musa with a shorter Cucumber-shaped fruit, commonly called Bonana.*

The first sort is cultivated in all the islands of the West-Indies, where the fruit generally serves the negroes for bread, and some of the white people also prefer it to most other sorts, especially to the Yams, and Cassada bread.

This plant rises with a soft herbaceous stalk fifteen or twenty feet high, and upward; the lower part of the stalk is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side, which are often more than six feet long, and near two feet broad, with a strong fleshy midrib, and a great number of transverse veins running from the midrib to the borders. The leaves are thin and tender, so that where they are exposed to the open air, they are generally torn by the wind; for as they are large, the wind has great power against them: these leaves come out from the side of the principal stalk, inclosing it with their base; they are rolled up at their first appearance, but when they are advanced above the stalk, they expand quite flat, and turn backward; as these leaves come up rolled in the manner before mentioned, their advance upward is so quick, that their growth may be almost discerned by the naked eye; and if a line is drawn across, level with the top of the leaf, in an hour's time the leaf will be near an inch above it. When the plant is grown to its full height, the spike of flowers will appear from the center of the leaves, which is often near four feet in length, and nods on one side. The flowers come out in bunches, those on the lower part of the spike being the largest; the others diminish in their size upward; each of these bunches is covered with a spathæ or sheath, of a fine purple colour within, which drops off when the flowers open. The upper part of the spike is made up of male or barren flowers, which are not succeeded by fruit, but those of the second sort fall off with their covers. The fruit of this is eight or nine inches long, and above an inch diameter, a little incurved, and has three angles; it is at first green, but, when ripe, of a pale yellow colour. The skin is tough, and within is a soft pulp of a luscious sweet flavour. The spikes of fruit are often so large as to weigh upwards of forty pounds.

The fruit of the first sort is generally cut before it is ripe, and roasted in the embers, then it is eaten instead of bread. The leaves are used for napkins and table cloths, and are food for hogs.

The second sort, which is commonly called Bonana, differs from the first, in having its stalks marked with dark purple stripes and spots. The fruit is shorter, straighter, and rounder, and the male flowers drop off; the pulp is softer, and of a more luscious taste, so is generally eaten by way of desert, and seldom used in the same way as the Plantain, therefore is not cultivated in such plenty.

Both these plants were carried to the West-Indies from the Canary Islands, to which place it is believed they

they were carried from Guinea, where they grow naturally: these plants are also cultivated in Egypt, and in most other hot countries, where they grow to perfection in about ten months, from their first planting, to the ripening of their fruit; when their stalks are cut down, several suckers come up from the root; they will also produce fruit in ten months after, so that by cutting down the stalks at different times, there is a constant succession of fruit all the year.

In Europe there are some of these plants preserved in the gardens of curious persons, who have hot-houses capacious enough for their reception, in many of which they have ripened their fruit very well; but as they grow very tall and their leaves are large, they require more room in the stove than most people care to allow them: they are propagated by suckers, which come from the roots of those plants which have fruited; and many times the younger plants, when they are stunted in growth, will put out suckers; these should be carefully taken off, preserving some fibres to their roots, and planted in pots filled with light rich earth, and plunged into the tan-bed in the stove: these may be taken off any time in summer, and it is best to take them off when young, because if their roots are grown large, they do not put out new fibres so soon, and when the thick part of the root is cut in taking off, the plants often rot.

During the summer season these plants must be plentifully watered, for the surface of their leaves being large, there is a great consumption of moisture, by perspiration in hot weather, but in the winter they must be watered more sparingly; though at that season they must be often refreshed, but it must not be given them in such quantities.

The pots in which these plants are placed, should be large in proportion to the size of the plants, for their roots generally extend pretty far, and the earth should be rich and light. The degree of heat with which these plants thrive best, is much the same with the Anana, or Pine Apple, in which I have had many of these plants produce their fruit in perfection, and they were near twenty feet high.

The most sure method to have these plants fruit in England is, after they have grown for some time in pots, so as to have made good roots, to shake them out of the pots with the ball of earth to their roots, and plant them into the tan-bed in the stove, observing to lay a little old tan near their roots for their fibres to strike into, and in a few months the roots of these plants will extend themselves many feet each way in the bark; and these plants will thrive a great deal faster than those which are confined in pots, or tubs. When the bark-bed wants to be renewed with fresh tan, there should be great care taken of the roots of these plants, not to cut or break them, as also to leave a large quantity of the old tan about them, because if the new tan is laid too near them, it will scorch their roots, and injure them: these plants must be plentifully supplied with water, otherwise they will not thrive; in winter they should be watered twice a week, giving at least two quarts to each plant, but in summer they must be watered every other day, and double the quantity given to them each time. If the plants push out their flower-stems in the spring, there will be hopes of their perfecting their fruit; but when they come out late in the year, the plants will sometimes decay before the fruit is ripe. The stoves in which these plants are placed should be at least twenty feet in height, otherwise there will not be room for their leaves to expand; for when the plants are in vigour, the leaves are often eight feet in length, and two feet broad: so that if the stems grow to be fourteen feet to the division of the leaves, and the house is not twenty feet high, the leaves will be cramped, which will retard the growth of the plants; besides, when the leaves are bent against the glass, there will be danger of their breaking them, when they are growing vigorously; for I have had in one night the stems of

such bent leaves force through the glass, and by the next morning advanced two or three inches above the glass.

I have seen some bunches of fruit of the first sort, which were upwards of forty pounds weight, and perfectly ripe in England; but this is not so good a fruit, as to tempt any person to be at the expence of raising them in England. The second sort is preferred to the first, for the flavour of its fruit, in all those hot countries where these plants abound: the bunches of these are not near so large as those of the first sort, nor are the single fruit near so long; these change to a deeper yellow colour as they ripen, but their taste is somewhat like that of mealy Figs. Some persons who have resided in the West-Indies, having eaten some of these fruit which were produced in England, and thought them little inferior to those which grew in America; and I imagine, that the inhabitants of those countries would not esteem these fruits so much, had they variety of other sorts; but, for want of better, they eat many kinds of fruit, which would not be valued in Europe, could they be obtained in perfection.

MUSCARI. Tourn. Inst. R. H. 347. tab. 180. Musk, or Grape Hyacinth, vulgò.

The CHARACTERS are,

The flower has no empalement. It hath one oval pitcher-shaped petal, which is reflexed at the brim. It hath three nectariums on the top of the germen, and six awl-shaped stamina which are shorter than the petal, whose summits join together, and in the center is situated a roundish three-cornered germen, supporting a single style, crowned by an obtuse stigma. The germen afterward turns to a roundish three-cornered capsule, having three cells, filled with roundish seeds.

Dr. Linnæus has joined this genus to the Hyacinth, which is placed in the first section of his sixth class, which contains the plants whose flowers have six stamina and one style.

The SPECIES are,

1. MUSCARI (*Botryoide*) corollis globosis uniformibus, foliis canaliculato-cylindricis strictis. *Muscari with uniform globular petals, and cylindrical gutter-shaped leaves. Muscari arvense, juncifolium, cæruleum, minus. Tourn. Inst. 348. Smaller blue Field Muscary, with Rush leaves, commonly called Grape Hyacinth.*
2. MUSCARI (*Comosus*) corollis angulato-cylindricis, summis sterilibus longius pedicellatis. *Muscari with angular cylindrical petals, which on the top of the spike are barren, and have longer foot-stalks. Muscari arvense, latifolium, purpureo-æneum. Tourn. Inst. 347. Broad-leaved, purple, Field Muscari, commonly called Fair-haired Hyacinth.*
3. MUSCARI (*Racemosus*) corollis ovatis, summis sessilibus foliis laxis. *Muscari with oval petals. Muscari obsoletiore flore. Clus. Hist. 1. p. 178. Muscari with an obsolete flower, commonly called Musk Hyacinth.*
4. MUSCARI (*Monstrosus*) corollis subovatis. *Muscari with almost oval corolla. Hyacinthus paniculæ cæruleæ. C. B. P. 42. Blue paniculated Hyacinth, called Feathered Hyacinth.*
5. MUSCARI (*Orchiboide*) corollis sexpartitis, petalis tribus exterioribus brevioribus. *Muscari with petals which are cut into six parts. Hyacinthus orchioides Africanus major bifolius maculatus, flore sulphureo, obsoleto majore. Breyn. Prod. 3. 24. Greater African Hyacinth, resembling Orchis, with two spotted leaves, and a larger, obsolete, sulphur-coloured flower.*

The first sort grows naturally in the vineyards and arable fields in France, Italy, and Germany, and where it is once planted in a garden, it is not easily rooted out, for the roots multiply greatly, and if they are permitted to scatter their seeds, the ground will be filled with the roots. There are three varieties of this, one with blue, another with white, and a third with Ash-coloured flowers: the first sort hath a small, round, bulbous root, from which come out many leaves about six inches long, which are narrow, and their edges are incurved, so as to be shaped like a gutter: between these arise the flower-stalk, which

is naked, and toward the top garnished with a close spike of blue flowers, shaped like pitchers, sitting very close to the stalk; these smell like fresh starch, or the stones of Plumbs which are fresh. They flower in April, and the seeds ripen the latter end of June.

The second sort grows naturally in Spain and Portugal, from whence I have received both roots and seeds; this hath a bulbous root as large as a middling Onion, from which come out five or six leaves a foot long, and three quarters of an inch broad at their base, diminishing gradually to a point. The flower-stalk rises about a foot high, the lower half naked, but the upper is garnished with cylindrical, angular, purple flowers, standing upon foot-stalks half an inch long; these grow horizontally, but the stalk is terminated by a tuft of flowers whose petals are oval, and have neither germen or style, so are barren. This sort flowers the latter end of April, or the beginning of May; there is a variety of this with white, and another with blue flowers, but the purple is the most common.

The third sort hath pretty large, oval, bulbous roots, from which arise several leaves, which are about eight or nine inches long, and half an inch broad; they are incurved a little on their sides, and end in obtuse points; these embrace each other at their base; out of the middle of these, the stalk which sustains the flowers arises; they are naked below, but their upper parts are garnished with small flowers growing in a spike; these have oval pitcher-shaped petals, which are reflexed at their brim, and are of an Ash-coloured purple, or obsolete colour, seeming as if faded, but have an agreeable musky scent: these stalks do not rise more than six inches high, so the flowers make no great appearance; but where they are in some quantity, they will perfume the air to a considerable distance. This sort flowers in April, and the seeds ripen in July.

Of this there are two varieties, one of which has the same coloured flowers with this here enumerated, on the lower part of the spike, but they are larger, and have more of the purple cast, but the flowers on the upper part of the spike are yellow, and have a very grateful odour. The Dutch gardeners title it Tibcadi Muscari. As this is supposed to be only a seminal variety of the third, I have not enumerated it as distinct. There is another variety of this with very large yellow flowers, that has been lately raised from seeds in Holland, which the florists there sell for a guinea a root.

The fourth sort hath a large bulbous root, from which come out several plain leaves a foot long, and about half an inch broad at their base; they are smooth, and end in obtuse points. The flower-stalks rise near a foot and a half high; they are naked at the bottom for about seven or eight inches, above which the panicles of flowers begin, and terminate the stalks. The flowers stand upon foot-stalks which are more than an inch long, each sustaining three, four, or five flowers, whose petals are cut into slender filaments like hairs; they are of a purplish blue colour, and have neither stamina or germen, so do never produce seeds. It flowers in May, and, after the flowers are past, the stalks and leaves decay to the root, and new ones arise the following spring.

The fifth sort grows naturally at the Cape of Good Hope, from whence I received the seeds, which succeeded in the Chelsea garden, where the plants have flowered for several years past; this hath a small, white, bulbous root, about the size of a Hazel nut, from which comes out generally but two, (though sometimes when the roots are strong) three leaves, which are five or six inches long, and one inch and a half broad in the middle, ending in obtuse points; these are of a lucid green, and have many spots, or protuberances on their upper surface. The flower-stalk rises between them to the height of six or seven inches, it is round, smooth, and naked for three inches

high or more, and is terminated by a spike of flowers, which are of a pale sulphur colour; these have no foot-stalks; they have one petal, which is of an irregular figure, and cut at the top into six parts. The stamina are almost equal with the petal, and stand round the style, which is of the same length. The flowers appear in March, but are seldom succeeded by good seeds here.

The four first sorts are very hardy, so will thrive in the open air, and require no other culture than any other hardy bulbous-rooted flower; which is, to take up their roots every second or third year to separate their bulbs, for as some of the sorts multiply pretty fast, so when they are become large bunches, they do not flower so strong as when they are single: the best time to take them out of the ground, is soon after their stalks and leaves are decayed; then they should be spread on a mat, in a dry shady room for a fortnight to dry, after which they may be kept in boxes like other bulbous roots, till Michaelmas, when they may be planted again in the borders of the flower-garden, and treated in the same way as the common hardy kinds of Hyacinths.

The first sort should not be admitted into the flower-garden, because the roots will propagate so fast, as to become a troublesome weed there.

The second sort has but little beauty, so a few of these only should be allowed a place merely for the sake of variety; this is so hardy, as to thrive in any soil or situation.

The third sort merits a place for the extreme sweetness of its flowers, but especially that variety of it with yellow flowers, called Tibcady.

The fourth sort may also be allowed to have place in the common borders of the pleasure-garden, where they will add to the variety, and are by no means to be despised.

They are all easily propagated by offsets, which most of their roots send out in pretty great plenty, so that there is little occasion for sowing of their seeds, unless it be to gain some new varieties.

The fifth sort is too tender to thrive in the open air in England, so the roots must be planted in small pots, filled with light rich earth; and in the autumn they should be placed under a hot bed-frame, where they may be protected from frost, but should have as much free air as possible in mild weather; for when these are placed in a green-house, their leaves are drawn long and narrow, and the flower-stalks are generally weak, so never flower so well as when they have plenty of free air. These flowers will continue a month where they are not drawn, but will decay in half that time in a green-house.

These roots should be transplanted in July, when their stalks and leaves are decayed, and should be placed in the open air during the summer season, but should have very little water when their leaves are decayed.

MUSCIPULA. See *SILENE*.

MUSCOSE, MUSCOSUS, Mossy, or abounding with Moss.

MUSCOSITY, Mossiness.

MUSCUS, Moss.

These, though formerly supposed to be only excrescences produced from the earth, trees, &c. yet are no less perfect plants than those of greater magnitude, having roots, branches, flowers, and seeds, but yet cannot be propagated from the latter by any art.

The botanists distinguish these into several genera, under each of which are several species; but as they are plants of no use or beauty, it would be to little purpose to enumerate them in this place.

These plants chiefly flourish in cold countries, and in the winter season, and are many times very injurious to fruit-trees, which grow upon cold barren soils, or where they are so close planted as to exclude the free access of air. The only remedy in such cases is to cut down part of the trees, and plough up the ground between those left remaining: and in the spring

spring of the year, in moist weather, you should, with an iron instrument made a little hollow, the better to surround the branches of the trees, scrape off the Moss, carrying it off the place; and by two or three times thus cleansing them, together with carefully stirring the ground, it may be entirely destroyed from the trees; but if you do not cut down part of the trees, and stir the ground well, the rubbing off the Moss will signify little; for the cause not being removed, the effect will not cease, but the Moss will in a short time be as troublesome as ever.

MUSHROOMS are, by many persons, supposed to be produced from the putrefaction of the dung, earth, &c. in which they are found; but notwithstanding this notion is pretty generally received amongst the unthinking part of mankind, yet by the curious naturalists, they are esteemed perfect plants, though their flowers and seeds have not as yet been perfectly discovered. But since they may, and are annually propagated by the gardeners near London, and are (the esculent sort of them) greatly esteemed by most curious palates, I shall briefly set down the method practised by the gardeners who cultivate them for sale.

But first, it will not be improper to give a short description of the true eatable kind, since there are several unwholesome sorts, which have been by unskilful persons gathered for the table.

The true Champignon, or Mushroom, appears at first of a roundish form, like a button; the upper part of which, as also the stalk, is very white; but being opened, the under part is of a livid flesh colour, but the fleshy part when broken is very white; when these are suffered to remain undisturbed, they will grow to a large size, and explicate themselves almost to a flatness, and the red part underneath will change to a dark colour.

In order to cultivate them, if you have no beds in your own, or in neighbouring gardens, which produce them, you should look abroad in rich pastures, during the months of August and September, until you find them (that being the season when they are naturally produced;) then you should open the ground about the roots of the Mushrooms, where you will find the earth, very often, full of small white knobs, which are the offsets, or young Mushrooms; these should be carefully gathered, preserving them in lumps with the earth about them: but as this spawn cannot be found in the pasture, except at the season when the Mushrooms are naturally produced, you may probably find some in old dunghills, especially where there has been much litter amongst it, and the wet hath not penetrated it to rot it; as likewise, by searching old hot-beds, it may be often found; for this spawn has the appearance of a white mould, shooting out in long strings, by which it may be easily known wherever it is met with: or this may be procured by mixing some long dung from the stable, which has not been thrown on a heap to ferment; which being mixed with strong earth, and put under cover to prevent wet getting to it, the more the air is excluded from it, the sooner the spawn will appear; but this must not be laid so close together as to heat, for that will destroy the spawn: in about two months after the spawn will appear, especially if the heap is closely covered with old thatch, or such litter as hath lain long abroad, so as not to ferment, then the beds may be prepared to receive the spawn: these beds should be made of dung, in which there is good store of litter, but this should not be thrown on a heap to ferment; that dung which hath lain spread abroad for a month or longer, is best. These beds should be made on dry ground, and the dung laid upon the surface; the width of these beds at bottom should be about two feet and a half or three feet, the length in proportion to the quantity of Mushrooms desired; then lay the dung about a foot thick, covering it about four inches with strong earth. Upon this lay more dung, about ten inches thick; then another layer of earth, still drawing in the sides of the bed, so

as to form it like the ridge of a house, which may be done by three layers of dung and as many of earth. When the bed is finished it should be covered with litter or old thatch, to keep out wet, as also to prevent its drying; in this situation it may remain eight or ten days, by which time the bed will be in a proper temperature of warmth to receive the spawn; for there should be only a moderate warmth in it, great heat destroying the spawn, as will also wet; therefore when the spawn is found, it should always be kept dry until it is used, for the drier it is, the better it will take in the bed; for I had a parcel of this spawn, which had lain near the oven of a stove upward of four months, and was become so dry, that I despaired of its success; but I never have yet seen any which produced so soon, nor in so great quantity as this.

The bed being in a proper temperature for the spawn, the covering of litter should be taken off, and the sides of the bed smoothed; then a covering of light rich earth about an inch thick should be laid all over the bed, but this should not be wet; upon this the spawn should be thrust, laying the lumps four or five inches asunder; then gently cover this with the same light earth above half an inch thick, and put the covering of litter over the bed, laying it so thick as to keep out wet, and prevent the bed from drying: when these beds are made in the spring or autumn, as the weather is in those seasons temperate, so the spawn will then take much sooner, and the Mushrooms will appear perhaps in a month after making; but those beds which are made in summer, when the season is hot, or in winter, when the weather is cold, are much longer before they produce.

The great skill in managing of these beds is, that of keeping them in a proper temperature of moisture, never suffering them to receive too much wet: during the summer season the beds may be uncovered, to receive gentle showers of rain at proper times; and in long dry seasons the beds should be now and then gently watered, but by no means suffer much wet to come to them; during the winter season they must be kept as dry as possible, and so closely covered as to keep out cold. In frosty or very cold weather, if some warm litter shaken out of a dung heap is laid on, it will promote the growth of the Mushrooms; but this must not be laid next the bed, but a covering of dry litter between the bed and this warm litter; and as often as the litter is found to decay, it should be renewed with fresh; and as the cold increases, the covering should be laid so much thicker. If these things are observed, there may be plenty of Mushrooms produced all the year; and these produced in beds, are much better for the table than any of those which are gathered in the fields.

A bed thus managed, if the spawn takes kindly, will continue good for several months, and produce great quantities of Mushrooms; from these beds when they are destroyed, you should take the spawn for a fresh supply, which may be laid up in a dry place until the proper season of using it, which should not be sooner than five or six weeks, that the spawn may have time to dry before it is put into the bed, otherwise it will not succeed well.

Sometimes it happens, that beds thus made do not produce any Mushrooms till they have lain five or six months, so that these beds should not be destroyed, though they should not at first answer expectation; for I have frequently known these to have produced great quantities of Mushrooms afterward, and have continued a long time in perfection.

MUSTARD. See SINAPI.

MYAGRUM. Tourn. Inst. R. H. 211. tab. 99. Lin. Gen. Plant. 713. Gold of Pleasure.

The CHARACTERS are,

The empalement of the flower is composed of four oblong, oval, coloured leaves, which fall off. The flower hath four roundish obtuse petals, placed in form of a cross. It hath six stamina the length of the petals, four of which are a little longer than the other, terminated by single summits.

mits. In the center is situated an oval germen, supporting slender style, crowned by an obtuse stigma. The germen afterward becomes a turbinated, heart-shaped, short pod, having two valves with a rigid style on the top, inclosing roundish seeds.

This genus of plants is ranged in the first section of Linnaeus's fifteenth class, which contains the plants whose flowers have four long and two shorter stamina, and the seeds are inclosed in short small pods.

The SPECIES are,

1. MYAGRUM (*Sativum*) siliculis ovatis, pedunculatis polyspermis. Hort. Cliff. 328. *Myagrum with oval pods having foot-stalks, inclosing several seeds. Alysson segetum foliis auriculatis acutis.* Tourn. Inst. R. H. *Corn Madwort with eared acute-pointed leaves, commonly called Gold of Pleasure.*
2. MYAGRUM (*Alyssum*) siliculis cordatis pedunculatis polyspermis, foliis denticulatis obtusis. *Myagrum with heart-shaped pods standing upon foot-stalks, having many seeds and indented leaves. Alysson segetum foliis auriculatis acutis fructu majori.* Tourn. Inst. 217. *Corn Madwort, with acute-eared leaves and a larger fruit.*
3. MYAGRUM (*Rugosum*) siliculis globosis compressis punctato-rugosis. Hort. Cliff. 328. *Myagrum with globular, compressed, small pods, having rough punctures. Rapisstrum arvense, folio auriculato acuto.* Tourn. Inst. 211. *Field Charlock with an acute-eared leaf.*
4. MYAGRUM (*Perenne*) siliculis biarticulatis dispermis, foliis extrorsum sinuatis denticulatis. Hort. Upsal. 182. *Myagrum with short pods, having two joints and two seeds, and outer leaves which are sinuated and indented. Rapisstrum monospermum.* C. B. P. 95. *One-seeded Charlock.*
5. MYAGRUM (*Perfoliatum*) siliculis obcordatis subsefilibus, foliis amplexicaulibus. Hort. Upsal. 182. *Myagrum with small heart-shaped pods sitting close to the stalk, and the leaves embracing it. Myagrum monospermum latifolium.* C. B. P. 109. *Broad-leaved Myagrum having one seed in a pod.*

The first sort grows naturally in Corn fields in the south of France and Italy; I have also found it growing in the Corn in Easthamsted-park, the seat of William Trumbull, Esq; but it is not common in this country. It is an annual plant, with an upright stalk about a foot and a half high, sending out two or four side branches toward the top, which grow erect; they are smooth, and have a fungous pith; the lower leaves are from three to four inches long, of a pale or yellowish green, and are eared at their base; those upon the stalks diminish in their size all the way up, and are entire, and almost embrace the stalks with their base. The flowers grow in loose spikes at the end of the branches, standing upon foot-stalks an inch long; they are composed of four small yellowish petals, placed in form of a cross; these are succeeded by oval capsules, which are bordered, and crowned at the top with the style of the flower, having two cells, which are filled with red seeds.

The second sort is also an annual plant, and differs from the first in having a taller stalk; the leaves are much longer, narrower, and are regularly indented on their edges, ending in obtuse points. The flowers are larger, but of the same form and colour; the capsules are much larger, and are shaped like a heart. Both these plants flower in June and July, and their seeds ripen in September.

The third sort grows naturally on the borders of arable fields, in the south of France and Italy. This is an annual plant, whose lower leaves are five or six inches long; they are hairy and succulent; their base is eared, and they end in acute points. The stalks rise a foot and a half high, they are brittle and hairy, branching out toward the top like the two former, and are terminated by short loose spikes of small pale flowers, which are succeeded by small, rough, roundish capsules, compressed at the top. It flowers in July, and the seeds ripen in autumn.

The fourth sort grows naturally amongst the Corn, in France and Germany. This is also an annual

plant; the lower leaves are large, jagged, and hairy; the stalks branch out from the bottom, and are garnished with leaves about four inches long and two broad; they are hairy, and unequally jagged. The stalks are terminated by very long loose spikes of yellow flowers, which are succeeded by short pods with two joints, each including one roundish seed. It flowers about the same time with the former.

The fifth sort grows naturally in the south of France and Italy; this hath a smooth branching stalk upward of two feet high; the lower leaves are five or six inches long, smooth, succulent, and a little indented; the upper leaves almost embrace the stalks with their base. The flowers are produced in long loose spikes, which are yellow, and sit close to the stalk; these are succeeded by heart-shaped compressed pods, divided into two cells by a longitudinal partition, each containing one roundish seed. It flowers at the same time with the former.

If the seeds of all these plants are permitted to scatter in the autumn, the plants will rise without any care, and only require to be thinned and kept clean from weeds. These autumnal plants will always ripen their seeds, whereas those which are sown in the spring sometimes fail.

MYOSOTIS. Dill. Gen. 3. Lin. Gen. 180. Mouse-ear.

The CHARACTERS are,

The flower hath an oblong, erect, permanent empalement, cut into five points; the flower is salver-shaped, having a short cylindrical tube, cut into five obtuse segments at the brim; the chaps are closed by five small scales which join, and are prominent. It hath five short stamina in the neck of the tube, terminated by small summits; and four germen supporting a slender style the length of the tube, crowned by an obtuse stigma; the germen afterward become four oval seeds inclosed in the empalement.

This genus of plants is ranged in the first section of Linnaeus's fifth class, intitled Pentandria Monogynia, the flower having five stamina and one style.

The SPECIES are,

1. MYOSOTIS (*Virginica*) feminibus aculeatis glochidibus, foliis ovato-oblongis, ramis divaricatis. Lin. Sp. 189. *Mouse-ear with prickly seeds, oblong oval leaves, and divaricated branches. Cynoglossum Virginianum, flore & fructu minimo.* Mor. Hist. 3. tab. 30. fol. 9. *Virginian Hound's-tongue, with small flowers and seeds.*
2. MYOSOTIS (*Lappula*) feminibus aculeis glochidibus, foliis lanceolatis pilosis. Flor. Suec. 150. *Mouse-ear with prickly seeds, and hairy spear-shaped leaves. Cynoglossum minus.* C. B. P. 257. *Smaller Hound's-tongue.*
3. MYOSOTIS (*Apula*) feminibus nudis, foliis hispidis, racemis foliolis. Lin. Sp. 189. *Mouse-ear with naked seeds, stinging leaves, and leafy branches. Echium luteum minimum.* C. B. P. 254. *The least yellow Viper's Bugloss.*

There are one or two other species of this genus which grow naturally in England, so are rarely admitted into gardens, therefore are omitted here: and those here enumerated are seldom cultivated except in botanic gardens, being plants of little beauty or use. Those persons who are desirous of keeping them, should sow their seeds in the autumn, upon an open bed or border of light earth, and in the spring thin the plants where they are too close, and keep them clean from weeds, which is all the culture they require; and if their seeds are permitted to scatter, the plants will rise without farther trouble.

MYOSURUS, Mouse-tail.

This plant is very near a-kin to the Ranunculus, in which genus it is ranged by some botanists; the flowers are extremely small, and are succeeded by long slender spikes of seeds, resembling the tail of a mouse, from whence it had the name. It grows wild upon moist grounds in divers parts of England, where it flowers the latter end of April; and the seeds ripen in a month after, when the plants decay, being annual. It is rarely cultivated in gardens, so I shall not trouble the reader with any further account of it.

M Y R I C A. Lin. Gen. Plant. 981. Gale. Tourn. Art. Reg. Scien. 1706. The Candleberry Myrtle, Gale, or Sweet Willow; by some Myrtus Brabantica, or Dutch Myrtle; in French, *Piment Royal*.

The CHARACTERS are,

The male flowers are upon different plants from the female; the male flowers are produced in a loose, oblong, oval katkin, imbricated on every side; under each scale is situated one moon-shaped flower, having no petal, but bath four or six short slender stamina, terminated by large twin summits, whose lobes are bifid. The female flowers have neither petal or stamina, but an oval germen supporting two slender styles, crowned by single stigmas. The germen afterward becomes a berry with one cell, inclosing a single seed.

This genus of plants is ranged in the fourth section of Linnaeus's twenty-second class, which includes the plants whose male flowers have four stamina, and are upon different plants from the fruit.

The SPECIES are,

1. **MYRICA** (Gale) foliis lanceolatis subserratis, caule fruticoso. Lin. Sp. Plant. 1024. *Myrica with spear-shaped sawed leaves and a shrubby stalk.* Gale frutex odoratus septentrionalium. J. B. 1. p. 2. 225. *Northern, shrubby, sweet Gale, sweet Willow, Dutch Myrtle, or Gale.*
2. **MYRICA** (Cerifera) foliis lanceolatis subserratis, caule arborescente. Kalm. *Myrica with spear-shaped leaves, and a shrubby stalk.* Myrtus Brabanticae similis Carolinensis baccifera, fructu racemoso sessili monopyreno. Pluk. Phyt. tab. 48. fol. 9. *Carolina Myrtle like that of the Dutch, with berries growing in bunches, and sitting close to the stalks, commonly called Candleberry Myrtle.*
3. **MYRICA** (Carolinensis) foliis lanceolatis serratis, caule suffruticoso. *Myrica with spear-shaped sawed leaves, and a shrubby stalk.* Myrtus Brabanticae similis Carolinensis humilior, foliis latioribus & magis serratis. Catesb. Car. vol. i. p. 13. *Lower Carolina Myrtle, or Candleberry-tree resembling that of Brabant, having broader leaves which are more sawed.*
4. **MYRICA** (Asplenifolia) foliis oblongis alternatim sinuatis. Hort. Cliff. 456. *Myrica with oblong oval leaves, which are alternately sinuated.* Gale Mariana Asplenii folio. Pet. Mus. 773. *Maryland Gale with a Spleenwort leaf.*
5. **MYRICA** (Quercifolia) foliis oblongis oppositè sinuatis glabris. *Myrica with oblong smooth leaves, which are oppositely sinuated.* Laurus Africana minor, folio quercus. Hort. Amst. 2. p. 161. *Smaller African Bay with an Oak leaf.*
6. **MYRICA** (Hirsuta) foliis oblongis oppositè sinuatis hirsutis. *Myrica with oblong hairy leaves, which are oppositely sinuated.*
7. **MYRICA** (Cordifolia) foliis subcordatis serratis sessilibus. Hort. Cliff. 456. *Myrica with sawed leaves which are almost heart-shaped, and sit close to the stalk.* Gale Capensis, ilicis cocciferae folio. Pet. Mus. 774. *Gale from the Cape, with a leaf like the Kermes Oak.*

The first sort grows naturally upon bogs in many parts of England, particularly in the northern and western counties, as also in Windsor-park, and near Tunbridge-wells. This rises with many shrubby stalks near four feet high, which divide into several slender branches, garnished with stiff spear-shaped leaves, about an inch and a half long, and half an inch broad in the middle; they are of a light or yellowish green, smooth, and a little sawed at their points, and emit a fragrant odour when bruised; they are placed alternately on their branches. The male flowers or katkins are produced from the side of the branches, growing upon separate plants from the female, which are succeeded by clusters of small berries, each having a single seed. It flowers in July, and the seeds ripen in autumn.

The leaves of this shrub has been by some persons gathered and used for Tea, but it is generally supposed to be hurtful to the brain; but from this use of it, a learned physician a few years since, wrote a treatise to prove this to be the true Tea, in which

he has only shewn his want of knowledge in these things.

It grows naturally in bogs, so cannot be made to thrive on dry land, for which reason it is seldom preserved in gardens.

The second sort grows naturally in North America, where the inhabitants get a sort of green wax from the berries, which they make into candles. The method of collecting and preparing this, is described by Mr. Catesby, in his History of Carolina.

This grows naturally in bogs and swampy lands, where it rises with many strong shrubby stalks eight or ten feet high, sending out several branches, garnished with stiff spear-shaped leaves near three inches long, and one broad in the middle; they are smooth and entire, having scarce any foot-stalks, of a yellowish lucid green on their upper side, but paler on their under, standing alternately, and pretty close to the branches; these have a very grateful odour when bruised. The katkins come out upon different plants from the berries; these are about an inch long, standing erect. The female flowers come out on the side of the branches in longish bunches, which are succeeded by small roundish berries, covered with a sort of meal. This shrub delights in a moist soft soil, in which it thrives extremely well, and lives in the open air without any protection.

The third sort grows naturally in Carolina; this doth not rise so high as the former, the branches are not so strong, and they have a grayish bark; the leaves are shorter, broader, and are sawed on their edges, but in other respects is like the second sort; the berries of this are also collected for the same purpose.

These sorts are propagated by seeds, which should be sown in the autumn, and then the plants will come up the following spring; but if the seeds are kept out of the ground till the spring, they seldom grow till the year after. These plants will require water in dry weather, and should be screened from frosts while young, but when they have obtained strength, they will resist the cold of this country very well.

The fourth sort grows naturally in Philadelphia, from whence many of the plants have been brought to England, and those which have been planted on a moist soil have thriven very well; some of these creep at their roots, and send up suckers plentifully, in the same manner as in their native soil.

This rises with slender shrubby stalks near three feet high, which are hairy, and divide into several slender branches, which are garnished with leaves from three to four inches long, and half an inch broad; they are alternately indented almost to the midrib, and have a great resemblance to those of Spleenwort; they are of a dark green, hairy on their under side, and sit close to the stalks. The male flowers or katkins come out on the side of the branches between the leaves; these are oval, and stand erect. I have not seen any of these plants in fruit, so I can give no description of it.

This sort may be propagated by suckers, which are sent out from the roots when it is planted in a loose moist soil, and will endure the cold full as well as the two former sorts.

The fifth and sixth sorts grow naturally at the Cape of Good Hope; these only differ from each other, in one having very smooth shining leaves, and those of the other hairy. I do not know if they are really different species, but as I received them from Holland as such, and the plants still retaining their difference, so I have enumerated them both.

These rise with shrubby slender stalks about four feet high, which divide into smaller branches, which in one sort are smooth, and in the other they are hairy; these are closely garnished with leaves about an inch and a half long, and almost an inch broad; some having two, others three, deep indentures on their sides, which are opposite; in one sort they are smooth and shining, and in the other they are hairy, and of a darker green; they sit close to the branches, and

end

end in obtuse points which are indented : between the leaves come out some oval katkins, which drop off, so that all the plants which I have seen have been male, therefore I can give no account of the fruit. These retain their leaves all the year, but are too tender to live through the winter in the open air in England, so must be placed in the green-house in winter. As these do not produce seeds here, so they are propagated by layers, but they do not take root very freely, so that the plants are not very common in Europe at present ; for I do not find that the cuttings of these plants will easily take root, having made several trials of them in all the different methods ; nor have the Dutch gardeners had better success, so that the plants are as scarce there as in England.

When the layers are laid down, that part of the shoot which is laid should be tongued at a joint, as is practised in laying of Carnations ; and the young shoots only should be chosen for this purpose, for the old branches will not put out roots. These layers are often two years before they will have taken root enough to transplant, for they should not be separated from the old plants till they have made good roots, because they are very subject to miscarry if they are not well rooted.

When they are taken off from the old plants, they should be each put into a separate small pot, filled with soft, rich, loamy earth ; and if they are placed under a common frame, shading them from the sun in the middle of the day, it will forward their taking new root ; then they may be placed in a sheltered situation during the summer, and in the autumn removed into the green-house, and treated in the same way as other plants from the same country. The best season for laying down the branches, I have observed to be in July, and by the same time the following year they have been fit to remove.

The seventh sort is a native of the Cape of Good Hope ; this hath a weak shrubby stalk which rises five or six feet high, sending out many long slender branches, which are closely garnished their whole length with small heart-shaped leaves, which sit close to the branches, and are slightly indented and waved on their edges. The flowers come out between the leaves in roundish bunches ; these are male in all the plants I have yet seen ; they have an uncertain number of stamina, and are all included in one common scaly involucre or cover. These flowers appear in July, but make no great appearance ; the leaves of this sort continue all the year green.

This is propagated in the same way as the two former sorts, and is difficult to increase, so is not common in the European gardens. It requires the same treatment as the two former sorts.

MYRRHIS. See CHÆROPHYLLUM, SCANDIX, SISON.

MYRTUS. Tourn. Inst. R. H. 640. tab. 409. Lin. Gen. Plant. 543. Myrtle ; in French, *Mirte*.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five acute points at the top, is permanent, and sits on the germen. The flower has five large oval petals which are inserted in the empalement, and a great number of small stamina which are also inserted in the empalement, terminated by small summits. The germen is situated under the flower, supporting a slender style, crowned by an obtuse stigma. The germen afterward turns to an oval berry with three cells, crowned by the empalement, each cell containing one or two kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnæus's twelfth class, in which is contained those plants whose flowers have about twenty stamina and one style.

The SPECIES are,

1. MYRTUS (*Communis*) foliis ovatis, pedunculis longioribus. Myrtle with oval leaves, and longer foot-stalks to the flowers. Myrtus latifolia Romana. C. B. P. 468. Broad-leaved Roman Myrtle, or common broad-leaved Myrtle.
2. MYRTUS (*Belgica*) foliis lanceolatis acuminatis. Myrtle with spear-shaped acute-pointed leaves. Myrtus la-

tifolia Belgica. C. B. P. 469. Broad-leaved Dutch Myrtle.

3. MYRTUS (*Acuta*) lanceolato-ovatis acutis. Myrtle with spear-shaped, oval, acute-pointed leaves. Myrtus sylvestris, foliis acutissimis. C. B. P. 469. Wild Myrtle with very acute-pointed leaves.

4. MYRTUS (*Bætica*) foliis ovato-lanceolatis confertis. Myrtle with oval spear-shaped leaves growing in clusters. Myrtus latifolia Bætica 2 vel foliis laurinus, confertim nascentibus. C. B. P. 469. Second broad-leaved Spanish Myrtle, with Bay leaves growing in clusters, commonly called Orange-leaved Myrtle.

5. MYRTUS (*Italica*) foliis ovato-lanceolatis acutis, ramis erectioribus. Myrtle with oval, acute-pointed, spear-shaped leaves, and erect branches. Myrtus communis Italica. C. B. P. 468. Common Italian Myrtle, called upright Myrtle.

6. MYRTUS (*Tarentina*) foliis ovatis, baccis rotundioribus. Myrtle with oval leaves and rounder berries. Myrtus minor vulgaris. C. B. P. 469. Common smaller Myrtle, called the Box-leaved Myrtle.

7. MYRTUS (*Minima*) foliis lineari-lanceolatis acuminatis. Myrtle with linear, spear-shaped, acute-pointed leaves. Myrtus foliis minimis & mucronatis. C. B. P. 469. Myrtle with the smallest sharp-pointed leaves, commonly called Rosemary-leaved Myrtle.

8. MYRTUS (*Zeylanica*) pedunculis multifloris, foliis ovatis subpetiolatis. Lin. Sp. Plant. 472. Myrtle with many flowers on each foot-stalk, and oval leaves having short foot-stalks. Myrtus Zeylanica odoratissima, baccis niveis monococcis. H. L. 434. Sweet-smelling Myrtle of Ceylon, with snow white berries containing one seed. The first sort is the common broad-leaved Myrtle, which is one of the hardiest kinds we have. The leaves of this are an inch and a half long, and one inch broad, of a lucid green, standing upon short foot-stalks. The flowers are larger than those of the other sorts, and come out from the side of the branches, on pretty long foot-stalks ; these are succeeded by oval berries of a dark purple colour, inclosing three or four hard kidney-shaped seeds. It flowers in July and August, and the berries ripen in winter. This sort is by some called the flowering Myrtle, because it generally has a greater quantity of flowers, and those are larger than of any other sort.

The second sort has leaves much less than those of the former, and are more pointed, standing closer together on the branches ; the midrib on the under side of the leaves is of a purple colour, they are of a darker green, and sit closer to the branches. The flowers are smaller, and have shorter foot-stalks than those of the first sort ; this flowers a little later in the summer, and seldom ripens its berries here.

The double flowering Myrtle I take to be a variety of this, for the leaves and growth of the plant, the size of the flowers, and the time of flowering, agree better with this than any of the other sorts.

The third sort grows naturally in the south of France and in Italy ; the leaves of this are much smaller than those of the second, being less than an inch long, and not more than half an inch broad, of an oval spear-shape, ending in acute points, of a dull green, and set pretty close on the branches. The flowers are smaller than either of the former, and come out from the wings of the leaves toward the end of the branches ; the berries are small and oval.

The fourth sort hath a stronger stalk and branches than either of the former sorts, and rises to a greater height ; the leaves are oval, spear-shaped, and are placed in clusters round the branches ; these are of a dark green. The flowers are of a middling size, and come out sparingly from between the leaves ; the berries are oval, and smaller than those of the first sort, but seldom ripens in England. The gardeners call this the Orange-leaved Myrtle, and by some it is stiled the Bay-leaved Myrtle. This sort is not so hardy as the former.

The fifth sort is the common Italian Myrtle ; this hath oval spear-shaped leaves, ending in acute points ; the branches of this grow more erect than those of either

ther of the former sorts, as do also the leaves, from whence it is called by the gardeners upright Myrtle. The flowers of this sort are not large, and the petals are marked with purple at their points, while they remain closed; the berries are small, oval, and of a purple colour. There is a variety of this with white berries, in which it only differs from this; and I believe the Nutmeg Myrtle is only a variety of this, for I have raised several of the plants from seed, many of which were so like the Italian Myrtle, as not to be distinguished from it.

The sixth sort is commonly called the Box-leaved Myrtle; the leaves of this are oval, small, and sit close on the branches; they are of a lucid green, ending in obtuse points; the branches are weak, and frequently hang downward, when they are permitted to grow without shortening, and have a grayish bark. The flowers are small, and come late in the summer, the berries are small and round.

The seventh sort is called the Rosemary-leaved Myrtle, and by some it is called the Thyme-leaved Myrtle. The branches of this grow pretty erect; the leaves are placed close on the branches; they are small, narrow, and end in acute points; they are of a lucid green, and have a fragrant odour when bruised. The flowers of this are small, and come late in the season, and are but seldom succeeded by berries here.

There are some other varieties of these Myrtles, which are propagated in the gardens for sale; but as their difference has been occasioned by culture, so it would be multiplying their titles to little purpose. Those which are here enumerated I believe to be really distinct, for I have raised most of them from seeds, and have not found them change from one to another, though there has been other small variations among the plants.

The eighth sort is a native of the Island of Ceylon: this is much tenderer than either of the former sorts, so cannot be kept through the winter in England, without some artificial heat. This hath a strong upright stalk, covered with a smooth gray bark, dividing upward into many slender stiff branches, garnished with oval leaves placed opposite, which are near two inches long, and an inch and a quarter broad, ending in points; they are of a lucid green, and have very short foot-stalks. The flowers come out at the ends of the branches, several of them being sustained upon one common foot-stalk, which branches out, and each flower stands on a very slender distinct foot-stalk; they are very like the flowers of Italian Myrtle, but always appear in December and January, and are never succeeded by berries here.

I shall first treat of the method of cultivating and propagating the common sorts of Myrtle, as they all require nearly the same management, and shall afterward take notice of that of the last mentioned, which require a different treatment; but as the varieties of the common sorts of Myrtle are cultivated in the gardens for sale, I shall just mention the titles by which they are known, that the curious may be informed how many there are.

Two sorts of Nutmeg Myrtles, one with a broader leaf than the other.

The Bird's Nest Myrtle, the striped Nutmeg Myrtle, the striped upright Myrtle, the striped Rosemary-leaved Myrtle, the striped Box-leaved Myrtle, and the striped broad-leaved Myrtle.

These plants may be all propagated from cuttings, the best season for which is in the beginning of July, when you should make choice of some of the straightest and most vigorous young shoots, which should be about six or eight inches long, and the leaves on the lower part must be stripped off about two or three inches high, and the part twisted which is to be placed in the ground; then having filled a parcel of pots (in proportion to the quantity of cuttings designed) with light rich earth, you should plant the cuttings therein, at about two inches distance from each other, observing to close the earth fast about them, and give them some water to settle it to the cuttings; then place the

pots under a common hot-bed frame, plunging them either into some old dung, or tanners bark, which will prevent the earth from drying too fast; but you must carefully shade them with mats in the heat of the day, and give them air in proportion to the warmth of the season, not forgetting to water them every two or three days, as you shall find the earth in the pots require it.

With this management, in about six weeks, the cuttings will be rooted, and begin to shoot, when you must inure them to the open air by degrees, into which they should be removed towards the latter end of August, or the beginning of September, placing them in a situation where they may be sheltered from cold winds, in which place they may remain till the middle or latter end of October, when the pots should be removed into the green-house, but should be placed in the coolest part thereof, that they may have air given to them whenever the weather is mild, for they require only to be protected from severe cold, except the Orange-leaved, and the striped Nutmeg Myrtles, which are somewhat tenderer than the rest, and should have a warmer situation.

During the winter season, they must be frequently, but gently watered; and, if any decayed leaves appear, they should be constantly picked off, as also the pots kept clear from weeds, which, if permitted to grow, will soon overspread the young plants, and destroy them.

If these pots are placed under a common hot-bed frame in winter, where they may be screened from frost, and have the free air in mild weather, the young plants will succeed better than in a green-house, provided they do not receive too much wet, and are not kept closely covered, which will occasion their growing mouldy, and dropping their leaves.

The spring following these plants should be taken out of the pots very carefully, preserving a ball of earth to the roots of each of them, and every one should be placed into a separate small pot filled with rich light earth, observing to water them well to settle the earth to their roots, and place them under a frame until they have taken root; after which they should be inured to the open air, and in May they must be placed abroad for the summer, in a sheltered situation, where they may be defended from strong winds.

During the summer season they will require to be plentifully watered, especially being in such small pots, which in that season soon dry; therefore you should observe to place them where they should receive the morning sun, for when they are too much exposed to the sun in the heat of the day, the moisture contained in the earth of these small pots will soon be exhaled, and the plants greatly retarded in their growth thereby.

In August following you should examine your pots, to see if the roots of the plants have not made way out through the hole in the bottom of the pots, which if you observe, you must then shift them into pots a size larger, filling them up with the like rich earth, and observe to trim the roots which were matted to the side of the pots, as also to loosen the earth from the outside of the ball with your hands, some of which should be taken off, that the roots may the easier find passage into the fresh earth; then you must water them well, and place the pots in a situation where they may be defended from strong winds; and at this time you may trim the plants, in order to reduce them to a regular figure; and if they are inclinable to make crooked stems, you should thrust down a slender straight stick close by them, to which their stems should be fastened, so as to bring them upright.

If care be taken to train them thus while they are young, the stems afterward, when they have acquired strength, will continue straight without any support, and their branches may be pruned, so as to form either balls or pyramids, which for such plants as are preserved in the green-house, and require to be kept in

small compass, is the best method to have them handsome; but then these sheered plants will not produce any flowers, for which reason that sort with double flowers should not be clipped, because the chief beauty of that consists in its flowers; but it will be necessary to suffer a plant or two of each kind to grow rude, for the use of their branches in nosegays, &c. for it will greatly deface those which have been constantly sheered to cut off their branches.

As these plants advance in stature, they should annually be removed into larger pots, according to the size of their roots; but you must be careful not to put them into pots too large, which will cause them to shoot weak, and many times prove the destruction of them; therefore when they are taken out of the former pots, the earth about their roots should be pared off, and that within side the ball must be gently loosened, that the roots may not be too closely confined; and then place them into the same pots again, provided they are not too small, filling up the sides and bottom of them with fresh rich earth, and giving them plenty of water to settle the earth to their roots; which should be frequently repeated, for they require to be often watered both in winter and summer, but in hot weather they must have it in plenty.

The best season for shifting these plants is either in April or August, for if it be done much sooner in the spring, the plants are then in a slow growing state, and so not capable to strike out fresh roots again very soon; and if it be done later in autumn, the cold weather coming on will prevent their taking root; nor is it advisable to do it in the great heat of summer, because they will require to be very often watered, and also to be placed in the shade, otherwise they will be liable to droop for a considerable time; and that being the season when these plants should be placed amongst other exotics, to adorn the several parts of the garden, these plants, being then removed, should not be exposed until they have taken root again, which, at that time (if the season be hot and dry) will be three weeks or a month.

In October, when the nights begin to be frosty, you should remove the plants into the green-house; but if the weather proves favourable in autumn (as it often happens) they may remain abroad until the beginning of November; for if they are carried into the green-house too soon, and the autumn should prove warm, they will make fresh shoots at that season, which will be weak, and often grow mouldy in winter, if the weather should be so severe as to require the windows to be kept closely shut, whereby they will be greatly defaced; for which reason they should always be kept as long abroad as the season will permit, and removed out again in the spring before they shoot out; and during the winter season that they are in the green-house, they should have as much free air as possible when the weather is mild.

The three first-mentioned sorts I have seen planted abroad in warm situations, and upon a dry soil, where they have endured the cold of our winters for several years very well, with only being covered in very hard frosts with two or three mats, and the surface of the ground about their roots covered with a little mulch to prevent the frost from entering the ground; but in Cornwall and Devonshire, where the winters are more favourable than in most other parts of England, there are large hedges of Myrtle which have been planted several years, and are very thriving and vigorous, some of which are upward of six feet high; and I believe, if the double flowering kind were planted

abroad, it would endure the cold as well as any of the other sorts, it being a native of the southern parts of France. This, and the Orange-leaved kind, are the most difficult to take root from cuttings; but if they are planted toward the latter end of June, making choice of only such shoots as are tender, and the pots are plunged into an old bed of tanners bark which has lost most of its heat, and the glasses shaded every day, they will take root extremely well, as I have more than once experienced. The Orange-leaved sort, and those with variegated leaves, are somewhat tenderer than the ordinary sorts, and should be housed a little sooner in autumn, and placed farther from the windows of the green-house.

The eighth sort is at present rare in Europe, so is in very few gardens. This sort was by Dr. Linnaeus separated from the Myrtles in the former editions of his works, and had the title of *Myrsine* applied to it; but in his *Species of Plants*, he has joined it to that genus again, to which, according to his system, it properly belongs; for the number of petals, stamina, and style, do agree with those of the Myrtle, but it differs in fructification, this having but one seed in each fruit, and the Myrtle has four or five.

This plant is with difficulty propagated, which occasions its present scarcity, for as it does not produce ripe seeds in Europe, it can only be increased by layers or cuttings. By the former method the layers are commonly two years before they take root, and the cuttings frequently fail, though the latter is preferred, when performed at a proper season and in a right method; the best time to plant the cuttings is in May: in the choice of them, it should be the shoots of the former year, with a small piece of the two years wood at bottom; these should be planted in small pots, filled with soft loamy earth, for small pots are to be preferred to large ones for this purpose, and they should be plunged into a very moderate hot-bed of tanners bark; and if the pots are each covered with small bell or hand-glasses, such as have been used for blowing of Carnations to exclude the air, it will be of great service to promote the cuttings putting out roots, though they are covered with the glasses of the hot-bed above them; the cuttings should be shaded from the sun in the heat of the day, and gently refreshed with water, as the earth in the pots is found to dry, but they should by no means have too much wet; those cuttings which succeed, will have taken root by July, when they should be gradually inured to bear the open air, into which it will be proper to remove them about the middle of that month, that they may be strengthened before winter, but it will not be proper to transplant the cuttings till spring; the pots must be removed into a temperate stove in autumn, and during the winter the cuttings must be gently refreshed with water. In the spring they should be carefully taken up, and each planted in a small pot filled with light earth from a kitchen-garden, and plunged into a moderate hot-bed to forward their taking fresh root; then they should be gradually hardened, and in July placed in the open air in a sheltered situation, where they may remain till the end of September, and then be removed into the stove.

This plant will not live through the winter in England in a green-house, but if it is placed in a moderate degree of warmth, it will flower well in winter; and in July, August, and September, the plants should be placed abroad in a sheltered situation.

 NAPÆA. Lin. Gen. Plant. 748. Malva. H. L.

The CHARACTERS are,

It hath male and hermaphrodite flowers in distinct plants. The male flowers have pitcher-shaped empalements of one leaf, which are permanent, and cut at the top into five segments. The flowers have five oblong petals, which are connected at their base, but spread open, and are divided at the top; they have many hairy stamina, which are joined at the bottom into a sort of a cylindrical column, terminated by roundish compressed summits. The hermaphrodite flowers have the like empalement, petals, and stamina, as the male, and have a conical germen, supporting a cylindrical style, divided at the top into ten parts, crowned by single stigmas. The germen afterward turns to an oval fruit, inclosed in the empalement, divided into ten cells, each containing one kidney-shaped seed.

This genus of plants is ranged in the third section of Linnæus's sixteenth class, which includes the plants whose flowers have many stamina, which are joined at their base to the style, and together form a column. As the plants of this genus have male and hermaphrodite flowers on distinct plants, so they differ from all the tribe of malvaceous plants, to which they properly belong, the flowers being monopetalous, the stamina and styles being joined at their base, forming a column, which are the essential characters of that class.

The SPECIES are,

1. **NAPÆA** (*Dioica*) pedunculis involucri angulatis foliis scabris, floribus dioicis. Flor. Virg. 102. *Napæa with angular foot-stalks, rough leaves, and male and hermaphrodite flowers on different plants. Abutilon folio profundè dissecto, pedunculis multifloris mas & fœmina. Ehret. Pict. 7 & 8. Abutilon with a deeply divided leaf, and foot-stalks having many flowers, which are both male and female.*
2. **NAPÆA** (*Hermaphrodita*) pedunculis nudis lævibus, foliis glabris, floribus hermaphroditis. *Napæa with naked foot-stalks, smooth leaves and hermaphrodite flowers. Althæa Ricini folio Virginiana. H. L. Virginia Marsh-mallow with a Ricinus leaf.*

The first sort has perennial roots, which are composed of many thick fleshy fibres, which strike deep into the ground, and are connected at the top into a large head, from which come out a great number of rough hairy leaves, near a foot diameter each way, which are deeply cut into six or seven lobes, which are irregularly indented on their edges, each lobe having a strong midrib, which all meet in a center at the foot-stalk. The foot-stalks are large and long, arising immediately from the root, and spread out on every side. The flower-stalks rise seven or eight feet high, and divide into smaller branches, garnished at each joint with one leaf, of the same form as those below, but diminish in their size toward the top, where they seldom have more than three lobes, which are divided to the foot-stalk; toward the upper part of the stalk come out from the side at each joint a long foot-stalk, which branches out toward the top, sustaining several white flowers, which are tubulous at bottom, where the segments of the petal are connected, but they spread open above, and are divided into five ob-

N A R

tuse segments; in the center arises the column, to which the stamina are joined at their base, but spread open above, and in the hermaphrodite flowers the style is connected to the same column. The hermaphrodite flowers are succeeded by compressed orbicular fruit, inclosed in the empalement, and divided into five cells, each containing a kidney-shaped seed, but the male plants are barren. It flowers in July and the seeds ripen in autumn, soon after which the stalk decays, but the roots will live many years.

The second sort hath also a perennial root, which frequently creeps in the ground; this sends up smooth stalks, which rise about four feet high, garnished with smooth leaves, placed alternately, standing upon pretty long slender foot-stalks; they are deeply cut into three lobes, which end in acute points, and are irregularly sawed on their edges; those on the lower part of the stalk are near four inches long, and almost as much in breadth, but they diminish gradually toward the top of the stalk. At the base of the leaf comes out the foot-stalk of the flower, which is about three inches long, dividing at the top into three smaller, each sustaining one white flower of the same form with those of the first sort, but are smaller, and the column of stamina is longer, their summits standing out beyond the petal.

Both these plants grow naturally in Virginia, and other parts of North America; from the bark of these plants might be procured a sort of hemp, which many of the malvaceous tribe afford; and in some of the sorts which grow naturally in India, the fibres of the bark are so fine, as to spin into very fine threads, of which there might be woven very fine cloth.

These plants are easily propagated by seeds, which if sown on a bed of common earth in the spring, the plants will rise very freely, and will require no other care but to keep them clear from weeds till autumn, when they may be transplanted into the places where they are to remain; they delight in a rich moist soil, in which they will grow very luxuriantly, so they must be allowed room. The second sort may be propagated by its creeping roots, which may be parted in autumn; but as these plants have no great beauty, so one or two of each sort in a garden, for the sake of variety, will be enough.

NARCISSO LEUCOIUM. See GALANTHUS.
NARCISSUS. Lin. Gen. Plant. 364. [takes its name of *ναρξος*, or *ναρκη*, a torpidness, or deep sleep, because the smell of this flower is said to cause a heaviness of the head, and a stupidity. Plutarch tells us, this plant was sacred to the infernal gods. The poets tell us, that Narcissus was the son of Cephissus, and the nymph Lyriope; a youth of such excellent beauty, that once upon a time coming to a fountain to drink, and seeing his beauteous image in the water, he grew so enamoured with it that he pined away with desire, and was transformed into a flower of his name.] The Daffodil.

The CHARACTERS are,

The flowers are included in an oblong compressed spathe (or sheath) which tears open on the side, and withers. The flowers have a cylindrical funnel-shaped empalement of one leaf, which is spread open at the brim; they have six oval petals on the outside of the nectarium, which are inserted above their base, and six awl-shaped stamina fixed

to the tube of the nectarium, terminated by oblong summits; they have a three-cornered, roundish, obtuse germen, situated below the flower, supporting a long slender style, crowned by a trifid stigma. The germen afterward turns to an obtuse, roundish, three-cornered capsule, with three cells, filled with globular seeds.

This genus of plants is ranged in the first section of Linnaeus's sixth class, which contains those plants whose flowers have six stamina and one style.

The SPECIES are,

1. NARCISSUS (*Pseudonarcissus*) *spathâ uniflorâ, nectario campanulato erecto, crispo æquante petala ovata.* Lin. Sp. Plant. 414. *Daffodil with one flower in each sheath, whose nectarium is erect, bell-shaped, and equal with the petals, which are oval.* *Narcissus sylvestris pallidus, calyce luteo.* C. B. P. 52. *Pale wild Daffodil with a yellow cup, or common English Daffodil.*
2. NARCISSUS (*Poëticus*) *spathâ uniflorâ, nectario rotato brevissimo, scariofo crenulato.* Hort. Upsal. 74. *Daffodil with one flower in a sheath, having a very short wheel-shaped nectarium indented on the edge.* *Narcissus albus, circulo purpureo.* C. B. P. 48. *White Daffodil with a purple circle in the middle.*
3. NARCISSUS (*Incomparibilis*) *spathâ uniflorâ, nectario campanulato erecto, petalo dimidio brevior.* *Daffodil with one flower in a sheath, having an erect bell-shaped empalement half the length of the petal.* *Narcissus incomparibilis, flore pleno, partim flavo, partim croceo.* H. R. Par. *The Incomparable Daffodil with a double flower, partly yellow, and partly Saffron-coloured.*
4. NARCISSUS (*Medio-luteus*) *spathâ biflorâ, nectarii campanulato, brevissimo, floribus nutantibus.* *Daffodil with two flowers in a sheath, a short bell-shaped nectarium, and nodding flowers.* *Narcissus medio luteus vulgaris.* Park. *Common Daffodil with a yellow middle, called Primrose Peerless.*
5. NARCISSUS (*Albus*) *spathâ uniflorâ, nectario campanulato brevissimo, petalis reflexis.* *Daffodil with one flower in a sheath, having a very short bell-shaped nectarium, and reflexed petals.* *Narcissus albus, foliis reflexis, calyce brevi aureo.* H. R. Par. *Daffodil with white flowers, having reflexed petals, and a short golden cup.*
6. NARCISSUS (*Bulbocodium*) *spathâ uniflorâ, nectario turbinato petalis majore, genitalibus declinatis.* Lin. Sp. Plant. 417. *Rush-leaved Daffodil with one flower in each sheath, a turbinated nectarium larger than the petal, and declining stamina.* *Pseudonarcissus juncifolius flavo flore.* Clus. Hist. 166. *Commonly called Hoop-petticoot Narcissus.*
7. NARCISSUS (*Serotinus*) *spathâ uniflorâ, nectario brevissimo sex-partito.* Læsl. Lin. Sp. Plant. 290. *Daffodil with one flower in a sheath, having a very short nectarium, which is cut into six parts.* *Narcissus autumnalis minor.* Clus. Hist. 251. *Smaller autumnal Daffodil.*
8. NARCISSUS (*Tazetta*) *spathâ multiflorâ, nectario campanulato, foliis planis.* Hort. Upsal. 74. *Daffodil with many flowers in a sheath, having a bell-shaped nectarium, and plain leaves.* *Narcissus luteus polyanthos Lusitanicus.* C. B. P. 50. *Yellow Portugal Daffodil with many flowers, commonly called Polyanthus Narcissus.*
9. NARCISSUS (*Jonquilla*) *spathâ multiflorâ, nectario campanulato brevi, foliis subulatis.* Hort. Upsal. 75. *Daffodil with many flowers in a sheath, a short bell-shaped nectarium, and awl-shaped leaves.* *Narcissus juncifolius luteus minor.* C. B. P. 51. *Smaller yellow Rush-leaved Daffodil, called Jonquil.*

The sorts here enumerated, are all the real species which I have met with in the English gardens, though there is a great variety of each species, which differ so much from one another, as to render it very difficult to ascertain the species to which they belong; in order to find out, as well as I could, from what species many of those varieties have been raised, I endeavoured to degenerate as many of the double flowering, and others of the best kinds, so far as I could, by which I have observed their several changes, and

shall here mention under each species, the varieties I have observed.

The first sort is the common English Daffodil, which grows naturally by the borders of woods and fields in many parts of England; this hath a large bulbous root, from which comes out five or six flat leaves, about a foot long, and an inch broad, of a grayish colour, and a little hollowed in the middle like the keel of a boat. The stalk rises a foot and a half high, having two sharp longitudinal angles; at the top comes out a single flower, inclosed in a thin spatha (or sheath), which is torn open on one side, to make way for the flower to come out, and then withers and remains on the top of the stalk. The flower is of one petal or leaf, being connected at the base, but is cut into six parts almost to the bottom, which expand; in the middle of this is situated a bell-shaped nectarium, called by the gardeners a cup, which is equal in length to the petal, and stands erect. The flower nods on the side of the stalk. The petal is of a pale brimstone colour, and the nectarium yellow. It flowers the beginning of April, and after the flowers are past, the germen turns to a roundish capsule, with three cells filled with roundish black seeds, which ripen in July. This sort propagates very fast by offsets from the root.

The varieties of this are,

One with white petals, and a pale yellow cup.

One with yellow petals, and a golden cup.

The common double yellow Daffodil.

Another double Daffodil, with three or four cups within each other.

And, I believe, John Tradescant's Daffodil may be referred to this species.

The second sort grows naturally in the south of France and in Italy; this hath a smaller and rounder bulbous root than the former. The leaves are longer, narrower, and flatter than those of that sort. The stalks do not rise higher than the leaves, which are of a gray colour: at the top of the stalk comes out one flower from the sheath, which nods on one side. The petal of this is cut into six segments, which are rounded at their points; they are of a snow white, and spread open flat. In the center is situated a very short nectarium or cup, which is fringed on the border with a bright purple circle. The flowers have an agreeable odour. This flowers in May, but seldom produces seeds, however it increases fast enough by offsets.

The double white Narcissus is the only variety of this which I have observed, though there is mentioned in some books several other.

The third sort grows naturally in Spain and Portugal, from whence I have received the roots. The bulbs of this sort are very like those of the first. The leaves are longer, of a darker green, and the flower-stalks rise higher. The segments of the petal are rounder, and spread open, flatter than those of the first sort. The nectarium, or cup, in the middle, is about half the length of the petal, and is edged with a gold-coloured fringe. It flowers in April, but seldom produces seeds here. This sort sports and varies more than any of the other: the following variations I have traced in the same roots.

The roots of these, the first year, produced very double flowers, of the sort which is commonly called the Incomparable Daffodil. The six outer segments of the petal were longer than either of the others, and white; the middle was very full of shorter petals, some of which were white, others yellow, and collected into a globular figure: some of these roots, the following year, produced flowers less double than before, with no white petals in them, but the larger petals were of a sulphur colour, and the others yellow; from this they afterward degenerated to half double flowers, and at last to single flowers, with a cup half the length of the petal, in which manner they have continued to flower many years; so that we may conclude, that those varieties were first obtained from the seeds of this single flower.

The

The fourth sort grows naturally in the south of France and in Italy, and has been found growing in the fields in some parts of England, but it is likely to have been from some roots which have been thrown out of gardens with rubbish. The roots of this sort are not so large as those of the first, and are rounder; the leaves are long, of a gray colour, and smoother than those of the first; the flower-stalks are of the same length with the leaves, and have commonly but one flower in a sheath, but sometimes when the roots are strong, they have two. The flower nods downward, the segments of the petal are a little waved on their edges, the nectarium or cup is short, and bordered with yellow; it flowers in May. The scent of these flowers is not very agreeable, and as they are not very beautiful, so they are seldom cultivated in gardens, since the finer sorts have been plenty. There is no variety of this so far as I have been able to trace, for I could never observe any variation in the flowers.

The fifth sort has some resemblance of the fourth, but the flowers are whiter, the segments of the petal are reflexed, and the border of the nectarium or cup is of a gold yellow colour; this has some affinity to the second sort.

The sixth sort grows naturally in Portugal, from whence I have received the roots. The bulbs of this kind are small, the leaves are very narrow, having some resemblance to those of the Rush, but are a little compressed, and have a longitudinal furrow on one side; these are seldom more than eight or nine inches long. The flower-stalk is slender, taper, and about six inches long, sustaining at the top one flower, which is at first inclosed in a sheath; the petal is scarce half an inch long, and is cut into six acute segments; the nectarium or cup is more than two inches long, very broad at the brim, lessening gradually to the base, being somewhat formed like the ladies hoop petticoats, from whence the flower is so called. It flowers in April, but does not produce seeds here. There are no varieties of this sort.

The seventh sort grows naturally in Spain; this hath a small bulbous root; the leaves are but few in number, and are narrow; the stalk is jointed, and rises about nine inches high, sustaining at the top one flower, which at first is inclosed in the spatha, or sheath; the flower is cut into six narrow segments, which are white; the nectarium, or cup, is yellow. It flowers late in the autumn, and the roots are tender, so are often killed by hard frosts in England, which renders it scarce here.

The eighth sort grows naturally in Portugal, and in the islands of the Archipelago: of this there are a greater variety than of all the other species; for as the flowers are very ornamental, and come early in the spring, so the florists in Holland, Flanders, and France, have taken great pains in cultivating and improving them; so that at present the catalogues printed by the Dutch florists, contain more than thirty varieties, the principal of which are these hereafter mentioned.

These have yellow petals, with Orange, yellow, or sulphur-coloured cups, or nectariums.

The Great Algiers.	The Most Beautiful.
The Ladies Nofegay.	The Golden Star.
The Greater Bell.	The Mignon.
The Golden Royal.	The Zeylander.
The Golden Scepter.	The Madoufe.
The Triumphant.	The Golden Sun.

The following have white petals, with yellow or sulphur-coloured cups or nectariums.

The Archdutchefs.	The Greater Bozelman.
The Triumphant Nofegay.	The Czarina.
The New Dorothy.	The Grand Monarque.
The Passe Bozelman.	The Czar of Muscovy.
The Superb.	The Surpassante.

There are some with white petals and white cups, but these are not so much esteemed as the others,

though there are two or three varieties with large bunches of small white flowers, which have a very agreeable odour, so are as valuable as any of the other, and are later in flower than most of the other sorts. There is also one with very double flowers, whose outer petals are white, and those in the middle are some white, and others of an Orange-colour, which have a very agreeable scent, and is the earliest in flowering; it is generally called the Cyprus Narcissus, and seems to be a distinct species from the others. This, like most other double flowers, never produces any seeds, so is only propagated by offsets, and is the most beautiful of all the Narcissus, when blown upon glasses of water in a room; but when it is planted in the ground, if the bed in which they are planted is not covered with mats in frosty weather, to prevent their flower-buds from being destroyed, they seldom flower; for the leaves begin to shoot early in the autumn, and the flower-buds appear about Christmas, which are tender, so that if hard frost happen when they are coming out of the ground, it generally kills them; but if they are properly screened from frost, they will flower in February, and in mild seasons often in January.

The ninth sort is the Jonquil, a flower so well known as to need no description; of this there is the great and small Jonquil with single flowers, and the common sort with double flowers, which is most esteemed.

I shall first treat of the method for raising the fine sorts of Polyanthus Narcissus from seeds, which is the way to obtain new varieties.

The not practising this has occasioned our sending abroad annually for great quantities of flower-roots, which have been kept up to a high price, on account of the great demand for them in England; whereas if we were as industrious to propagate them as our neighbours, we might soon vie with them, if not out-do them, in most sorts of flowers; as may be seen, by the vast variety of Carnations, Auriculas, Ranunculas, &c. which have been produced from seeds in England, and exceed most of those kinds in any part of Europe.

You must be very careful in saving your seeds, to gather none but from such flowers as have good properties, and particularly from such only as have many flowers upon a stalk, that flower tall, and have beautiful cups to their flowers; from such you may expect to have good flowers produced; but if you sow ordinary seed, it is only putting yourself to trouble and expence to no purpose, since from such seeds there can be no hopes of procuring any valuable flowers.

Having provided yourself with good seeds, you must procure either some shallow cases or flat pans, made on purpose for the raising of seedlings, which should have holes in their bottoms, to let the moisture pass off; these must be filled with fresh, light, sandy earth about the beginning of August (that being the season for sowing the seeds of most bulbous-rooted flowers;) the earth in these must be levelled very even; then sow the seeds thereon pretty thick, covering them over with fine sifted light earth about half an inch thick, and place the cases or pans in a situation where they may have only the morning sun till about ten o'clock, where they should remain until the beginning of October, when they must be removed into a warmer situation, placing them upon bricks, that the air may freely pass under the cases, which will preserve them from being too moist.

They should also be exposed to the full sun, but screened from the north and east winds; and if the frost should be severe, they must be covered, otherwise there will be danger of their being destroyed; in this situation they may remain until the beginning of April, by which time the plants will be up, when you must carefully clear them from weeds; and if the season should prove dry, they must be frequently watered: the cases should also now be removed into their former shady position, or shaded in the middle

of the day, for the heat of the noon-day sun will be too great for the young plants.

The latter end of June, when the leaves of the plants are decayed, you should take off the upper surface of the earth in the cases (which by that time will have contracted a mossiness, and, if suffered to remain, will greatly injure the young roots) observing not to take it so deep as to touch the roots; then sift some fresh light earth over the surface, about half an inch thick, which will greatly strengthen the roots; the same should also be repeated in October, when the cases are moved again into the sun.

During the summer season, if the weather should prove very wet, and the earth in the case appear very moist, you must remove them into the sun till the earth be dry again; for if the roots receive much wet during the time they are inactive, it very often rots them; therefore you must never give them any water after their leaves are decayed, but only place them in the shade, as was before directed.

Thus you should manage them the two first seasons, till their leaves are decayed; but the second summer after sowing, you should carefully take up the roots; which may be done, by sifting the earth in the cases through a fine sieve, whereby the roots will be easily separated from the earth; then having prepared a bed or two of good fresh light earth, in proportion to the quantity of your roots, you should plant them therein, at about three inches distance every way, and about three inches deep in the ground.

These beds should be raised above the level of the ground, in proportion to the moisture of the soil, which if dry, three inches will be enough; but if it be wet, they must be raised six or eight inches high, and laid a little rounding, to shoot off the wet.

If these beds are made in July, which is the best time to transplant the roots, the weeds will soon appear very thick; therefore you should gently hoe the surface of the ground to destroy them, being very careful not to cut so deep as to touch any of the roots; and this should be repeated as often as may be found necessary, by the growth of the weeds, observing always to do it in dry weather, that they may be effectually destroyed; and toward the latter end of October, after having entirely cleared the beds from weeds, you should sift a little rich light earth over them, about an inch thick; the goodness of which will be washed down to the roots by the winter's rain, which will greatly encourage their shooting in the spring.

If the cold should be very severe in winter, you should cover the beds either with old tan or sea coal ashes, or in want of these with Pease-haulm, or some such light covering, to prevent the frost from penetrating the ground to the roots, which might greatly injure them while they are so young.

In the spring, when the plants begin to appear above ground, you must gently stir the surface of the ground, clearing it from weeds, &c. in doing of which, you should be very careful not to injure the plants; and if the season should prove dry, you should now and then gently refresh them with water, which will strengthen the roots.

When their leaves are decayed, you should clear the beds from weeds, and sift a little earth over them (as was before directed) which must also be repeated in October, in like manner; but the roots should not remain longer in these beds than two years, by which time they will have grown so large as to require more room; therefore they should be taken up as soon as their leaves are decayed, and planted into fresh beds, which should be dug deep, and a little very rotten dung buried in the bottom, for the fibres of the roots to strike into. Then the roots should be planted at six inches distance, and the same depth in the ground. In the autumn, before the frost comes on, if some rotten tan is laid over the beds, it will keep out the frost, and greatly encourage the roots; and if the winter should prove severe, it will be proper to lay a greater thickness of tan over the beds, and also in the alleys, to keep out frost, or to cover them over with

Straw, or Pease-haulm, otherwise they may be all destroyed by the cold. In the spring these coverings should be removed, as soon as the danger of hard frosts is over, and the beds must be kept clean from weeds the following summer: at Michaelmas they should have some fresh earth laid over the beds, and covered again with tan, and so every year continued till the roots flower, which is generally in five years from seed, when you should mark all such as promise well, which should be taken up as soon as their leaves decay, and planted at a greater distance in new prepared beds; but those which do not flower, or those you do not greatly esteem, should be permitted to remain in the same bed; therefore, in taking up those roots which you marked, you must be careful not to disturb the roots of those left, and also to level the earth again, and sift some fresh earth over the beds (as before) to encourage the roots; for it often happens in the seedlings of these flowers, that at their first time of blowing, their flowers seldom appear half so beautiful as they do the second year; for which reason none of them should be rejected until they have flowered two or three times, that so you may be assured of their worth.

Thus having laid down directions for the sowing and managing these roots, until they are strong enough to flower, I shall proceed to give some instructions for planting and managing the roots afterwards, so as to cause them to produce large fair flowers.

All the sorts of Narcissus which produce many flowers upon a stalk, should have a situation defended from cold and strong winds, otherwise they will be subject to be injured by the cold in winter, and their stems broken down when in flower; for notwithstanding their stalks are generally pretty strong, yet the number of flowers upon each renders their heads weighty, especially after rain, which lodges in the flowers, and, if succeeded by strong winds, very often destroys their beauty, if they are exposed thereto; so that a border under a hedge, which is open to the south-east, is preferable to any other position for these flowers.

The morning sun rising upon them will dry off the moisture which had lodged upon them the preceding night, and cause them to expand fairer than when they are planted in a shady situation; and if they are too much exposed to the afternoon sun, they will be hurried out of their beauty very soon; and the strong winds usually coming from the west and south-west points, they will be exposed to the fury of them, which frequently is very injurious to them.

Having made choice of a proper situation, you must then proceed to prepare the earth necessary to plant them in; for if the natural soil of the place be very strong or poor, it will be proper to make the border of new earth, removing the former soil away about three feet deep. The best earth for these flowers is a fresh, light, hazel loam, mixed with a little very rotten neats dung: this should be well mixed together, and often turned over, in order to sweeten it; then having removed away the old earth to the fore-mentioned depth, you should put a layer of rotten dung or tan in the bottom, about four or five inches thick, upon which you must lay some of the prepared earth about eighteen or twenty inches thick, making it exactly level; then having marked out by line the exact distances at which the roots are to be planted (which should not be less than six or eight inches square) you must place the roots accordingly, observing to set them upright; then you must cover them over with the before-mentioned earth about eight inches deep, being very careful in doing it, not to displace the roots; when this is done, you must make the surface of the border even, and make up the side strait, which will appear handsome.

The best time for planting these roots is in the end of August, or beginning of September; for if they are kept too long out of the ground, it will cause their flowers to be weak. You should also observe the nature of the soil where they are planted, and whether

ther the situation be wet or dry, according to which you should adapt the fresh earth; and order the beds; for if the soil be very strong and the situation moist, you should then make choice of a light earth, and raise the beds six or eight inches, or a foot, above the level of the ground, otherwise the roots will be in danger of perishing by too much wet; but if the situation be dry and the soil naturally light, you should then allow the earth to be a little stronger, and the beds should not be raised above three or four inches high; for if they are made too high, the roots will suffer very much, if the spring should prove dry, nor would the flowers be near so fair. As also in very severe winters, those beds which are raised much above the level of the ground, will be more exposed to the cold than those which are lower, unless the alleys are filled up with rotten tan or litter.

During the summer, the only culture these flowers require is, to keep them free from weeds; and when their leaves are entirely decayed, they should be raked off, and the beds made clean: but by no means cut off their leaves till they are quite decayed, as is by some practised, for that greatly weakens the roots.

Towards the middle of October, if the weeds have grown upon the beds, you should in a dry day gently hoe the surface of the ground to destroy them, observing to rake it over smooth again; and before the frosts come on, the beds should be covered over two inches thick with rotten tan, to keep out the frost; after which they will require no farther care till the spring, when their leaves will appear above ground; at which time you should gently stir the surface of the earth with a small trowel, being very careful not to injure the leaves of the plants, and rake it smooth with your hands, clearing off all weeds, &c. which, if suffered to remain at that season, will soon grow so fast as to appear unsightly, and will exhaust the nourishment from the earth. With this management these roots will flower very strong, some of which will appear in March, and the others in April; which, if suffered to remain, will continue in beauty a full month, and are, at that season, very great ornaments to a flower-garden.

After the flowers are past, and the leaves decayed, you should stir the surface of the ground, to prevent the weeds from growing; and if at the same time you lay a little very rotten dung over the surface of the beds, the rain will wash down the salts thereof, which will greatly encourage the roots the succeeding year.

During the summer season they will require no farther care, but to keep them clear from weeds till October, when the surface of the beds should be again stirred, raking off all weeds, &c. and laying some good fresh earth over the beds about an inch deep, which will make good the loss sustained by weeding, &c. and in the spring you must manage as was directed for the preceding year.

These roots should not be transplanted oftener than every third year, if they are expected to flower strong and make a great increase; because the first year after removing, they never flower so strong as they do the second and third; nor will the roots increase so fast, when they are often transplanted; but if you let them remain longer than three years unremoved, the number of offsets which by that time will be produced, will weaken the large bulbs, and cause them to produce very weak flowers; therefore at the time of transplanting them, all the small offsets should be taken off, and planted in a nursery-bed by themselves; but the large bulbs may be planted again for flowering. If you plant them in the same bed where they grew before, you must take out all the earth two feet deep, and fill it up again with fresh, in the manner before directed, which will be equal to removing them into another place: this is the constant practice of the gardeners in Holland, who have but little room to change their roots; therefore they every year remove the earth of their beds, and put in fresh, so that the

same place is constantly occupied by the like flowers. But those people take up their roots every year, for as they cultivate them for sale, the rounder their roots are, the more valuable they will be: the way to have them so is, to take their offsets from them annually; for when their roots are left two or three years unremoved, the offsets will have grown large, and these pressing against each other, will cause their sides to be flatted; so that where the roots are propagated for sale, they should be annually taken up as soon as their leaves decay; and the large bulbs may be kept out of the ground till the middle or end of October, but the offsets should be planted the beginning of September or sooner, that they may get strength, so as to become blowing roots the following year: but where they are designed for ornament, they should not be removed oftener than every third year, for then the roots will be in large bunches, and a number of stalks with flowers coming from each bunch, they will make a much better appearance than where a single stalk rises from each root, which will be the case when the roots are annually removed.

The common sorts of Daffodil are generally planted in large borders of the pleasure-garden, where, being intermixed with other bulbous-rooted flowers, they afford an agreeable variety in their seasons of flowering. These roots are very hardy, and will thrive in almost any soil or situation, which renders them very proper for rural gardens, where, being planted under the shade of trees, they will thrive for several years without transplanting, and produce annually in the spring great quantities of flowers, which will make a good appearance before the trees come out in leaf.

The Jonquils should be planted in beds or borders, separate from other roots, because these require to be transplanted at least every year, otherwise their roots are apt to grow long and slender, and seldom flower well after; which is also the case, if they are continued many years in the same soil; wherefore the roots should be often removed from one part of the garden to another, or at least, the earth should be often renewed, which is the most probable method to preserve their flowers in perfection.

The soil in which these flowers succeed best, is an hazel loam, neither too light nor over stiff; it must be fresh, and free from roots of trees or noxious weeds, but should not be dunged; for it is very remarkable, that where the ground is made rich, they seldom continue good very long, but are subject to shoot downwards, and form long slender roots.

These flowers are greatly esteemed by many people for their strong sweet scent, though there be very few ladies that can bear the smell of them; so powerful is it, that many times it overcomes their spirits, especially if confined in a room; for which reason, they should never be planted too close to a habitation, lest they become offensive; nor should the flowers be placed in such rooms where company is entertained.

NASTURTIIUM. See LEPIDIUM.

NASTURTIIUM INDICUM. See TROPÆOLUM.

NATURAL is belonging to, or proceeding from nature.

NATURE is a term variously used; and Mr. Boyle, in a treatise of the vulgarly received notion of Nature, gives us eight principal ones.

1. Nature is used for the system of the world, the machine of the universe, or the assemblage of all created beings.

In this sense we say, the author of Nature, meaning God; and speaking of the sun, call him the father of Nature, because he warms the earth, and makes it fruitful; and the eye of Nature, because he illuminates the universe; and of a phoenix, a unicorn, a griffin, a satyr, that there are no such things in Nature.

2. Nature, in a more confined sense, comprehends the several kinds of beings, created and uncreated, corporeal and spiritual: thus we say, human Nature, i. e. all men who possess the same rational souls; angelical Nature, divine Nature.

3. Nature,

3. Nature, in a still more restrained sense, is used for the essence of a thing, or that attribute that makes a thing what it is; as, it is the Nature of the soul to think.

4. Nature is particularly used for the established order and course of material things, the series of the second causes, or the laws that God has imposed on the motions impressed by him. In this sense we say, the day and night, by Nature, succeed one another; physic is the study of Nature; respiration is by Nature necessary to life.

5. Nature is also used to signify an aggregate of powers, which belong to any body, especially a living one. Thus we say, Nature is strong, Nature is weak, Nature is spent, &c.

6. Nature is also more strictly used for the action of providence, the principle of all things, or that spiritual being which is diffused throughout the creation, and moves and acts in all bodies, and gives them certain properties, and procures certain effects. In this sense, Nature signifies the qualities or virtues that God has given to his creatures, animal, vegetable, &c. In speaking of the action of Nature, no more is to be understood, but that bodies act on one another in a manner agreeable to the general laws of motion which the Creator has established.

NEBULOSE, or NEBULOUS, signifies cloudy, misty, foggy, hazy.

NECTARINE [properly so called of nectar, the poetical drink of the Gods] Nectarine.

This fruit should have been placed under the article of Peaches, to which it properly belongs, differing from them in nothing more than in having a smooth rind, and the flesh being firmer. These the French distinguish by the name of Brugnons, as they do those Peaches which adhere to the stone, by the name of Pavies, retaining the name of Pêche to only such as part from the stone; but since the writers in gardening have distinguished this fruit by the name of Nectarine from the Peaches, so I shall follow their example, lest by endeavouring to rectify their mistakes, I should render myself less intelligible to the reader. I shall therefore mention the several varieties of this fruit, which have come to my knowledge:

1. Fairchild's early Nectarine. This is one of the earliest ripe Nectarines we have; it is a small round fruit, about the size of the Nutmeg Peach, of a beautiful red colour, and well flavoured; it ripens the end of July.

2. Elruge Nectarine: the tree has sawed leaves; the flowers are small; it is a middle-sized fruit, of a dark red or purple colour next the sun, but of a pale yellow or greenish colour towards the wall; it parts from the stone, and has a soft melting juice: this ripens in the beginning of August.

3. Newington Nectarine: the tree has sawed leaves; the flowers are large and open; it is a fair large fruit, (when planted on a good soil) of a beautiful red colour next the sun, but of a bright yellow towards the wall; it has an excellent rich juice; the pulp adheres closely to the stone, where it is of a deep red colour: this ripens the latter end of August, and is the best flavoured of all the sorts, or perhaps of any known fruit in the world.

4. Scarlet Nectarine is somewhat less than the last, of a fine red or scarlet colour next the sun, but loses itself in paler red towards the wall: this ripens in the end of August.

5. Brugnons or Italian Nectarine, has smooth leaves; the flowers are small; it is a fair large fruit, of a deep red colour next the sun, but of a soft yellow towards the wall; the pulp is firm, of a rich flavour, and closely adheres to the stone, where it is very red: this ripens in the end of August.

6. Roman Red Nectarine has smooth leaves, and large flowers; it is a large fair fruit, of a deep red or purple colour towards the sun, but has a yellowish cast next the wall; the flesh is firm, of an excellent flavour, closely adhering to the stone, where it is very red: this ripens in September.

7. Murry Nectarine is a middle sized fruit, of a dirty red colour on the side next the sun, but of a yellowish green towards the wall, the pulp is tolerably well flavoured: this ripens the beginning of September.

8. Golden Nectarine is a fair handsome fruit, of a soft red colour next the sun, but of a bright yellow next the wall; the pulp is very yellow, of a rich flavour, and closely adheres to the stone, where it is of a faint red colour: this ripens the middle of September.

9. Temple's Nectarine is a middle-sized fruit, of a soft red colour next the sun, of a yellowish green toward the wall: the pulp is melting, of a white colour towards the stone, from which it parts, and has a fine poignant flavour; this ripens the end of September.

10. Peterborough, or late green Nectarine, is a middle sized fruit, of a pale green colour on the outside next the sun, but of a whitish green towards the wall; the flesh is firm, and, in a good season, tolerably well flavoured; this ripens the middle of October.

There are some persons who pretend to have more varieties than I have here enumerated, but I much doubt whether they are different, there being so near a resemblance between the fruits of this kind, that it requires a very close attention to distinguish them well, especially if the trees grow in different soils and aspects, which many times alters the same fruit so much, as hardly to be distinguished by persons who are very conversant with them; therefore, in order to be thoroughly acquainted with their differences, it is necessary to consider the shape and size of their leaves, the size of their flowers, their manner of shooting, &c. which is many times very helpful in knowing of these fruits.

The culture of this fruit differing in nothing from that of the Peach, I shall forbear mentioning any thing on that head in this place, to avoid repetition, but only wish those persons who propagate this fruit, will take their buds from bearing trees, and not from young nursery trees, as is too often practised; however, I shall refer the reader to the article PERSICA, where there is an ample account of their planting, pruning, &c.

NEMORAL signifies belonging to a wood or grove.

NEPETA. Lin. Gen. Plant. 629. Cataria. Tourn. Inst. R. H. 202. tab. 95. Catmint, or Nep; in French, Herbes aux Chats.

The CHARACTERS are,

The empalement of the flower is tubulous and cylindrical, indented into five acute parts at the top. The flower is of the lip kind, with one petal, having an incurved cylindrical tube, gaping at the top. The upper lip is erect, roundish, and indented at the point. The under lip is large, concave, entire, and sawed on the edge. It hath four owl-shaped stamina situated under the upper lip, two of which are shorter than the other, terminated by incumbent summits. In the bottom of the tube is situated the quadrifid germen, supporting a slender style, crowned by a bifid acute stigma. The germen afterward turns to four oval seeds, sitting in the empalement.

This genus of plants is ranged in the first section of Linnaeus's fourteenth class, which includes those plants whose flowers have two long and two shorter stamina, and are succeeded by naked seeds sitting in the empalement.

The SPECIES are,

1. NEPETA (Cataria) floribus spicatis, verticillis subpedicellatis, foliis petiolatis cordatis dentato-ferratis. Lin. Sp. Plant. 796. Catmint with spiked flowers, whose whorls have very short foot-stalks, and heart-shaped leaves growing on foot-stalks, which are indented like the teeth of a saw. Cataria major vulgaris. Tourn. Inst. R. H. 202. Common greater Catmint.

2. NEPETA (Minor) floribus spicatis, spicis interruptis, verticillis pedicellatis, foliis subcordatis ferratis petiolatis. Catmint with spikes of flowers, with interrupted whorls standing on foot-stalks, and sawed leaves, with foot-stalks almost heart-shaped. Cataria minor vulgaris.

- garis. Tourn. Inst. R. H. 202. *Smaller common Catmint.*
3. *NEPETA (Angustifolia)* floribus spicatis, verticillis subsessilibus, foliis cordato-oblongis serratis sessilibus. *Catmint with spiked flowers, whose whorls grow almost close to the stalks, and oblong, sawed, heart-shaped leaves, sitting close.* *Cataria angustifolia major.* Tourn. Inst. R. H. 202. *Greater narrow-leaved Catmint.*
4. *NEPETA (Paniculata)* floribus paniculatis, foliis oblongo-cordatis acutis serratis sessilibus. *Catmint with panicled flowers, and oblong, heart-shaped, acute, sawed leaves, sitting close to the stalks.* *Cataria quæ nepeta minor, folio melissæ Turcicæ.* Boerh. Ind. alt. 1. 174. *Smaller Catmint with a Turkey Balm leaf.*
5. *NEPETA (Italica)* floribus sessilibus verticillato-spicatis, bracteis lanceolatis longitudine calycis, foliis petiolatis. Lin. Sp. Plant. 798. *Catmint whose flowers grow in whorled spikes, sitting close to the stalk, having spear-shaped bractæ the length of the empalement, with leaves growing upon the foot-stalks.* *Cataria minor Alpina.* Tourn. Inst. R. H. 202. *Smaller Alpine Catmint.*
6. *NEPETA (Violacea)* verticillis pedunculatis corymbosis, foliis petiolatis cordato-oblongis dentatis. Lin. Sp. Plant. 797. *Catmint with roundish whorls standing upon foot-stalks, and oblong, heart-shaped, indented leaves.* *Cataria Hispanica, betonicæ folio angustiore flore cæruleo.* Tourn. Inst. R. H. 202. *Spanish Catmint with a narrow Betony leaf, and a blue flower.*
7. *NEPETA (Tuberosa)* spicis sessilibus, bracteis ovatis coloratis, foliis summis sessilibus. Hort. Cliff. 311. *Catmint with spiked flowers sitting close to the stalks, oval coloured bractæ, and the upper leaves sitting close to the stalks.* *Cataria Hispanica, supina, betonicæ folio, tuberosâ radice.* Tourn. Inst. R. H. 202. *Spanish Catmint with a declining stalk, a Betony leaf, and a tuberous root.*
8. *NEPETA (Hirsuta)* floribus sessilibus verticillato-spicatis, verticillis tomento obvolutis. Hort. Cliff. 311. *Catmint with flowers growing in whorled spikes sitting close to the stalk, and the whorls covered with down.* *Horminum spicatum lavendulæ flore & odore.* Bocc. Plant. Sic. 48. tab. 25. *Spiked Clary with a Lavender smell and flower.*
9. *NEPETA (Virginica)* foliis lanceolatis, capitulis terminalibus, staminibus flore longioribus. Lin. Sp. Plant. 571. *Catmint with spear-shaped leaves, stalks terminated by flowers growing in heads, and stamina longer than the flower.* *Clinopodium amaraci folio, floribus albis.* Pluk. Alm. 110. *Field Basil with a Marjoram leaf, and a white flower.*
10. *NEPETA (Orientalis)* floribus spicatis, verticillis crassifloribus, foliis cordatis obtusè dentatis petiolatis. *Catmint with spiked flowers, whose whorls are very thick, and heart-shaped leaves which are obtusely indented, and stand upon foot-stalks.* *Cataria Orientalis, teucris folio, lavendulæ odore, verticillis florum crassissimis.* Tourn. Cor. Inst. 13. *Eastern Catmint with a Tree Germander leaf smelling like Lavender, and very thick whorls to the flowers.*
11. *NEPETA (Procumbens)* floribus verticillatis, bracteis ovatis hirsutis, foliis cordato-ovatis crenatis, caule procumbente. *Catmint with whorled flowers, having oval hairy bractæ, oval heart-shaped leaves, which are crenated, and a trailing stalk.*
- The first sort is the common Nep, or Catmint, which grows naturally on the side of banks and hedges in many parts of England; this has a perennial root, from which arise many branching stalks, which are four-cornered, about two feet high, garnished at each joint by two heart-shaped leaves standing opposite, upon pretty long foot-stalks; they are sawed on their edges, and are hoary on their under side. The flowers grow in spikes at the top of the stalks, and below the spikes are two or three whorls of flowers, which have very short foot-stalks. The flowers are white, and have two lips; the upper lip stands erect, and the lower is a little reflexed, and indented at the point; these are each succeeded by four oval black seeds, which ripen in the empalement.

The whole plant has a strong scent between Mint and Penny Royal; it is called Catmint, because the cats are very fond of it, especially when it is withered, for then they will roll themselves on it, and tear it to pieces, chewing it in their mouths with great pleasure. Mr. Ray mentions his having transplanted some of the plants of this sort from the fields, into his garden, which were soon destroyed by the cats, but the plants which came up from seeds in his garden escaped, which verifies the old proverb, viz. "If you set it the cats will eat it, if you sow it the cats will not know it." I have frequently made trial of this, and have always found it true; for I have transplanted one of the plants from another part of the garden, within two feet of some plants which came up from seeds, the latter has remained unhurt, when the former has been torn to pieces and destroyed by the cats; but I have always observed, where there is a large quantity of the herb growing together, they will not meddle with it. This flowers in June and July, and the seeds ripen in autumn. It is used in medicine.

The second sort grows naturally in Italy, and the south of France; the stalks of this are slender, their joints farther asunder, the leaves are narrower, and the whole plant whiter than the first. The spikes of flowers are divided into whorls; the lower of these are two inches apart, others are an inch, and the upper half an inch, and these differences are permanent, for I have always found the seeds produce the same kind.

The stalks of the third sort do not branch so much as either of the former; they are slenderer, and their joints farther asunder; the leaves are small, narrow, and almost heart-shaped, sawed on their edges, hoary, and stand upon short foot-stalks. The spikes of flowers are more broken, or interrupted than those of the second, and the whorls stand upon foot-stalks. It grows naturally in Italy.

The fourth sort grows naturally in Sicily; this rises with a strong four-cornered stalk near three feet high; the lower joints are four or five inches asunder. The leaves are long, narrow, and heart-shaped, deeply sawed on their edges, and set pretty close to the stalk. The flowers grow in panicles along the stalks, and are of a pale purplish colour. It flowers about the same time with the other sorts.

The fifth sort grows naturally upon the Alps; the stalks of this seldom rise more than a foot and a half high, sending out very few branches. The whorls of flowers which form the spike, are distant from each other, and set close to the stalk. The leaves are short, oval, heart-shaped, and stand upon foot-stalks; the plant is hoary, and strong scented.

The sixth sort grows naturally in Spain; the stalks of this rise about two feet high, and have a few slender branches coming out from the sides. The leaves are heart-shaped, and indented on their edges. The flowers grow in roundish whorls, upon foot-stalks, and are blue; there is also a variety of this with white flowers.

The seventh sort grows naturally in Portugal; this has a thick knobbed root, from which comes out one or two stalks, which often decline to the ground; they are about two feet and a half long, and send out two side branches opposite. The leaves are oblong, crenated on their edges, and sit close to the stalks, and are of a deep green. The upper part of the stalk, for more than a foot in length, is garnished with whorls of flowers, the lower being two inches asunder, but are nearer all the way upward; these sit very close to the stalks, and are guarded by oval, small, coloured leaves, or bractæ. The flowers are blue, and shaped like those of the other species; there is one of this sort with an erect stalk, which is the only difference between them.

The eighth sort grows naturally in Sicily. The stalks of this grow about two feet high; the branches come out toward the bottom; they are heart-shaped, obtuse, and but little indented, standing upon pretty

long foot-stalks. The stalks are terminated by long spikes of whorled flowers, which are separated, and sit close to them; these are wrapped in a hoary down. The flowers are white, and appear in July.

The ninth sort grows naturally in North America; this hath a perennial root, from which arise several four-cornered stalks two feet high, which are garnished with hairy leaves, somewhat like those of Marjoram, but are larger. The flowers grow in whorls round the stalks, and also at the extremity of the stalk, in a large roundish whorl or head; they are of a pale flesh colour, and their stamina is longer than the petal. It flowers in July.

The tenth sort grows naturally in the Levant, from whence the seeds were sent to Paris, by Dr. Tournefort. The stalks of this are strong, and rise near three feet high. The leaves are heart-shaped, and have blunt indentures on their edges, standing upon short foot-stalks. The flowers grow in whorled spikes at the top of the stalks; the whorls are very thick, and set close together, terminating in an obtuse point. The flowers are of a pale flesh colour; the whole plant is hoary, and has a strong scent.

The eleventh sort grows naturally among the rocks in Candia, where it is used as Water Germander by the inhabitants; this hath four-cornered stalks a foot long, which trail upon the ground, sending out some slender branches from the side. The leaves are very like those of the round-leaved Mentastrum, sitting close to the stalk. The flowers grow in thick roundish whorls, which sit close to the stalk, and are surrounded by oval hairy leaves, or bractea. The flowers are white, and just peep out of their empalements. The roots of this sort seldom continue longer than two years, but as the seeds ripen well, so if they are permitted to scatter, the plants will come up the following spring.

All the sorts are very hardy, so are not injured by frost: they are easily propagated by seeds, for if they are permitted to fall, the plants will rise without trouble; or if the seeds are sown, either in the spring or autumn, the plants will come up, and require no other culture but to thin them where they are too close, and keep them clean from weeds. If these plants are sown upon a poor dry soil, they will not grow too rank, but will continue much longer, and appear handsomer than in rich ground, where they grow too luxuriant, and have not so strong a scent.

NERIUM. Lin. Gen. Plant. 262. Nerion. Tourn. Inst. R. H. 604. tab. 374. The Oleander, or Rose Bay; in French, *Laurier Rose*.

The CHARACTERS are,

The empalement of the flower is permanent, and cut into five acute segments. The flower has one funnel-shaped petal. The tube is cylindrical; the border is large, and cut into five broad obtuse segments, which are oblique. It hath a nectarium terminating the tube, which are torn into hairy segments. It hath five short awl-shaped stamina within the tube, with arrow-pointed summits joining together, terminated by a long thread. It hath an oblong germen, which is bifid, with scarce any style, crowned by single stigmas. The germen afterward turns to two long, taper, acute-pointed pods, filled with oblong seeds, lying over each other like the scales of fish, and crowned with down.

This genus of plants is ranged in the first section of Linnæus's fifth class, which contains those plants whose flowers have five stamina and one style.

The SPECIES are,

1. **NERIUM** (*Oleander*) foliis linearilanceolatis ternis. Hort. Cliff. 76. *Oleander, or Rose Bay, with linear spear-shaped leaves, which are placed by threes round the stalk.* Nerion floribus rubescentibus. C. B. P. 464. *Oleander with red flowers.*
2. **NERIUM** (*Indicum*) foliis linearibus rigidis. *Oleander, or Rose Bay, with linear rigid leaves.* Nerium Indicum, angustifolium, floribus odoratis simplicibus.

H. L. Narrow-leaved Indian Rose Bay, with single sweet-scented flowers.

3. **NERIUM** (*Latifolium*) foliis lanceolatis longioribus flaccidis. *Rose Bay with longer, spear-shaped, flaccid leaves.* Nerium Indicum latifolium, floribus odoratis plenis. H. L. *Broad-leaved Indian Rose Bay with double sweet flowers, commonly called the double Oleander.*

The first sort grows naturally in Greece, and in several countries near the Mediterranean sea, generally by the sides of rivers and brooks: there are two varieties of this; one with white, the other with red flowers, but seem to have no other difference, so may properly be placed together as one species, though that with white flowers is rarely found growing wild in any place but the island of Crete.

These rise with several stalks to the height of eight or ten feet. The branches come out by threes round the principal stalks, and have a smooth bark, which in the red flowering is of a purplish colour, but the white sort hath a light green bark. The leaves for the most part stand by threes round the stalks, upon very short foot-stalks, and point upward; they are about three or four inches long, and three quarters of an inch broad in the middle, of a dark green, very stiff, and end in acute points. The flowers come out at the end of the branches, in large loose bunches, which are in one of a bright purple, or crimson colour, and in the other they are of a dirty white; they have short tubes, and spread open at the top, where they are deeply cut into five obtuse segments, which are twisted at bottom, so are oblique to the tube. At the mouth of the tube, the torn capillary nectarium is situated, and within the tube are the five stamina, with the germen at bottom, which afterward turns to a brown, taper, double pod, about four inches long, which opens longitudinally on one side, and is filled with oblong seeds, crowned with long hairy down, lying over each other like the scales of fish. This plant flowers in July and August, and in warm seasons they are succeeded by pods, but the seeds seldom ripen well here.

When the summers are warm and dry, these plants make a fine appearance, for then they open and flower in great plenty; but, in cold moist seasons, the flowers often decay without expanding, and the sort with white flowers is more tender than the red; so that unless the weather is warm and dry at the time the flowers appear, they rot, and make no figure, unless they are placed under glasses to screen them.

The second sort grows naturally in India; this rises with shrubby stalks six or seven feet high, which are covered with a brown bark, and garnished with stiff leaves from three to four inches long, and not more than a quarter of an inch broad; they are of a light green, and their edges are reflexed; these are placed sometimes opposite, at others they are alternate, and sometimes by threes round the branches. The flowers are produced in loose bunches at the end of the branches; they are of a pale red, and have an agreeable musky scent. It flowers at the same time with the former, but these flowers seldom open here in the open air, so that unless the plants are placed in an airy glass-case, where they are defended from wet and cold, they seldom flower well.

The third sort grows naturally in both Indies; this plant was first introduced to the British Islands in America, from the Spanish Main, and is called by the inhabitants of those islands South Sea Rose; the beauty and sweetness of its flowers engaged the inhabitants of the islands to cultivate the plants, so that in many places they were planted to form hedges; but the cattle browsing upon them, when there was scarcity of food, were many of them killed, which has occasioned their being destroyed in places exposed to cattle; so that now they are only preserved in gardens, where they make a fine appearance great part of the year, for in those warm countries they are seldom

dom destitute of flowers. This has been by some persons, who have only a superficial knowledge of plants, thought only a variety of the common sort, but those who have cultivated both, know better; for the first will live through the winter in the open air, in a warm situation, but this is too tender to thrive in England, unless preserved in a warm green-house; nor will the plants flower without the assistance of a glass-case in summer. The third sort was not known here till the beginning of last century, being a stranger in Europe, but the former has been in the English gardens near two centuries: nor has the seeds of the first ever produced plants of the third sort, though this has been positively asserted by persons of no skill.

The leaves of this sort are six inches long, and one inch broad in the middle, of a much thinner texture than those of the first, and their ends are generally reflexed; they are of a light green, and irregularly placed on the branches; sometimes they are by pairs, at others alternate, and sometimes by threes round the branches. The flowers are produced in very large bunches at the end of the branches, standing upon long foot-stalks; they have three or four series of petals within each other, so are more or less double. The flowers are much larger than those of the common sort, and smell like the flowers of Hawthorn. The plain flowers are of a soft red, or Peach colour; but in most they are beautifully variegated with a deeper red, and make a fine appearance. Their usual time of flowering is in July and August, but if they are placed in a warm stove, they will continue in flower till Michaelmas. As the flowers of this are double, they are not succeeded by seeds; and at present we are unacquainted with the single flowering of this kind, for the second is undoubtedly a distinct species.

All the species of the Rose Bay are supposed to have a poisonous quality; the young branches, when cut or broken, have a milky sap or juice, and the larger branches, when burnt, emit a very disagreeable odour, so there is great reason to believe the plants have some noxious quality; but this genus of plants has been confounded by many of the writers on botany with the *Chamaerhododendros* of Tournefort, and many of the noxious qualities with which the latter abounds, have been applied to the *Nerium*, but particularly that of the honey, about Trebisond, which is reckoned very unwholesome, which has been supposed to be occasioned by the bees sucking it from the flowers of the *Nerium*; whereas it is from the flowers of the *Chamaerhododendros*, as Tournefort has fully informed us; but the affinity of their names in the Greek language has occasioned these two plants to be often confounded.

These plants are generally propagated by layers in this country, for although they will sometimes take root from cuttings, yet that being an uncertain method, the other is generally pursued; and as the plants are very apt to produce suckers, or shoots from their roots, those are best adapted for laying, for the old branches will not put out roots; when these are laid down, they should be slit at a joint, in the same manner as is practised in laying of Carnations, which will greatly facilitate their taking root: if these branches are laid down in autumn, and are properly supplied with water, they will have taken root by that time twelvemonth, when they should be carefully raised up with a trowel; and if they have taken good root, they should be cut off from the old plant, and each planted in a separate small pot, filled with soft loamy earth; those of the common sort will require no other care, but to be placed in a shady situation, and gently watered as the season may require, till they have taken new root; but the two other species should be plunged into a very moderate hot-bed, to forward their taking root, observing to shade them from the sun in the heat of the day; after the common sort has taken new root, the plants may be placed in a sheltered situation with other hardy exo-

tics, where they may remain till the end of October, when they should either be removed into the green-house, or placed under a hot-bed frame; where they may be protected from frost in winter, but enjoy the free air at all times when the weather is mild.

This sort is so hardy as to live abroad in mild winters, if planted in a warm situation; but as they are liable to be destroyed in severe frost, the best way is to keep the plants in pots, or if they are very large in tubs; that they be sheltered in winter, and in the summer removed abroad, placing them in a warm sheltered situation. In the winter they may be placed with Myrtles, and other of the hardier kinds of exotic plants, in a place where they may have as much free air as possible in mild weather, but screened from severe frost; for if these are kept too warm in winter, they will not flower strong, and when the air is excluded from them, the ends of their shoots will become mouldy; so that the hardier they are treated, provided they are not exposed to hard frosts, the better they will thrive.

The other two sorts require a different treatment, otherwise they will not make any appearance; therefore the young plants when they have taken new root, should be gradually inured to bear the open air, into which they should be removed in July, where they may remain till October, provided the weather continues mild; but during this time, they should be placed in a sheltered situation; and upon the first approach of frost, they should be removed into shelter, for if their leaves are injured by frost, they will change to a pale yellow, and will not recover their usual colour till the following autumn. These sorts may be preserved in a good green-house through the winter, and the plants will be stronger than those which are more tenderly treated; but in May, when the flower-buds begin to appear, the plants should be placed in an open glass-case, where they may be defended from the inclemency of the weather; but when it is warm weather, the air should at all times be admitted to them in plenty. With this management the flowers will expand, and continue long in beauty; and during that time, there are few plants which are equal to them, either to the eye or nose, for their scent is very like that of the flowers of the White Thorn; and the bunches of flowers will be very large, if the plants are strong.

NERVES are long tough strings, which run either across, or lengthways, in the leaves of plants.

NICOTIANA. Tourn. Inst. R. H. 117. tab. 41. Lin. Gen. Plant. 220. [This plant takes its name from James Nicotius, counsellor to Francis II. King of France, who in the year 1560, being ambassador to the court of Portugal, bought the seeds of this plant of a Dutchman, who brought them from America, and sent them to Queen Catharine de Medicis in France; where, being sown, they produced seeds: the Indian inhabitants call it Tabac, because it grew in an island called Tabaco, or Tobago. The lesser sort is by some called Hyoscyamus, because it agrees in some of its characters with this plant; it is also called Priapeia.] Tobacco; in French, *Nicotiane ou Tabac*.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, cut into five acute segments. The flower has one funnel-shaped petal, with a long tub spread open at the brim, and ending in five acute points. It hath five awl-shaped stamina which are the length of the tube; a little inclined, and terminated by oblong summits; and an oval germen supporting a slender style, crowned by an indented stigma. The germen afterward turns to an oval capsule, with a furrow on each side, having two cells which open at the top, and are filled with rough seeds fastened to the partition.

This genus of plants is ranged in the first section of Linnaeus's fifth class, which contains those plants whose flowers have five stamina and one style.

The

The SPECIES are,

1. NICOTIANA (*Latissima*) foliis ovato-lanceolatis rugosis, semiamplexicaulibus. Tobacco with oval, spear-shaped, rough leaves, which half embrace the stalks. Hyoscyamus Peruvianus. Ger. 357. Tobacco, or Henbane of Peru.
2. NICOTIANA (*Tabacum*) foliis lanceolato-ovatis decurrentibus, floribus acutis. Lin. Sp. Plant. 258. Tobacco with oval, spear-shaped, running leaves, sitting close to the stalks. Nicotiana major latifolia. C. B. P. 169. Greater broad-leaved Tobacco.
3. NICOTIANA (*Angustifolia*) foliis lanceolatis acutis, sessilibus, calycibus acutis, tubo floris longissimo. Plat. 185. Tobacco with acute spear-shaped leaves sitting close to the stalks, sharp-pointed empalements, and a very long tube to the flower. Nicotiana major angustifolia. C. B. P. 170. Greater narrow-leaved Tobacco.
4. NICOTIANA (*Fruticosa*) foliis lineari-lanceolatis acuminatis semiamplexicaulibus, caule fruticoso. Tobacco with linear, spear-shaped, acute-pointed leaves, half embracing the stalks, and a shrubby stalk. Nicotiana major angustissimo folio perennis. Juss. Narrowest-leaved, greater, perennial Tobacco.
5. NICOTIANA (*Alba*) foliis ovatis acuminatis semiamplexicaulibus, capsulis ovatis obtusis. Tobacco with oval acute-pointed leaves half embracing the stalk, and oval obtuse seed-vessels. Nicotiana major latifolia, floribus albis, vasculo brevi. Martyn. Dec. 5. Greater broad-leaved Tobacco with white flowers, and a short seed-vessel.
6. NICOTIANA (*Rustica*) foliis petiolatis ovatis integerrimis, floribus obtusis. Lin. Sp. 258. Tobacco with oval entire leaves, and obtuse flowers. Nicotiana minor. C. B. P. 170. Smaller Tobacco, commonly called English Tobacco.
7. NICOTIANA (*Rugosa*) foliis ovatis rugosis petiolatis. Tobacco with oval rough leaves, having foot-stalks. Nicotiana minor, foliis rugosioribus amplioribus. Vaill. Smaller Tobacco with larger and rougher leaves.
8. NICOTIANA (*Paniculata*) foliis petiolatis cordatis integerrimis, floribus paniculatis obtusis clavatis. Lin. Sp. Plant. 259. Tobacco with heart-shaped leaves, paniculated flowers, and club-shaped tubes. Nicotiana minor, folio cordiformi tubo floris prælongis. Feuille. Obs. 1. p. 717. tab. 10. Smaller Tobacco with a heart-shaped leaf, and a very long tube to the flower.
9. NICOTIANA (*Glutinosa*) foliis petiolatis cordatis integerrimis, racemosis floribus secundis ringentibus, calycibus inæqualibus. Lin. Sp. Plant. 259. Tobacco with heart-shaped leaves, having foot-stalks, branching ringent petals, and unequal empalements.
10. NICOTIANA (*Humilis*) foliis ovato-lanceolatis obtusis rugosis, calycibus brevissimis. Plat. 185. Tobacco with oval, spear-shaped, obtuse, rough leaves, and a very short empalement. Nicotiana humilis, primulæ veris folio. Hoult. MSS. Dwarf Tobacco with a Primrose leaf.

The first sort was formerly the most common Tobacco which was sown in England, and which has been generally taken for the common broad-leaved Tobacco of Caspar Bauhin, and others, but is greatly different from it. The leaves of this sort are more than a foot and a half long, and a foot broad, their surfaces very rough and glutinous: when these plants are in a rich moist soil, they will grow more than ten feet high; the base of the leaves half embrace the stalks; the upper part of the stalk divides into smaller branches, which are terminated by loose bunches of flowers standing erect; they have pretty long tubes, and are of a pale purplish colour. It flowers in July and August, and the seeds ripen in the autumn. This is the sort of Tobacco which is commonly brought to the markets in pots to adorn the shops and balconies of London, and by some is called Oroonoko Tobacco.

The second sort is the broad-leaved Tobacco of Caspar Bauhin; the stalks of this seldom rise more than five or six feet high, and divide into more branches than the first. The leaves are about ten inches long, and three and a half broad, smooth, and end in acute

points, sitting close to the stalks; the flowers of this are rather larger, and of a brighter purple colour than those of the first. It flowers and perfects seeds at the same time; this is by some called sweet-scented Tobacco.

The third sort rises with an upright branching stalk four or five feet high; the lower leaves are a foot long, and three or four inches broad; those on the stalks are much narrower, lessening to the top, and end in very acute points, sitting close to the stalks; they are very glutinous. The flowers grow in loose bunches at the top of the stalks, they have long tubes, and are of a bright purple or red colour. These appear at the same time with the former sorts, and their seeds ripen in the autumn.

The fourth sort rises with very branching stalks about five feet high; the leaves on the lower part of the stalks are a foot and a half long, broad at the base, where they half embrace the stalks, and are about three inches broad in the middle, terminating in long acute points; the stalks divide into many smaller branches, which are terminated by loose bunches of flowers, of a bright purple colour, and are succeeded by acute-pointed seed-vessels. This flowers about the same time with the former, but if the plants are placed in a warm green-house, they will live through the winter. The seeds of this sort were sent me for Brazil Tobacco.

The fifth sort grows naturally in the woods in the island of Tobago, from whence the seeds were sent me by the late Mr. Robert Millar. This rises about five feet high; the stalk does not branch so much as those of the former; the leaves are large and oval, about fifteen inches long and two broad in the middle, but diminish gradually in their size to the top of the stalk, and with their base half embrace it. The flowers grow in closer bunches than those of the former, and are white; these are succeeded by short, oval, obtuse seed-vessels. It flowers and perfects seeds about the same time with the former.

The sixth sort is commonly called English Tobacco, from its having been the first which was introduced here, and being much more hardy than the other sorts. The seeds ripen very freely, and scattering in the autumn, the plants have come up without care, wherever any of the plants have been suffered to run to seed, so that it has been a weed in many places; but it came originally from America, by the title of Petum. Dodonæus, Tabernemontanus, and others, have titled it Hyoscyamus luteus, from the affinity there is between this plant and the Henbane; but the flowers of this are tubulous, and not ringent, as are those of the Henbane; nor do the seed-vessels of this open with a lid on the top, as that of Henbane. The stalks of this seldom rise more than three feet high; the leaves are placed alternately on the stalks, standing upon short foot-stalks; they are oval and smooth. The flowers grow in small loose bunches on the top of the stalks; they have short tubes, which spread open at the top, and are cut into five obtuse segments, of an herbaceous yellow colour, appearing in July, and are succeeded by roundish capsules, filled with small seeds, which ripen in the autumn.

The seventh sort rises with a strong stalk near four feet high; the leaves of this are shaped like those of the former, but are greatly furrowed on their surface and near twice the size, of a darker green, and have longer foot-stalks. The flowers are larger than those of the former, and of the same shape. This is undoubtedly a distinct plant from the former, for I have sown the seeds more than thirty years, and have never found any of the plants vary.

The eighth sort was found growing naturally in the valley of Lima, by Pere Feuille, in the year 1710; and of late years the seeds of it were sent from Peru, by the younger de Jussieu, to Paris. The stalk of this sort rises more than three feet high, dividing upward into many smaller panicled branches, which are round and a little hairy; the leaves are heart-shaped, about four inches long, and three broad, standing upon

upon pretty long foot-stalks. The flowers are produced in loose panicles at the end of the branches; these have tubes about an inch long, shaped like a club; the brim is slightly cut into nine obtuse segments, which are reflexed; they are of a yellowish green colour, and are succeeded by roundish capsules, filled with very small seeds. The flowers about the same time with the other sorts.

The seeds of the ninth sort were sent from Peru with those of the former, by the younger de Jussieu; the stalk of this is round, and rises near four feet high, sending out two or three branches from the lower part; the leaves are large, heart-shaped, and a little waved; they are very clammy, standing upon long foot-stalks. The flowers grow in loose spikes at the top of the stalk, having short open tubes, which are curved almost like the lip flowers; they are of a dull purple colour; the empalement is unequally cut, one of the segments being twice the size of the other.

The tenth sort was discovered by the late Dr. Houttoun at La Vera Cruz, who sent the seeds to England. This hath a pretty thick taper root, which strikes deep in the ground; at the top comes out six or seven oval spear-shaped leaves, which spread on the surface of the ground; they are about the size of those of the common Primrose, but are of a deeper green; the stalk rises about a foot high, branching into three or four divisions, at each of these is placed one small leaf; the branches are terminated by a loose spike of flowers, which are small, tubulous, and of a yellowish green colour, having very short empalements, which are cut at the brim into five acute segments. The seed-vessel is small, oval, and divided into two cells, which are full of small seeds.

All the sorts except the sixth, seventh, and eighth, require the same culture, and are too tender to grow from seeds sown in the full ground, to any degree of perfection in this country, so require to be raised in a hot-bed, after the following manner:

The seeds must be sown upon a moderate hot-bed in March, and when the plants are come up fit to remove, they should be transplanted into a new hot-bed of a moderate warmth, about four inches asunder each way, observing to water and shade them until they have taken root; after which you must let them have air in proportion to the warmth of the season, otherwise they will draw up very weak, and be thereby less capable of enduring the open air: you must also observe to water them frequently, but while they are very young, it should not be given to them in too great quantities; though when they are pretty strong, they will require to have it often, and in plenty.

In this bed the plants should remain until the middle of May, by which time (if they have succeeded well) they will touch each other, therefore they should be inured to bear the open air gradually; after which they must be taken up carefully, preserving a large ball of earth to each root, and planted into a rich light soil, in rows four feet asunder, and the plants three feet distance in the rows, observing to water them until they have taken root; after which they will require no farther care (but only to keep them clean from weeds) until the plants begin to shew their flower-stems; at which time you should cut off the tops of them, that their leaves may be the better nourished, whereby they will be rendered larger, and of a thicker substance. In August they will be full grown, when they should be cut for use; for if they are permitted to stand longer, their under leaves will begin to decay. This is to be understood for such plants as are propagated for use, but those plants which are designed for ornament, should be planted in the borders of the pleasure-garden, and permitted to grow their full height, where they will continue flowering from July, till the frost puts a stop to them.

The three smaller sorts of Tobacco are preserved in botanic gardens for variety, but are seldom propagated for use. The first sort is found growing upon dunghills in divers parts of England. The sixth and

seventh are very hardy, and may be propagated by sowing their seeds in March, upon a bed of light earth, where they will come up, and may be transplanted into any part of the garden, where they will thrive without farther care.

The last sort being somewhat tenderer than the other, should be sown early in the spring on a hot-bed; and when the plants come up, they should be transplanted on another moderate hot-bed, where they must be duly watered, and should have a large share of free air in warm weather; and when the plants have obtained a good share of strength, they should be transplanted into separate pots, and plunged into a moderate hot-bed to bring them forward. About the middle of June some of the plants may be shaken out of the pots, and planted into beds of rich earth; but it will be proper to keep one or two plants in pots, which may be placed in the stove (in case the season should prove bad,) that they may ripen their seeds, so that the species may be preserved.

NIGELLA. Tourn. Inst. R. H. 258. tab. 134. Lin. Gen. Plant. 606. [so called, as though Nigrella, from the colour of its seed, because the seeds of this plant are, for the most part, black. It is also called Melianthum, of μέλας, black, and ἀνθος, a flower, q. d. black flower, although the flower is not black: it is also called Melaspermum, of μέλας, black, and σπέρμα, seed.] Fennel-flower, or Devil in a bush.

The CHARACTERS are,

The flower has no empalement, but a leafy perianthium. It hath five oval, obtuse, plain petals, which spread open, and are contracted at their base, and eight very short nectariums situated in a circle, each having two lips; the exterior being larger, the inferior bifid, plain, and convex; the interior is shorter, narrower, from an oval terminating in a line. It hath a great number of awl-shaped stamina, which are shorter than the petals, terminated by obtuse, compressed, erect summits; and in some five, in others ten, oblong, convex, erect germen, ending in awl-shaped styles, which are long, revolved, and permanent, having stigmas fastened longitudinally to them. The germen afterward become so many oblong compressed capsules, divided by a furrow, but connected within, filled with rough angular seeds.

This genus of plants is ranged in the fifth section of Linnæus's thirteenth class, which includes those plants whose flowers have many stamina and five styles.

The SPECIES are,

1. **NIGELLA** (*Arvensis*) pistillis quinis, petalis integris, capsulis turbinatis. Lin. Sp. Plant. 534. *Fennel-flower having five pointals, entire petals, and turbinated seed-vessels.* Nigella arvensis cornuta. C. B. P. *Field horned Fennel-flower.*
2. **NIGELLA** (*Damascena*) floribus involucro folioso cinctis. Hort. Cliff. 215. *Fennel-flower whose flowers are encompassed with a leafy involucre.* Nigella angustifolia, flore majore simplici cæruleo. C. B. P. 145. *Narrow-leaved Fennel-flower, having a larger, single, blue flower.*
3. **NIGELLA** (*Sativa*) pistillis quinis, capsulis muricatis subrotundis, foliis subpilosis. Hort. Upsal. 154. *Fennel-flower with five pointals which are prickly, and leaves somewhat hairy.* Nigella flore minore simplici candido. C. B. P. 145. *Fennel-flower with a smaller, single, white flower.*
4. **NIGELLA** (*Cretica*) pistillis quinis, corolla longioribus, petalis integris. *Fennel-flower with five pointals longer than the petals, which are entire.* Nigella Cretica latifolia odorata. Park. Theat. 1376. *Broad-leaved sweet-smelling Fennel-flower of Crete.*
5. **NIGELLA** (*Latifolia*) pistillis denis corolla brevioribus. *Fennel-flower with ten pointals which are shorter than the petals.* Nigella alba simplici flore. Alp. Exot. 261. *Fennel-flower with a single white flower.*
6. **NIGELLA** (*Hispanica*) pistillis denis corollam æquantibus. Hort. Upsal. 154. *Fennel-flower with ten pointals equalling the petal.* Nigella latifolia flore majore simplici cæruleo. C. B. P. 145. *Broad-leaved Fennel-flower with a large, single, blue flower.*

7. *Nigella (Orientalis)* pistillis dens corollâ longioribus. Hort. Cliff. 215. *Fennel-flower with ten pointals which are longer than the petals.* *Nigella Orientalis,* flore flavescente, semine alato plano. Tourn. Cor. 19. *Fennel-flower of the East, with a yellowish flower, and a plain winged seed.*

The first sort grows naturally among the Corn, in France, Italy, and Germany, so is seldom propagated in gardens; this rises with slender stalks near a foot high, which sometimes branch out at the bottom, and at others they are single, garnished with a few very fine cut leaves, somewhat like those of Dill; each stalk is terminated by one star-pointed flower of five petals, which are of a pale blue colour, and have no leafy involucre under them; these are succeeded by capsules, having five short horns, which incline different ways at the top, and are filled with rough black seeds; there is a variety of this with white flowers, and another with double flowers.

The second sort grows naturally in Spain and Italy, among the Corn; this rises with an upright branching stalk a foot and a half high, garnished with leaves much longer and finer than those of the first. The flowers are large, of a pale blue, and have a long leafy involucre under each: these are succeeded by larger swelling seed-vessels, with horns at the top; of this there is one with single white flowers, and another with double flowers, which is sown in gardens for ornament.

The third sort grows naturally in Crete; this rises about the same height as the former. The leaves are not so finely cut as those of the second, and are a little hairy. At the top of each stalk is one flower, composed of five white petals, which are slightly cut at their end into three points; these are succeeded by oblong swelling seed-vessels, with five horns at the top, filled with small pale-coloured seeds.

The fourth sort grows naturally in Crete; this rises with branching stalks about a foot high, garnished with shorter and broader leaves than either of the other species. At the top of each branch is one flower, having no involucre; they are composed of five oval petals, and have five pointals longer than the petals; the seed-vessel is not much swollen, and has five slender horns at the top; the seeds are of a light yellowish brown colour.

The fifth sort is also a native of Crete; this rises with a branching stalk a foot high, garnished with leaves like those of Larkspur. The flowers have five large oval petals, which are entire, and ten pointals which are shorter than the petals, and a great number of green stamina with blue chives; the seed-vessels are like those of the last sort.

The sixth sort rises a foot and a half high; the lower leaves are finely cut, but those on the stalks are cut into broader segments. The flowers are larger than those of the other species, and are of a fine blue colour: the pointals of this are of equal length with the petals; the seed-vessel has five horns, and is of a firmer texture than any of the other. This grows naturally in the south of France and Spain; there is a variety of this with double flowers.

The seventh sort grows naturally in the Corn-fields about Aleppo; this rises with a branching stalk a foot and a half high, garnished with pretty long leaves, which are finely divided. The flowers are produced at the end of the branches; they are composed of five yellowish leaves or petals; at the base of these are placed eight nectariums, between which arise a great number of stamina, with an unequal number of germs, some having but five, others have eight or nine; they are oblong and compressed; these afterward become so many oblong compressed seed-vessels, joined together on their inner side, terminating with horns, and open longitudinally, containing many thin compressed seeds, having borders round them.

The varieties of these with double flowers, are chiefly propagated in gardens for ornament; but those with single flowers are rarely admitted into any but botanic

gardens, where they are preserved for the sake of variety.

All these plants may be propagated by sowing their seeds upon a bed of light earth, where they are to remain (for they seldom succeed well if transplanted;) therefore, in order to have them intermixed amongst other annual flowers in the borders of the flower-garden, the seeds should be sown in patches at proper distances; and when the plants come up, you must pull up those which grow too close, leaving but three or four of them in each patch, observing also to keep them clear from weeds, which is all the culture they require. In July they will produce their flowers, and their seeds will ripen in August, when they should be gathered and dried; then rub out each sort separately, and preserve them in a dry place.

The season for sowing these seeds is in March; but if you sow some of them in August, soon after they are ripe, upon a dry soil and in a warm situation, they will abide through the winter, and flower strong the succeeding year; so by sowing the seeds at different times, they may be continued in beauty most part of the summer.

They are all annual plants, which perish soon after they have perfected their seeds; which, if permitted to scatter upon the borders, will come up without any farther care.

NITRE is a kind of salt, impregnated with abundance of spirits out of the air, which renders it volatile.

Monsieur LeClerc gives us the following account of it: In Egypt they make a great quantity of it, but it is not so good, for it is dusky, and full of knots and stones.

It is made almost in the manner that salt is made, but only that they use sea-water in their salt-works, and the water of Nile about their Nitre.

When the Nile retires, their Nitre-pits stand soaking for forty days together; but as the Nitre is grown firm, they are in haste to carry it off, lest it should melt again in the pits. They pile it up in heaps, and it keeps very well.

The Memphian Nitre grows strong, and there are several pits of stone thereabouts; out of these they make vessels, and some they melt down with sulphur among their coals.

This same Nitre they use also about such things as they would have to last a long time.

The proof of the goodness of Nitre is, that it be very light, very friable, and very near of a purple colour. There is but very little difference between the natural and artificial Nitre; but that the one refines itself, and the other is refined by art, as salt; and, indeed, all Nitre is a kind of salt, and hardly differs from salt, properly so called, farther than in these respects. That well refined Nitre is more acid and light than salt, and easily takes fire.

The reason of which difference, he says, seems to be;

1. That the angles at both ends of the oblong particles of Nitre are shorter than the angles of the saline particles.

2. That the particles of Nitre are finer and fuller of pores; which, when the particles of fire get in, they soon put the nitrous particles into a hurry, till they break to pieces, and turn to flame.

3. Nitre exceeds salt in lightness, because the saline particles contain more homogeneous matter in the same compass, than the nitrous do.

Dr. Lister tells us, he viewed the particles of Nitre through a microscope, and found them to have six angles, parallelogram sides, and pointed like a pyramid at one end.

N O L

Some authors are of opinion, that the nitrous salts seem to be assigned by nature chiefly for the growth of plants.

Others differ from them in opinion, and say, that when Nitre is contiguous to plants, it rather destroys than nourishes them; but yet they allow, that Nitre and other salts do certainly loosen the earth, and separate the concreted parts of it, and by that means, fit and dispose them to be assumed by water, and carried up into the seed or plant, for its formation and augment.

It is observable, how all salts are wrought upon by moisture, how easily they liquidate and run with it; and when these are drawn off, and have deserted the lumps wherewith they were incorporated, those must moulder immediately, and fall asunder of course.

The hardest stone, if it has any salt mixed with the sand of which it consists, upon being exposed to a humid air, in a short time dissolves and crumbles all to pieces; and much more will clodded earth and clay, which is not of near so compact and solid a constitution as stone is.

If the earth be never so good and fit for the production of vegetables, little will come of it, unless the parts of it be separated and loose; and for this reason, is the ground digged, ploughed, and harrowed, and the clods broken; and it is this way that Nitre, sea-salt, and other salts, promote vegetation.

A certain gentleman has given a relation, That he dwelling in the country near a petre-house, where such saltpetre as is brought from abroad, is boiled and refined, to make gunpowder, this being so near as to communicate the steam of the Nitre to the greatest part of the orchard and garden; and, though some were of opinion that it injured his trees and plants, yet he found, that it had a contrary influence upon his orchard, &c. in that it never failed to bring him a plentiful crop of fruit every year, although those about him had but very little, or scarce any; notwithstanding his orchard, &c. was not less exposed to blighting winds by its natural situation, than the other orchards in the same town. From whence he judged, that the nitrous vapour which mixes with the air that surrounds his orchard, prevents blights, and is noxious to the caterpillars.

The Lord Bacon, in his Natural History, commends the use of Nitre, for the preservation of health in human bodies; and many skilful husbandmen have given it no less a character for the preservation of vegetables, if its quantity be rightly proportioned.

That the atmosphere does abound with saline particles, is most certain; for being filled continually with effluvia from earth and sea, it must needs have from both a great quantity of saline corpuscles; and the salt will be of different kinds, according to the variety of those salts from whence they are derived.

NOLANA. Royen. Lin. Gen. Plant. 193.

The CHARACTERS are,

The empalement of the flower is of one leaf, turbinated at the base, divided into five acute heart-shaped segments, and is permanent. The flower is bell-shaped, plaited, spread open, and is twice as large as the empalement; it hath five oval-shaped erect stamina, which are terminated by arrow-pointed summits, and five roundish germen surrounding a cylindrical erect style, crowned by a beaded stigma. The succulent interior base of the receptacle becomes four cells, in which the seeds are inclosed.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes the plants having five stamina and one style.

We know but one SPECIES of this genus at present viz.

NOLANA (*Prostrata*.) Lin. Sp. 202. Dec. 1. tab. 2. *Trailing Nolana. Atropa foliis geminatis, calycibus polycarpis, caule humifusa. Gouan. Monsp. 82. Deadly Nightshade with two leaves at each joint, flower-cups with several seeds, and a trailing stalk.*

This plant grows naturally in Egypt, from whence I received the seeds, which were sent by Mr. Forschal,

N U R

one of the persons who were sent by the late king of Denmark, to make discoveries in the East.

It is an annual plant, with trailing stalks which lie prostrate on the ground, and divide into several branches, which are garnished with oval, spear-shaped, smooth leaves, having short foot-stalks; these come out single at some joints; by pairs at others, and frequently three or four at the upper joints: the flowers are produced singly from the forks of the branches; upon pretty long foot-stalks; they are shaped like those of the Winter Cherry; having short tubes, which spread open above, and are of a fine blue colour; these are succeeded by four naked seeds, sitting in the empalement of the flower. This plant flowers in July, and the seeds ripen in the beginning of September. The seeds of this plant must be sown on a hot-bed in March, and when the plants come up and are fit to remove, they should be each transplanted into a small pot filled with light earth, and plunged into a fresh hot-bed to bring the plants forward, otherwise they will not ripen their seeds in this country; but when their flowers open in July, they should have a large share of air admitted to them when the weather is warm, to prevent their flowers falling away without producing seeds: with this management the plants will continue flowering till the early frost destroys them, and their flowers will produce ripe seeds the beginning of September.

NOLI ME TANGERE. See IMPATIENS.

NONSUCH, or FLOWER of BRISTOL. See LYCHNIS.

NORTHERN ASPECT is the least favourable of any in England, as having very little benefit from the sun, even in the height of summer, therefore can be of little use, whatever may have been advanced to the contrary; for although many sorts of fruit-trees will thrive and produce fruit in such positions, yet such fruit can be of little worth, since they are deprived of the kindly warmth of the sun to correct their crude juices, and render them well tasted and wholesome; therefore it is to little purpose to plant fruit-trees against such walls, except it be those which are intended for baking, &c. where the fire will ripen, and render those juices wholesome, which, for want of sun, could not be performed while growing. You may also plant Morello Cherries for preserving, and white and red Currants, to come late, after those which are exposed to the sun are gone; and if the soil be warm and dry, some sorts of summer Pears will do tolerably well on such an exposure, and will continue longer in eating, than if they were more exposed to the sun. But you should by no means plant Winter Pears in such an aspect, as hath been practised by many ignorant persons, since we find, that the best south walls, in some bad years, are barely warm enough to ripen those fruits.

Duke Cherries planted against walls exposed to the North, will ripen much later in the season, and, if the soil is warm, they will be well flavoured, so that hereby this fruit may be continued a month later than is usual.

NUCIFEROUS TREES, are such which produce nuts.

NUMMULARIA. See LYSIMACHIA.

NURSERY, or Nursery-garden, is a piece of land set apart for the raising and propagating all sorts of trees and plants to supply the garden, and other plantations. Of this sort there are a great number in the different parts of this kingdom, but particularly in the neighbourhood of London, which are occupied by the gardeners, whose business it is to raise trees, plants, and flowers for sale; and in many of these there is at present a much greater variety of trees and plants cultivated, than can be found in any other part of Europe. In France, their Nurseries, (which are but few, when compared with those in England) are chiefly confined to the propagation of fruit-trees, from whence they have the appellation of Pepinier. For there is scarce any of those gardens, where a person can be supplied either

either with evergreens, flowering-shrubs, or forest-trees: and in Holland their Nurseries are principally for flowers; some few of them, indeed, propagate tender exotic plants. But those Nurseries in the neighbourhood of London do, several of them, include all these, and from hence most of the curious persons abroad are supplied with furniture for their gardens. But I do not propose in this place, to treat of these extensive Nurseries, or to give a description of them, therefore shall confine myself to treat of such Nurseries only as are absolutely necessary for all lovers of planting, to have upon the spot where they design to make their plantation. For if these are large, the expence of carrying a great number of trees, if the distance is great, will be no small article, beside the hazard of their growing; which, when the plants have been trained up in good land, and removed to an indifferent one, is very great. Therefore it is of the utmost consequence to every planter, to begin by making a Nursery. But in this article I must beg leave to observe, that a Nursery should not be fixed to any particular spot: I mean by this, that it would be wrong to continue the raising of trees any number of years upon the same spot of ground, because hereby the ground will be so much exhausted by the trees, as to render it unfit for the same purpose. Therefore all good Nursery gardeners shift and change their land from time to time, for when they have drawn off the trees from a spot of ground, they either plant kitchen herbs, or other things, upon the ground for a year or two, by which time, as also by dunging and trenching the land, it is recovered, and made fit to receive other trees. But this they are obliged to from necessity, being confined to the same land; which is not the case with those gentlemen, who have large extent of ground in the country. Therefore all such persons I would advise to make Nurseries upon the ground which is intended for planting, where a sufficient number of the trees may be left standing, after the others have been drawn out to plant in other places; which, for all large growing trees, but particularly such as are cultivated for timber, will be found by much the most advantageous method; for all those trees which come up from the seed, or which are transplanted very young into the places where they are designed to remain, will make a much greater progress, and become larger trees, than any of those which are transplanted at a greater age. Therefore the Nurseries should be thinned early, by removing all those trees which are intended for other plantations while they are young, because hereby the expence and trouble of staking, watering, &c. will be saved, and the trees will succeed much better. But in exposed situations, where there are Nurseries made, it will be necessary to permit the trees to stand much longer; that, by growing close together, they may shelter each other, and draw themselves up; and these should be thinned gradually, as the trees advance; for, by taking away too many at first, the cold will check the growth of the remaining trees. But then those trees which are taken out from these Nurseries, after a certain age, should not be depended on for planting; and it will be prudence rather to consign them for fuel, than by attempting to remove them large, whereby, in endeavouring to get them up with good roots, the roots of the standing trees will be often much injured.

What has been here proposed, must be understood for all large plantations in parks, woods, &c. but those Nurseries which are only intended for the raising of evergreens, flowering shrubs, or plants which are designed to embellish gardens, may be confined to one spot, because a small compass of ground will be sufficient for this purpose. Two or three acres of land employed this way, will be sufficient for the most extensive designs, and one acre will be full enough for those of moderate extent. And such a spot of ground may be always employed for sowing the seeds of foreign trees and plants, as also for raising many sorts of biennial and perennial flowers, to transplant into

the borders of the pleasure-garden, and for raising many kinds of bulbous-rooted flowers from seeds, whereby a variety of new sorts may be obtained annually, which will recompense for the trouble and expence, and will moreover be an agreeable diversion to all those persons who delight in the amusements of gardening.

Such a Nursery as this should be conveniently situated for water; for where that is wanting, there must be an expence attending the carriage of water in dry weather. It should also be as near the house as it can with convenience be admitted, in order to render it easy to visit at all times of the year, because it is absolutely necessary that it should be under the inspection of the master, for unless he delights in it, there will be little hopes of success. The soil of this Nursery should also be good, and not too heavy and stiff, for such land will be very improper for sowing most sorts of seeds; because as this will detain the moisture in the spring and winter, the seeds of most tender things, especially of flowers, will rot in the ground, if sown early; therefore where persons are confined to such land, there should be a good quantity of sand, ashes, and other light manures buried, in order to separate the parts, and pulverize the ground; and if it is thrown up in ridges, to receive the frost in winter, it will be of great use to it, as will also the frequent forking, or stirring of the ground, both before and after it is planted.

The many advantages which attend the having such a Nursery, are so obvious to every person who has turned his thoughts in the least to this subject, that it is needless for me to mention them here; and therefore I shall only beg leave to repeat here what I have so frequently recommended, which is, the carefully keeping the ground always clean from weeds; for if these are permitted to grow, they will rob the young trees of their nourishment. Another principal business is, to dig the ground between the young plants at least once every year, to loosen it for the roots to strike out; but if the ground is stiff, it will be better if it is repeated twice a year, viz. in October and March, which will greatly promote the growth of the plants, and prepare their roots for transplanting.

But as there may be some persons who may have the curiosity to raise their own fruit-trees, which is what I would recommend to every one who is a lover of good fruit, because the uncertainty in procuring the intended kinds of each fruit is very great, when taken from common Nursery-gardens, so that most gentlemen who have planted many, have constantly complained of this disappointment; but beside this, there is another inconvenience, which, for want of skill, is scarce taken notice of, which is, the taking the buds or grafts from young trees in the Nurseries which have not borne fruit; this having been frequently repeated, renders the trees so raised as luxuriant as Willows, making shoots to the top of the walls in two or three years, and are rarely after fruitful with the most skilful management: I shall therefore treat of the proper method to make a Nursery of these trees.

In the doing of which you must observe the following rules:

1. That the soil in which you make the Nursery be not better than that where the trees are to be planted out for good; the not observing this is the reason that trees are often at a stand, or make but little progress for three or four years after they come from the Nursery, as it commonly happens to such trees as are raised near London, and carried into the northern parts of England, where, being planted in a poor soil and a much colder situation, the trees seldom succeed well; therefore it is by far the better method (when you have obtained the sorts you would propagate) to raise a Nursery of the several sorts of stocks proper for the various kinds of fruit, upon which you may bud or graft them; and those trees which are thus raised upon the soil, and in the same degree of warmth, where they are to be planted, will succeed much better than those

those brought from a greater distance and from a richer soil.

2. This ground ought to be fresh, and not such as has been already worn out by trees, or other large growing plants, for in such soil your stocks will not make any progress.

3. It ought not to be too wet, nor over dry, but rather of a middling nature; though of the two extremes, dry is to be preferred, because in such soils (though the trees do not make so great a progress as in moist, yet) they are generally sounder, and more disposed to fruitfulness.

4. You must also observe to inclose it, that cattle and vermin may not come in, for these will make sad havoc with young trees, especially in winter, when the ground is covered with snow, that they have little other food which they can come at. Some of the most mischievous of these animals are hares and rabbits, which are great destroyers of young trees at that season, by eating off all their bark; therefore you must carefully guard your Nursery against these enemies.

The ground being inclosed, should be carefully trenched about eighteen inches, or two feet deep, provided it will allow it; this should be done in August or September, that it may be ready to receive young stocks at the season for planting, which is commonly in the middle end of October. In trenching the ground, you must be very careful to cleanse it from the roots of all noxious weeds, such as Couch-grass, Docks, &c. which, if left in the ground, will get in among the roots of the trees, so as not to be gotten out afterwards, and will spread and over-run the ground, to the great prejudice of your young stocks.

After having dug the ground, and the season being come for planting, you must level down the trenches as equal as possible, and then lay out the ground into quarters, proportionable to the size thereof, and those quarters may be laid out in beds, for the sowing of seeds or the stones of fruit.

The best sort of stocks for Peaches, Nectarines, &c. are such as are raised from the stones of the Muscicle and white Pear Plumb, but you should never plant suckers of these (which is what some people practise) for these seldom make so good stocks, nor are ever well-rooted plants; besides, they are very subject to produce great quantities of suckers from their roots, which are very troublesome in the borders, or walks of a garden, and greatly injure the tree; so that you should annually, or at least every other year, sow a few stones of each, that you may never be at a loss for stocks.

For Pears, you should have such stocks as have been raised from the kernels of the fruit where perry hath been made, or else preserve the seeds of some sorts of summer Pears, which generally shoot strong and vigorous, as the Cuisse Madame, Windsor, &c. but when this is intended, the fruit should be suffered to hang upon the trees till they drop, and afterward permitted to rot; then take out the kernels and put them in sand, being careful to keep them from vermin, as also to place them where they may not be too damp, which will cause them to grow mouldy. These you should sow for stocks early in the spring, upon a bed of good light fresh earth, where they will come up in about six weeks, and, if kept clear from weeds, will be strong enough to transplant the October following. But for many sorts of summer and autumn Pears, Quince stocks are preferable to free (i. e. Pear) stocks; these are generally used for all the sorts of soft-melting Pears, but they are not so good for the breaking Pears, being apt to render those fruits which are grafted upon them stony; these are very often propagated from suckers, which are generally produced in plenty from the roots of old trees; but those are not near so good as such as are propagated from cuttings or layers, which have always much better roots, and are not so subject to produce suckers as the other, which is a very desirable quality, since these suckers do not only rob the trees of part of

their nourishment, but are very troublesome in a garden.

Apples are grafted or budded upon stocks raised from seeds which come from the cyder-press, or upon Crab stocks, the latter of which are esteemed for their durableness, especially for large standard trees; these should be raised from seeds, as the Pear stock, and must be treated in the same manner, for those procured from suckers, &c. are not near so good; but for small gardens, the Paradise stock hath been for some years past greatly esteemed, it being of very humble growth, causeth the fruit-trees grafted or budded thereon to bear very soon, and they may be kept in small compass; but these are only proper for very small gardens, or by way of curiosity, since the trees thus raised are but of short duration; and seldom arise to any size to produce fruit in quantities, unless the graft or bud be buried in planting, so that they put forth roots, and then they will be equal to trees grafted upon free stocks, since they receive but small advantage from the stock.

For Cherries, you should make use of stocks raised from the stones of the common Black, or the wild Honey Cherry, both of which are strong free growers, and produce the cleanest stocks.

For Plumbs, you may use the stones of most free-growing sorts, which will also do very well for Apricots, these being not so difficult to take as Peaches or Nectarines; but (as I said before) these should not be raised from suckers for the reason there assigned, but rather from stones.

There are some persons who recommend the Almond stock for several sorts of tender Peaches, upon which they will take much better than upon Plumb stocks; but these being tender in their roots, and apt to shoot early in the spring, and being of short duration, are by many people rejected; but such tender sorts of Peaches which will not take upon Plumb stocks, should be budded upon Apricots, upon which they will take very well; and all sorts of Peaches which are planted upon dry soils, will continue much longer, and not be so subject to blight, if they are upon Apricots; for it is observed, that upon such soils where Peaches seldom do well, Apricots will thrive exceedingly, which may be owing to the strength and compactness of the vessels in the Apricots, which render it more capable of assimilating, or drawing its nourishment from the Plumb stock, which in dry soils seldom afford it in great plenty to the bud; and the Peach-tree being of a loose spongy nature, is not so capable to draw its nourishment therefrom, which occasions that weakness which is commonly observed in those trees, when planted on a dry soil; therefore it is the common practice of the Nursery-gardeners, to bud the Plumb stocks either with Apricots, or some free growing Peach; and after these have grown a year, they bud the tender sorts of Peaches upon these shoots, by which method many sorts succeed well, which in the common way will not thrive, or scarce keep alive; and these the gardeners term double worked Peaches.

There are some people who of late have budded and grafted Cherries upon stocks of the Cornish, and others on the Morello Cherry, which, they say, will render the trees more fruitful, and less luxuriant in growth, so that they may be kept in less compass; these stocks having the same effect upon Cherries, as the Paradise stock hath on Apples.

Having provided yourself with young stocks of all these different sorts, which should be raised in the seminary the preceding year, you should proceed to transplanting them in October (as was before directed) into the Nursery. The distance which they should be planted, if designed for standards, should be three feet and a half or four feet, row from row, and a foot and a half distant in the rows; but if for dwarfs, three feet row from row, and one foot in the rows, will be a sufficient distance.

In taking these stocks out of the seed-beds, you must raise the ground with a spade, in order to preserve

the roots as entire as possible; then with your knife you should prune off all the very small fibres; and if there are any which have a tendency to root downright, such roots should be shortened; then having thus prepared the plants, you should draw a line across the ground intended to be planted, and with your spade open a trench thereby exactly strait, into which you should place them at the distance before-mentioned, setting them exactly upright; and then put the earth in close to them, filling up the trench, and with your foot press the earth gently to the roots of them, observing not to displace them so as to make the rows crooked, which will render them unsightly; these plants should by no means be headed, or pruned at top, which will weaken them, and cause them to produce lateral branches, and thereby spoil them.

If the winter should prove very cold, it will be of great service to your young stocks, to lay some mulch upon the surface of the ground near their roots, which will prevent the frost from penetrating the ground, so as to hurt the tender fibres which were produced after planting; but you should be careful not to let it lie too thick near the stems of the plants, nor remain too long, lest the moisture should be prevented from penetrating to the roots of the plants, which it often does, where there is not due care taken to remove it away as soon as the frost is over.

In the summer season you must always observe to hoe and destroy the weeds, which, if permitted to remain in the Nursery, will greatly weaken and retard the growth of your stocks; and, the succeeding years, you should observe to dig up the ground every spring between the rows, which will loosen it so, as that the fibres may easily strike out on each side, and the weeds will thereby be destroyed; you should also observe, where any of the stocks have shot out lateral branches, to prune them off, that they may be encouraged to grow upright and smooth.

The second year after planting, such of the stocks as are designed for dwarf trees will be fit to bud, but those which are designed for standards, should be suffered to grow six or seven feet high before they are budded or grafted. The manner of budding and grafting being fully described under their respective heads, I shall not repeat them in this place, nor need I say any thing more of treating these trees after budding, that being also treated of under the several articles of fruits; I shall only add, that those stocks which were budded in the summer, and have failed, may be grafted the following spring, but Peaches and Nectarines never take well from grafts, these should therefore be always budded.

The ground you intend for the Flower-nursery should be well situated to the sun, but defended from strong winds, by plantations of trees or buildings, and the soil should be light and dry; which must always be observed, especially for bulbous-rooted flowers, which are designed to be planted therein, the particulars of which are exhibited under the several articles of flowers.

In this Nursery should be planted the offsets of all your bulbous-rooted flowers, where they are to remain until they become blowing roots, when they should be removed into the pleasure-garden, and planted either in beds or borders, according to the goodness of the flowers, or the management which they require.

You may also in this ground raise the several sorts of bulbous-rooted flowers from seed, by which means new varieties may be obtained; but most people are discouraged from setting about this work, from the length of time before the seedlings will come to flower: however, after a person hath once begun, and constantly continued sowing every year, after the parcel first sown has flowered, the regular succession of them coming annually to flower, will not render this method so tedious as it at first appeared.

The seedling Auriculas, Polyanthus, Ranunculuses, Anemonies, Carnations, &c. should be raised in this

Nursery, where they should be preserved until they have flowered, when you should mark all such as are worthy of being transplanted into the flower-garden, which should be done in their proper seasons; for it is not so well to have all these seedling flowers exposed to public view in the flower-garden, because it always happens, that there are great numbers of ordinary flowers produced amongst them, which will make but an indifferent appearance in the pleasure-garden.

NYCTANTHES. Lin. Gen. Plant. 16. Jasminum. Raii Meth. Plant. *Arabian Jasmine*.

The CHARACTERS are,

The empalement of the flower is cylindrical, permanent, and of one leaf, cut into eight or ten acute segments. The flower is of the salver-shape, of one leaf, with a cylindrical tube longer than the empalement, cut into eight or ten segments at the top, which spread open. It hath two small awl-shaped stamina, situated at the bottom of the tube, terminated by erect summits, and one roundish depressed germen, supporting a single style the length of the tube, crowned by a bifid erect stigma. The germen afterward becomes a roundish berry with two cells, each containing a large roundish seed. This genus of plants is ranged in the first section of Linnaeus's second class, which includes those plants whose flowers have two stamina and one style.

The SPECIES are,

1. **NYCTANTHES** (*Sambac*) caule volubili, foliis subovatis acutis. Hort. Upsal. 4. *Nyctanthes with a winding stalk and acute leaves.* Jasminum Arabicum. Clus. Cur. 3. *The Arabian Jasmine.*
2. **NYCTANTHES** (*Hirsuta*) petiolis pedunculisque villis. Lin. Sp. Plant. 6. *Nyctanthes with the foot-stalks of the leaves and flowers hairy.* Jasminum Indicum bacciferum, flore albo majore, noctu olente. Com. Hort. Mal. *Indian berry-bearing Jasmine, with a larger white flower, smelling by night.*

The first sort grows naturally in India, from whence it has been formerly brought to the islands in America, where the plants are cultivated for ornament; this rises with a winding stalk to the height of fifteen or twenty feet, sending out many small branches, garnished with oval smooth leaves near three inches long, and almost two broad, of a light green, standing opposite on short foot-stalks, ending in acute points. The flowers are produced at the end of the branches, and also upon the side shoots, upon short foot-stalks; each generally sustain three flowers, the two lower being opposite, and the middle ones longer: these have cylindrical empalements, which are short, and are cut almost to the bottom into eight narrow segments. The tube of the flower is narrow, about half an inch long, and is cut at the top into eight obtuse segments, which expand quite flat; they are of a pure white, and have a most agreeable odour, somewhat like the Orange-flower, but sweeter; these flowers, when fully blown, drop out of their cups upon being shaken, and frequently fall in the night, so that when the plants are in full flower, the place under them is often covered with flowers in the morning, which soon change to a purplish colour. The plants continue flowering great part of the year, when they are kept in a proper temperature of warmth.

There is a variety of this sort with very large double flowers, having a most agreeable odour, which grows naturally at Malabar, where the women string the flowers to hang round their necks, and by way of ornament. This sort was, some years past, growing in the gardens at Hampton-Court, but was afterward lost, with many other rare plants, by the ignorance of the gardener; and, for several years past, was only known to grow in the gardens of the Duke of Tuscany in Europe, who kept a constant guard over the plants, so that neither cuttings or layers might be taken from them, so as to be propagated; but I have lately received a plant of this sort, which was brought from the Malabar coast, with several other

rare

rare plants, by Captain Quick; and this is at present in so flourishing a state of health, that I hope soon to increase the number of plants, which will be a great acquisition to the English gardens.

Linnæus has supposed that sort of Jasmine, to which the title of Gardenia has been given, to be the same with this; but as my plant has flowered here, so it appears plainly to be an accidental variety of this Nyctanthes, the flowers changing to a purple colour before they drop off, whereas the plant titled Gardenia changes to a buff colour; beside, this Nyctanthes is a twining plant, whereas the other is of upright growth: he is likewise as much mistaken in supposing it to be the same with Rumphius's plant, for it differs in many respects from that, as also from Burman's figure; therefore if he had looked upon the figure, and attended to the description given of this plant in the Pisa Garden, he could not have supposed these two to be the same plant.

The second sort grows naturally in India, where it rises to the height of a tree, dividing into many branches, garnished with large, oval, smooth leaves, of a lucid green, with hairy foot-stalks; these come out on every side the branches without order. The flowers are produced on the side of the branches from the wings of the leaves, upon long hairy foot-stalks, each sustaining seven or eight flowers, which are of a pure white, and very fragrant, but have longer tubes than those of the former sort. The flowers of this plant open in the evening, and drop off in the morning, which has occasioned some to give it the title of Arbor Tristis, or the Sorrowful-tree, from its casting the flowers in the morning; this is very rare in Europe at present.

The plants of the first sort are frequently brought from Italy by the Italian gardeners, who bring Orange-trees here for sale; but those plants are always grafted upon stocks of the common Jasmine, which do not keep pace in their growth with the graft, so become very unsightly, when the plants are grown to any size; besides, the stocks are very subject to shoot from the bottom; and if these shoots are not constantly rubbed off, they will draw the nourishment from the graft and starve it: therefore the best method to obtain the plants, is to propagate them by layers or cuttings; the former is the surest method, for unless the cuttings are very carefully managed, they will not take root; and as the stalks of this sort are pliable, they may be easily brought down, and laid in pots filled with a soft loamy soil, which should be plunged into a hot-bed of tan: if the branches are laid down in the spring and carefully watered, they will put out roots by autumn, when they may be cut from the old plants, and each transplanted into a separate small pot, and then plunged into the tan-bed, where they should be shaded from the sun till they have taken new root.

If these plants are propagated by cuttings, they should be planted from May to August, into pots filled with the before-mentioned earth, and plunged into a moderate hot-bed of tanners bark. The pots should be pretty large, and there may be ten or twelve cuttings planted in each; if these pots are closely covered with bell or hand-glasses to exclude the air, it will greatly promote their taking root; they must also be shaded from the sun in the heat of the day, and gently refreshed with water when the earth is dry; with this management the cuttings will have taken root by August, when they may be transplanted into separate pots, and treated in the same way as the layers.

These plants may be preserved in a moderate degree of warmth, but if they are plunged into the tan-bed of the bark-stove, they will thrive much better, and produce a greater quantity of flowers; and as the leaves continue all the year, the plants will make a fine appearance in the stove at all seasons, and produce flowers great part of the year.

The second sort requires the same treatment, but is

much more difficult to propagate, so is very rarely found in the European gardens; there were two or three of these plants brought from Florence a few years since, but they were put into the hands of unskilful persons, so were lost.

N Y M P H Æ A. Tourn. Inst. R. H. 260. tab. 137, 138. Lin. Gen. Plant. 579. [is so called, because it grows in water, which the poets feign to be the residence of the nymphs.] The Water Lily; in French; *Nemfar*.

The CHARACTERS are,

The empalement of the flower is composed of four or five coloured leaves, and is permanent. The flower hath many petals which are smaller than the empalement, sitting on the side of the germen, for the most part in a single series. It hath a great number of short, plain, incurved stamina, with oblong summits, like threads, growing to their borders. It hath a large oval germen, but no style, with an orbicular, plain, target-shaped stigma, sitting close, whose border is crenated and is permanent. The germen afterward becomes a hard, oval, fleshy fruit, with a rude narrow neck, crowned at the top, and divided into ten or fifteen cells full of pulp, with many roundish seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, which contains those plants whose flowers have many male parts and but one female.

The SPECIES are,

1. **N Y M P H Æ A** (*Lutea*) foliis cordatis integerrimis, calyce petalis majore pentaphyllo. Flor. Lap. 218. *Water Lily with entire heart-shaped leaves, whose empalement consists of five leaves larger than the petals. Nymphaea lutea major. C. B. P. 193. Greater yellow Water Lily.*
2. **N Y M P H Æ A** (*Alba*) foliis cordatis integerrimis, calyce quadrifido. Lin. Sp. Plant. 510. *Water Lily with heart-shaped entire leaves, and a four-pointed empalement. Nymphaea alba major. C. B. P. 193. Greater white Water Lily.*

There are some other species of this genus which are natives of warm countries, but as they cannot without great difficulty be cultivated here, so I shall not enumerate them; for unless there is a contrivance for standing water in the stove, in which the plants may be planted, they will not grow; and such a place would be injurious to most other plants in the stove, by occasioning damps; so that unless a stove was contrived on purpose for some of these aquatic plants, it would be imprudent to attempt their cultivation.

The two sorts here mentioned, grow naturally in standing waters in many parts of England; they have large roots, which are fastened in the ground, from which arise the stalks to the surface of the water, where the leaves expand and float; they are large, roundish, and heart-shaped. The flowers arise between the leaves, and swim upon the surface of the water. The white sort has a faint sweet scent; these appear in July, and are succeeded by large roundish seed-vessels, filled with shining black seeds, which ripen toward the end of August, when they sink to the bottom of the water.

The best method to propagate these plants is, to procure some of their seed-vessels just as they are ripe and ready to open; these should be thrown into canals, or large ditches of standing water, where the seeds will sink to the bottom, and the following spring the plants will appear floating upon the surface of the water, and in June and July will produce their beautiful large flowers. When they are once fixed to the place, they will multiply exceedingly, so as to cover the whole surface of the water in a few years.

In some small gardens I have seen the plants cultivated in large troughs of water, where they have flourished very well, and have annually produced great quantities of flowers; but as the expence of these troughs is pretty great (their insides requiring to be lined with lead, to preserve them) there are but few people who care to be at that charge.

 BECKIA.
O CHRUS. See PISUM.
O CULUS CHRISTI. See HORMINUM SYL-
 VESTRE.
O CYMUM. Tourn. Inst. R. H. 203. tab. 96. Lin.
 Gen. Plant. 651. Basil; in French, *Basilic*.

The CHARACTERS are,

The empalement of the flower is short, permanent, of one leaf, divided into two lips; the upper lip is plain, bifid, and heart-shaped; the under is cut into four acute segments. The flower is of the lip kind, of one petal inverted. It has a short spreading tube; the rising lip is broad, and cut into four obtuse equal parts; the reflexed lip is long, narrow, and sawed. It hath four stamina in the lower lip, which are deflexed, two of which are a little longer than the other, terminated by half-moon-shaped summits. The germen is divided into four parts, supporting a slender style, situated with the stamina, crowned by a bifid stigma. The germen afterward become four naked seeds inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, which contains those plants whose flowers have two long and two shorter stamina, and their seeds have no covering.

The SPECIES are,

1. **O** CYMUM (*Basilicum*) foliis ovatis glabris, calycibus ciliatis. Hort. Cliff. 315. Basil with oval smooth leaves, and hairy empalements. *Ocymum caryophyllatum majus*. C. B. P. 226. Greater Clove-scented, or common Basil.
2. **O** CYMUM (*Minimum*) foliis ovatis integerrimis. Hort. Upsal. 169. Basil with oval entire leaves. *Ocymum minimum*. C. B. P. 226. The least Basil, commonly called Bush Basil.
3. **O** CYMUM (*Medium*) hirsutum, foliis ovato-lanceolatis acuminatis dentatis. Hairy Basil with oval spear-shaped leaves which are indented, and end in acute points. *Ocymum medium vulgatum & nigrum*. J. B. 3. p. 2. 247. Common middle black Basil.
4. **O** CYMUM (*Americanum*) foliis ovato-oblongis serratis, bracteis cordatis reflexis concavis spicis filiformibus. Lin. Sp. Plant. 833. Basil with oval, oblong, sawed leaves, and heart-shaped, concave, reflexed bractea.
5. **O** CYMUM (*Campechianum*) foliis lanceolatis subtus incanis, petiolis longissimis villosis floribus pedunculatis. Basil with spear-shaped leaves, which are hoary on their under side, and very long hairy foot-stalks to the flowers. *Ocymum Campechianum odoratissimum*. Houst. MSS. The sweetest-scented Basil of Campeachy.
6. **O** CYMUM (*Frutescens*) racemis secundis lateralibus, caule erecto. Lin. Sp. Plant. 832. Basil with fruitful spikes of flowers on the side of the stalk, which are erect. *Ocymum Zeylanicum*, perenne, odoratissimum latifolium. Burm. Zeyl. 174. tab. 80. fol. 1. Sweet-scented perennial Basil of Ceylon, with broad leaves.

The three first sorts grow naturally in India and Persia; of these there are a great variety, which differ in the size, shape, and colour of their leaves, as also in their odour; but as these differences are accidental, so I have not enumerated them, being convinced from repeated experiments, that the seeds of one plant will produce many varieties.

The first sort rises with a branching stalk a foot and a half high; the leaves are large, oval, and smooth;

O C Y

the stalk is hairy, and four-cornered; the leaves are placed by pairs opposite, and the branches also come out in the same manner; the stalk is terminated by a whorled spike of flowers, which is five or six inches long, and the branches are also terminated by short spikes of flowers of the same sort; the whole plant has a strong scent of Cloves.

Of this there are the following varieties:

1. The fringed-leaved Basil with purple leaves.
2. The green fringed-leaved Basil.
3. The green Basil with studded leaves.
4. The large-leaved Basil.

The second sort is a low bushy plant, which seldom rises more than six inches high, spreading out into branches from the bottom, forming an orbicular head; the leaves are small, oval, and smooth, standing opposite on short foot-stalks. The flowers are produced in whorls toward the top of the branches; they are smaller than those of the former sort, and are seldom succeeded by ripe seeds in England.

Of this there are some varieties, as

1. The smallest Basil with black purple leaves.
2. The smallest Basil with variable leaves.

The third sort is the common Basil which is used in medicine, and also in the kitchen, particularly by the French cooks, who make great use of it in their soups and sauces. This rises about ten inches high, sending out branches by pairs opposite, from the bottom; the stalks and branches are four-cornered; the leaves are oval, spear-shaped, ending in acute points, and are indented on their edges; the whole plant is hairy, and has a strong scent of Cloves, too powerful for most persons, but to some it is very agreeable: the whole plant is an ingredient in the compound Briony-water.

There are some varieties of this species, viz.

1. Common Basil with very dark green leaves, and a Violet-coloured flower.
2. Curled-leaved Basil with short spikes of flowers.
3. Narrow-leaved Basil smelling like Fennel.
4. Middle Basil with a scent of Citron.
5. Basil with studded leaves.
6. Basil with leaves of three colours.

The fourth sort grows naturally in India; this rises with a branching stalk a foot and a half high, which is taper, and of a purplish colour; the leaves are short and hairy; they are of an oval oblong figure, ending in obtuse points, and are sawed on their edges, standing upon pretty long foot-stalks. The stalks are terminated by three spikes of flowers, that in the middle being longer than the other two; the spikes are narrow, and the flower have short foot-stalks; under each whorl of flowers are two small leaves (or bractea) placed opposite, which are heart-shaped, concave, and reflexed. The flowers are small, and in some plants are of a purplish colour, but in general they are white; their empalements are smooth, and cut into five parts at the top; the style of the flower is longer than the petal, and the whole plant has a strong, sweet, aromatic odour.

The fifth sort rises with an upright stalk near two feet high, sending out sometimes two, and at others four branches towards the top, opposite, garnished with spear-shaped leaves about three inches long, and one broad in the middle, lessening at both ends to a point; their foot-stalks are two inches long, and are hairy.

The

The flowers grow in whorled spikes at the top of the stalks, the flowers standing upon foot-stalks, each sustaining three flowers; these are about the size of those of the common Basil, and are white; the whole plant has a strong aromatic odour. It grows naturally at Campeachy.

The sixth sort grows naturally in the island of Ceylon; this rises with a square stalk two feet high, which is hairy, and divides into three branches at the top; the lower leaves are roundish, ending in points; they are hairy, and crenated on their edges, standing upon slender foot-stalks; the leaves on the stalks are narrower and shorter, and have foot-stalks an inch long; the stalks are terminated by three spikes of flowers in whorls, that in the middle being the longest. The flowers are reflexed and hang downward, they are white, and larger than those of the common sort. This plant has less odour than the other sorts.

These plants being most of them annual, are propagated from seeds, which should be sown in March, upon a moderate hot-bed; and when the plants are come up, they should be transplanted into another moderate hot-bed, observing to water and shade them until they have taken root; after which they should have plenty of air in mild weather, otherwise they will draw up very weak; you must also water them frequently, for they love moisture. In May they should be taken up with a ball of earth to their roots, and transplanted either into pots or borders, observing to shade them until they have taken root; after which they will require no farther care but to clear them from weeds, and refresh them with water in dry weather. Though these plants are only propagated from seeds, yet if you have any particular sort which may arise from seeds, which you are desirous to increase, you may take off cuttings any time in May, and plant them on a moderate hot-bed, observing to water and shade them for about ten days; in which time they will take root, and in three weeks time be fit to remove, either into pots or borders, with the seedling plants. In September these plants will perfect their seeds, when those sorts which appear the most distinct, should have their seeds preserved separate, for sowing the following spring.

The seeds of these plants are usually brought from the south of France or Italy every spring, because some of them seldom ripen their seeds in this country in the open air. But whoever is curious to preserve the seeds of any of the varieties, should place them in an airy glass-case or stove in the autumn, when the weather begins to be cold or wet; and by supplying them with water, and letting them have free air every day in mild weather, they will perfect their seeds very well in this country.

The fifth sort is more tender than any of the other; this was discovered growing wild at Campeachy, by the late Dr. William Houstoun, who sent the seeds to England. This should be sown on a hot-bed early in the spring, and when the plants are come up, they should be transplanted on another very temperate hot-bed to bring them forward; and when they have obtained strength, they should be each transplanted into a separate pot, and placed either in the stove, or on a moderate hot-bed, where they may have a large share of air in warm weather; but by being sheltered from the cold and wet, the plants will perfect their seeds very well in England.

The sixth sort grows to be shrubby, and if placed in a moderate warmth in winter, may be preserved two years; but this will ripen its seeds the first year, if the plants are brought forward in the spring; but if this should fail, the plants may be placed in the stove, where they may be kept through the winter, and the following season they will perfect their seeds. In the summer the plants should be placed in the open air in a sheltered situation, and in warm weather they should have plenty of water.

There have been many fictitious stories handed down through several generations, of scorpions being bred

in the brain of persons who frequently smelled this plant; and others have asserted, that scorpions commonly breed under the plants, but these stories are without foundation: but it is certain, that the odour of these plants is too strong for most persons, especially in a room, or if near them; for which reason they should not be placed too near the habitation, because if they are in any quantity, the odour will extend at times to most of the apartments when the windows are open.

CENANTHE. Tourn. Inst. R. H. 312. tab. 166. Lin. Gen. Plant. 314. [*Olivabn*, of *Olyn*, a Vine, and *Abos*, a flower. The ancients called any plant *Cenante* that flowered at the same time with the Vine, or whose flowers had the same odour.] Water Dropwort.

The CHARACTERS are,

It is a plant with an umbelliferous flower; the principal umbel has but few rays, but the particular umbels have many short ones. The principal involucre is composed of many single leaves, which are shorter than the umbel; the smaller umbels have many small leaves; the rays of the principal umbel are difform. Those flowers in the disk are hermaphrodite, and are composed of five heart-shaped inflexed petals, which are almost equal; those of the rays are male, and have five large unequal petals which are bifid; they have five single stamina terminated by roundish summits. The germen is situated under the flower, supporting two acrol-shaped permanent styles, crowned by obtuse stigmas. The germen afterward becomes an oval fruit, divided into two parts, containing two almost oval seeds, convex on one side and plain on the other.

This genus of plants is ranged in the second section of Linnæus's fifth class, which contains those plants whose flowers have five stamina and two styles.

The SPECIES are,

1. **CENANTHE** (*Crocata*) foliis omnibus multifidis obtusis subæqualibus. Hort. Cliff. 99. *Water Dropwort*, whose leaves all end in many obtuse points, and are almost equal. *Cenante* succo viroso, cicuta facie lobelii. J. B. 3. p. 2. 193. *Hemlock Dropwort*.
2. **CENANTHE** (*Fistulosa*) stolonifera, foliis caulinis pinatis filiformibus fistulosis. Lin. Sp. Plant. 254. *Water Dropwort*, with slender, fistular, winged leaves growing on the stalks. *Cenante aquatica*. C. B. P. 162. *Water Dropwort*.
3. **CENANTHE** (*Pimpinelloides*) foliolis radicalibus cuneatis fissis, caulinis integris linearibus longissimis canaliculatis. Hort. Cliff. 99. *Water Dropwort* whose lower leaves are oval and cut, but those on the stalks entire, narrow, and channelled. *Cenante apii folio*. C. B. P. 162. *Water Dropwort* with a Smallage leaf.
4. **CENANTHE** (*Prolifera*) umbellularum pedunculis marginalibus longioribus ramosis masculis. Hort. Upal. 63. *Water Dropwort* whose foot-stalks on the borders of the umbels are longer, branching, and bear male flowers. *Cenante prolifera* Apula. C. B. P. 163. *Childing Water Dropwort* of Apulia.
5. **CENANTHE** (*Globulosa*) fructibus globosis. Hort. Cliff. 99. *Water Dropwort* with globular fruit. *Cenante Lusitanica*, semine crassiore globoso. Tourn. Inst. 313. *Portugal Water Dropwort*, with a thicker globular seed.

The first of those here mentioned, is very common by the sides of the Thames on each side London, as also by the sides of large ditches and rivers in divers parts of England: this plant commonly grows four or five feet high with strong jointed stalks, which, being broken, emit a yellowish foetid juice; the leaves are somewhat like those of the common Hemlock, but are of a lighter green colour: the roots divide into four or five large taper ones, which, when separated, have some resemblance to Parsneps; for which some ignorant persons have boiled them, whereby themselves and family have been poisoned.

This plant is one of the most poisonous we know; the juice which is at first like milk, turns afterward to a Saffron colour: if a person should swallow ever so little of this juice, it will so contract every part it

touches, that there will immediately follow a terrible inflammation and gangrene: and what is worse, there has not yet been found an antidote against it; for which reason, we ought to be very careful to know this plant, in order to avoid it, for fear we should take it for any other like it, which would certainly prove fatal.

The poisonous quality of this plant, had led some persons to believe it to be the *Cicuta* of the ancients; but according to Wepfer, the *Sium alterum olusatricum* of Lobel, is what the ancients called *Cicuta*, as may be seen at large in Wepfer's book *De Cicuta*.

The second sort is very common in moist soils, and by the sides of rivers in divers parts of England: this is not supposed to be near so strong as the first, but is of a poisonous quality.

All the sorts of these plants naturally grow in moist places, so that whoever hath a mind to cultivate them, should sow their seeds soon after they are ripe in autumn, upon a moist soil, where they will come up, and thrive exceedingly the following summer, and require no farther care but to clear them from weeds.

ÆNOTHERA. Lin. Gen. Plant. 424. *Onagra*. Tourn. Inst. R. H. 302. tab. 156. Tree Primrose.

The CHARACTERS are,

The empalement of the flower is of one leaf, having a long cylindrical tube, cut into four acute segments at the brim, which turn backward. The flower has four heart-shaped petals, which are lengthways inserted in the divisions of the empalement. It hath eight awl-shaped incurved stamina, which are inserted in the tube of the empalement, and are terminated by oblong prostrate summits. The cylindrical germen is situated under the tube of the empalement, supporting a slender style, crowned by a thick quadrifid, obtuse, reflexed stigma. The germen afterward becomes a four-cornered cylindrical capsule having four cells, which are filled with small angular seeds.

This genus of plants is ranged in the first section of Linnaeus's eighth class, which includes those plants whose flowers have eight stamina and one style.

The SPECIES are,

1. **ÆNOTHERA** (*Biennis*) foliis ovato-lanceolatis planis, caule muricato subvillosa Vir. Cliff. 33. Tree Primrose, with plain, oval, spear-shaped leaves, and a rough hairy stalk. *Onagra latifolia*. Tourn. Inst. 302. Broad-leaved Tree Primrose.
2. **ÆNOTHERA** (*Angustifolia*) foliis lanceolatis dentatis, caule hispido. Tree Primrose with spear-shaped indented leaves, and a prickly stalk. *Onagra angustifolia*, caule rubro, flore minore. Tourn. Inst. R. H. 302. Narrow-leaved Tree Primrose, with a red stalk and a smaller flower.
3. **ÆNOTHERA** (*Glabra*) foliis lanceolatis planis, caule glabro. Tree Primrose with plain spear-shaped leaves, and a smooth stalk.
4. **ÆNOTHERA** (*Mollissima*) foliis lanceolatis undulatis. Vir. Cliff. 33. Tree Primrose with waved spear-shaped leaves. *Onagra Bonariensis villosa, flore mutabili*. Hort. Elth. 297. Hairy Tree Primrose of Buenos Ayres, with a changeable flower.
5. **ÆNOTHERA** (*Pumila*) foliis radicalibus ovatis, caulibus lanceolatis obtusis, capsulis ovatis sulcatis. Tab. 188. Tree Primrose with oval leaves at the root, those on the stalks spear-shaped, blunt-pointed, and oval furrowed seed-vessels.

The other species which have been formerly placed in this genus, are now under *JUSSIEA* and *LUDWIGIA*, to which the reader is desired to turn.

The three first sorts grow naturally in Virginia, and in other parts of North America, from whence their seeds were brought to Europe in the beginning of the sixteenth century; but they are now become so common in many parts of Europe, as to be taken for natives. The first hath a long, thick, taper root, which runs deep into the ground, from which arise many obtuse leaves which spread flat on the ground; between these the stalks come out, which rise between three and four feet high, and is of a pale green colour, a little hairy, and about the thickness of a

finger, full of pith; this is garnished with long narrow leaves set close to the stalk, without order. The flowers are produced all along the stalk from the wings of the leaves, the germen sitting close to the stalk, from the top of which arises the tube of the flower, which is narrow, more than two inches long; at the top is the empalement, which is cut into four acute segments, which are reflexed downward. The petal of the flower is cut into four large obtuse segments, which in the evening are expanded quite flat, but are shut in the day; these are of a bright yellow colour. From the flower opening in the evening, many persons call it the Night Primrose. The plants begin to flower about Midsummer, and as the stalks advance in height, so other flowers are produced, whereby there is a succession of flowers on the same plant till autumn.

The second sort hath red stalks, which are set with rough protuberances: it does not rise so high as the first, the leaves are narrower, and the flowers are smaller.

The third sort differs from the first, in having shorter stalks, narrower leaves, and smaller flowers; and from the second, in having smooth stalks, which are of a pale green colour. These differences are permanent, so they are undoubtedly different species.

The fourth sort grows naturally at Buenos Ayres; this hath a shrubby stalk more than two feet high, hairy, garnished with narrow spear-shaped leaves ending in acute points; these sit close to the stalks, being a little waved on their edges. The flowers come out from the wings of the leaves along the stalks, like the other sorts; they are first of a pale yellow, but as they decay change to an Orange colour; they are smaller than those of either of the former sorts, and expand only in the evening; the seed-vessels are slender, taper, and hairy. This flowers at the same time with the former.

The fifth sort grows naturally in Canada, from whence the seeds were brought to Paris a few years past. This is a perennial plant; the root is fibrous; the lower leaves are oval and small, sitting close to the ground; the stalk is slender, near a foot high, and is garnished with small spear-shaped leaves, of a light green, ending in blunt points, sitting close to the stalks. The flowers come out from the wings of the leaves like the other species; these are small, of a bright yellow colour, and appear at the same time as the former, and are succeeded by short, oval, furrowed seed-vessels, filled with small seeds.

The three first sorts are very hardy plants, and if once brought into a garden, and the seeds permitted to scatter, there will be a supply of plants without any care. They are biennial, and perish after they have perfected their seeds. The seeds of these plants should be sown in the autumn, for those which are sown in the spring seldom rise the same year: when the plants come up, they should be thinned and kept clean from weeds, which is all the care they require till the autumn, when they should be transplanted to the places where they are designed to flower; but as the roots of these plants strike deep in the ground, so there should be care taken not to cut or break them in removing. The plants will thrive in almost any soil or situation, and will flower in London in small gardens, better than most other plants.

The fourth sort is now become pretty common in the English gardens, for if the seeds of this are permitted to scatter, the plants will come up the following spring, and require no other care but to keep them clean from weeds, and thin them where they grow too close. If these plants are kept in pots, and placed in a green-house in the autumn, they will live through the winter; but as they produce flowers and seeds in the open air, the plants are seldom preserved longer.

The fifth sort is perennial, and may be propagated either by parting of the roots, or by seeds: if it is by the former, the best time for doing it is in the spring; but

OLE

but if they are propagated by seeds, these should be sown in the autumn; and the surest way is to sow the seeds in pots, and place them under a hot-bed frame in winter: in the spring the plants will appear, and when they are fit to remove, a few of them may be planted in small pots, to be sheltered under a common frame in the winter; and the others may be planted in a sheltered border, where they will endure the cold of our ordinary winters very well, and the following summer they will produce flowers and seeds in plenty; so there will be little occasion for parting of their roots, because the seedling plants will be much stronger and flower better, than those propagated by offsets.

OLDENLANDIA. Plum. Nov. Gen. 42. tab. 36. Lin. Gen. Plant. 143.

The CHARACTERS are,

The empalement of the flower is permanent, sitting upon the germen, and is cut into five parts. The flower has four oval petals which spread open, and are double the length of the empalement, and four stamina terminated by small summits. It hath a roundish germen situated under the flower, supporting a single style, crowned by an indented stigma. The germen afterward turns to a globular capsule with two cells, filled with small seeds.

This genus of plants is ranged in the first section of Linnaeus's fourth class, which includes those plants whose flowers have four stamina and one style.

We have but one SPECIES of this genus in the English gardens, which is,

OLDENLANDIA (*Corymbosa*) pedunculis multifloris, foliis lineari-lanceolatis. Lin. Sp. Plant. 119. *Oldenlandia* with many flowers on a foot-stalk, and linear spear-shaped leaves. *Oldenlandia humilis hyssopifolia.* Plum. Nov. Gen. *Dwarf Oldenlandia having a Hyssop leaf.*

This plant was discovered in America by Father Plumier, who gave this name to it in honour of Henry Bernard Oldenland, a German, who was disciple of Dr. Herman at Leyden, and was a very curious botanist.

The seeds of this plant were sent into England by Mr. Robert Millar, who gathered them in Jamaica. It is a low annual plant, which seldom rises above three or four inches high, and divides into many branches which spread near the ground. These branches are furnished with long narrow leaves, which are placed opposite. From the wings of the leaves arises the flower-stalk, which grows about an inch, or a little more in length, and divides into three or four smaller foot-stalks; on the top of each of these, stands one small white flower.

The seeds of this plant should be sown early in the spring on a hot-bed, and when the plants are come up, they should be transplanted on another hot-bed, or into small pots, and plunged into a moderate hot-bed of tanners bark, observing to water and shade them until they have taken root; after which time they must have a large share of free air in warm weather, and should be frequently refreshed with water. With this management the plants will flower in June, and their seeds will ripen in July, so that the seeds must be gathered from time to time as they ripen; for as the branches grow larger, so there will be fresh flowers produced until autumn, when the plants will perish; but if the seeds are permitted to scatter in the pots, the plants will soon after appear, which will live through the winter, provided they are placed in the stove, and will flower early the following spring.

OLEA. Tourn. Inst. R. H. 598. tab. 370. Lin. Gen. Plant. 20. [of *Ἑλαια*,] the Olive; in French, *Olivier*.

The CHARACTERS are,

It has a small tubulous empalement of one leaf, cut into four segments at the top. The flower consists of one petal which is tubulous, cut at the brim into four segments which spread open. It has two short stamina terminated by erect summits, and a roundish germen supporting a short style, crowned by a thick bifid stigma. The germen after-

OLE

ward turns to an oval smooth fruit (or berry) with one cell, inclosing an oblong oval nut.

This genus of plants is ranged in the first section of Linnaeus's second class, which contains those plants whose flowers have two stamina and one style.

The SPECIES are,

1. **OLEA** (*Gallica*) foliis lineari-lanceolatis subtus incanis. *Olive with linear spear-shaped leaves, which are hoary on their under side. Olea fructu oblongo minori.* Tourn. Inst. R. H. 599: *Olive with a smaller oblong fruit, commonly called Provence Olive.*

2. **OLEA** (*Hispanica*) foliis lanceolatis, fructu ovato. *Olive with spear-shaped leaves, and an egg-shaped fruit. Olea fructu maximo.* Tourn. Inst. R. H. 599. *Olive with the largest fruit, called the Spanish Olive.*

3. **OLEA** (*Sylvestris*) foliis lanceolatis obtusis rigidis, subtus incanis. *Olive with spear-shaped, obtuse, rigid leaves, which are hoary on their under side. Olea sylvestris, folio duro, subtus incano.* C. B. P. 472. *The wild Olive with a hard leaf, and hoary on its under side.*

4. **OLEA** (*Africana*) foliis lanceolatis lucidis, ramis teretibus. *Olive with spear-shaped shining leaves, and taper branches. Olea Afr. folio longo, lato, supra atroviridi splendente, infra pallide viridi.* Boer. Ind. alt. 2. 218. *African Olive, with a long, broad, shining leaf, of a greenish black above, and pale on its under side.*

5. **OLEA** (*Buxifolia*) foliis ovatis rigidis sessilibus. *Olive with oval stiff leaves, sitting close to the branches. Olea Afr. folio buxi crasso atroviridi, lucido, cortice albo scabro.* Boerh. Ind. alt. 2. 218. *African Olive, with a thick, dark, shining Box leaf; and a rough white bark, commonly called Box-leaved Olive.*

The first sort is what the inhabitants of the south of France chiefly cultivate, because from this species the best oil is made, which is a great branch of trade in Provence and Languedoc; and it is the fruit of this sort which is most esteemed when pickled: of this there are some varieties; the first is called Olive Picholine; there is another with dark green fruit, one with white fruit, and another with smaller and rounder fruit; but as these are supposed to be only accidental varieties which have risen from the same seeds, I have not enumerated them.

The Olive seldom rises to be a large tree, and is rarely seen with a single stem, but frequently two or three stems rise from the same root; these grow from twenty to thirty feet high, putting out branches from the sides almost their whole length, which are covered with a gray bark, and garnished with stiff leaves about two inches and a half long, and half an inch broad in the middle, gradually diminishing to both ends; they are of a lively green on their upper side, and hoary on their under, standing opposite. The flowers are produced in small bunches from the wings of the leaves; they are small, white, and have short tubes, spreading open at the top; these are succeeded by oval fruit, which, in warm countries, ripen in the autumn.

The second sort is chiefly cultivated in Spain, where the trees grow to a much larger size than the former sort; the leaves are much larger, and not so white on their under side; and the fruit is near twice the size of those of the Provence Olive, but are of a strong rank flavour, and the oil made from these, is too strong for most English palates.

The third sort is the wild Olive, which grows naturally in woods, in the south of France, Spain, and Italy, so is never cultivated; the leaves of this sort are much shorter and stiffer than those of the other; the branches are frequently armed with thorns, and the fruit is small and of no value.

The fourth and fifth sorts grow naturally at the Cape of Good Hope; the fourth rises to the height of the first, to which it bears some resemblance, but the bark is rougher; the leaves are not so long, and are of a lucid green on their upper side; but as this does not produce fruit in Europe, I can give no account of it.

The

The fifth sort is of humbler growth, seldom rising more than four or five feet high, sending out branches from the root upward, forming a bushy shrub; the branches are taper, and covered with a gray bark; the leaves are oval, very stiff, and smaller than those of the other species. This has not produced any fruit in England.

All these sorts are preserved in the gardens of the curious, but they are rather too tender to thrive in the open air, in the neighbourhood of London, where they are sometimes planted against walls, and with a little protection in very severe frost, they are maintained pretty well; but in Devonshire there are some of these trees, which have grown in the open air many years, and are seldom injured by the frost, but the summers are not warm enough to bring the fruit to maturity. There were several of these trees planted against a warm wall at Camden-house near Kensington, which succeeded very well, till their tops were advanced above the wall; after which they were generally killed in winter, so far down as to the top of the wall. These in 1719 produced a good number of fruit, which grew so large as to be fit for pickling; but since that time, their fruit has seldom grown to any size.

The Olive was, by the ancients, considered as a maritime tree, and they supposed it would not thrive at any distance from the sea; but by experience, we find they will succeed very well in any country, where the air is of a proper temperature of heat, though the trees are found to bear the spray of the sea better than most other sorts.

In Languedoc and Provence, where the Olive-tree is greatly cultivated, they propagate it by truncheons split from the roots of the trees; for as these trees are frequently hurt by hard frosts in winter, so when their tops are killed, they send up several stalks from the root; and when these are grown pretty strong, they separate them with an ax from the root, in the doing of which they are careful to preserve a few roots to the truncheons; these are cut off in the spring, after the danger of frost is over, and planted about two feet deep in the ground, covering the surface with litter or mulch, to prevent the sun and wind from penetrating and drying of the ground; when the plants have taken new root, they are careful to stir the ground and destroy the weeds.

This tree will grow in almost any soil, but when it is planted in rich moist ground, they grow larger and make a finer appearance, than in poor land; but the fruit is of less esteem, because the oil made from it is not so good as that which is produced in a leaner soil. The chalky ground is esteemed the best for these trees, and the oil which is made from the trees growing in that sort of land is much finer, and will keep longer than the other.

In the countries where the inhabitants are curious in the making of their oil, they are frequently obliged to get truncheons of the ordinary sorts of Olives to plant; but after they have taken good root, they graft them with the sort of Olive which they prefer to the others. In Languedoc they chiefly propagate the Cormeau, the Ampoulan, and Moureau, which are three varieties of the first species: but in Spain the second sort is generally cultivated, where they have more regard to the size of the fruit, and the quantity of oil they will produce, than to their quality. If the culture of these trees was well understood by the inhabitants of Carolina, and properly pursued, it might become a valuable branch of trade to them; for there is no reason to doubt of their succeeding, the summers there being hot enough to ripen the fruit to its utmost perfection.

In this country the plants are only preserved by way of curiosity, and are placed in winter in the greenhouse for variety, so I shall next give an account of the method by which they are here propagated, with their manner of treatment.

These plants may be propagated by laying down

their tender branches (in the manner practised for other trees,) which should remain undisturbed two years; in which time they will have put out roots, and may then be taken off from the old plants, and transplanted either into pots filled with fresh light earth, or into the open ground in a warm situation. The best season for transplanting is the beginning of April, when you should, if possible, take the opportunity of a moist season; and those which are planted in pots, should be placed in a shady part of the greenhouse until they have taken root; but those planted in the ground should have mulch laid about their roots, to prevent the earth from drying too fast, and now and then refreshed with water; but you must by no means let them have too much moisture, which will rot the tender fibres of their roots, and destroy the trees. When the plants have taken fresh root, those in the pots may be exposed to the open air, with other hardy exotics, with which they should be housed in winter, and treated as Myrtles, and other less tender trees and shrubs; but those in the open air will require no farther care until the winter following, when you should mulch the ground about their roots, to prevent the frost from penetrating deep into it; and if the frost should prove very severe, you should cover them with mats, which will defend them from being injured thereby; but you must be cautious not to let the mats continue over them after the frost is past, lest by keeping them too close, their leaves and tender branches should turn mouldy for want of free air; which will be of as bad consequence to the trees, as if they had been exposed to the frost, and many times worse; for it seldom happens, if they have taken much of this mould, or have been long covered, so that it has entered the bark, that they are ever recoverable again; whereas it often happens, that the frost only destroys the tender shoots; but the body and larger branches remaining unhurt, put out again the succeeding spring.

These trees are generally brought over from Italy every spring, by the persons who import Orange-trees, Jasmynes, &c. from whom they may be procured pretty reasonable; which is a better method than to raise them from layers in this country, that being too tedious; and those which are thus brought over, have many times very large stems, to which size young plants in this country would not arrive in ten or twelve years. When you first procure these stems, you should (after having soaked their roots twenty-four hours in water, and cleaned them from the filth they have contracted in their passage) plant them in pots filled with fresh light sandy earth, and plunge them into a moderate hot-bed, observing to screen them from the violence of the sun in the heat of the day, and also to refresh them with water, as you shall find the earth in the pots dry. In this situation they will begin to shoot in six weeks or two months after, when you should let them have air in proportion to the warmth of the season; and after they have made pretty good shoots, you should inure them to the open air by degrees, into which they should be removed, placing them in a situation where they may be defended from strong winds; in this place they should remain till October following, when they must be removed into the greenhouse, as was before directed. Having thus managed these plants until they have acquired strong roots, and made tolerable good heads, you may draw them out of the pots, preserving the earth to their roots, and plant them in the open air in a warm situation, where you must manage them as was before directed for the young ones; and these will in two or three years produce flowers, and in very warm seasons some fruit, provided they do well. The Lucca and Box-leaved Olives are the hardiest, for which reason they should be preferred to plant in the open air, but the first sort will grow to be the largest trees.

ONIONS. See CÉPA.

ONOBRYCHIS. See HEDYSARUM.

ONONIS. Lin. Gen. Plant. 772. Anonis. Tourn. Inst. R. H. 408. tab. 229. Rest-harrow, Cammock, Pettywin; in French, *Arrête-beuf*.

The CHARACTERS are,

The empalement of the flower is cut into five narrow segments, which end in acute points, the upper being a little raised and arched, the lower bending under the keel. The flower is of the butterfly kind. The standard is heart-shaped, depressed on the sides, and larger than the wings. The wings are oval and short; the keel is pointed, and longer than the wings. It hath ten stamina joined together, terminated by single summits, and an oblong hairy germen, supporting a single style, crowned by an obtuse stigma. The germen afterward becomes a turgid pod with one cell, inclosing kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. ONONIS (*Spinosa*) floribus subsessilibus, solitariis lateralibus, caule spinoso. Hort. Cliff. 389. Rest-harrow with single flowers sitting close to the sides of the branches, and a prickly stalk. Anonis spinosa flore purpureo. C. B. P. 389. Prickly Rest-harrow with a purple flower, sometimes called Cammock, or Petty-win, and in some countries, French *Kurze*.
2. ONONIS (*Mitis*) floribus subsessilibus solitariis lateralibus, ramis inermibus. Hort. Cliff. 359. Rest-harrow with single flowers sitting close to the stalks, and branches without spines. Anonis spinis carens purpurea. C. B. P. 389. Purple Rest-harrow having no spines.
3. ONONIS (*Repens*) caulibus diffusis, ramis erectis, foliis superioribus solitariis stipulis ovatis. Lin. Sp. 1006. Rest-harrow with diffused stalks, which are erect, the upper leaves single, and oval stipule. Anonis maritima procumbens, foliis hirsutis pubescentibus. Pluk. Alm. 33. Trailing maritime Rest-harrow with hairy leaves.
4. ONONIS (*Tridentata*) foliis ternatis carnosissublinearibus tridentatis, fruticosa pedunculis bifloris. Lin. Sp. Plant. 718. Shrubby Rest-harrow, with trifoliate fleshy leaves which are narrow, and have three indentures. Anonis Hispanica, frutescens, folio tridentato carnosissimo. Tourn. Inst. 408. Shrubby Spanish Rest-harrow with a fleshy leaf, having three indentures.
5. ONONIS (*Fruticosa*) fruticosa floribus paniculatis, pedunculis subtrifloris, stipulis vaginalibus, foliis ternatis lanceolatis serratis. Hort. Cliff. 358. Rest-harrow with paniculated flowers growing three upon a foot-stalk, sheath-like stipule, and trifoliate leaves. Anonis purpurea verna præcox frutescens, flore rubro amplo. Mor. Hist. 2. p. 170. Early spring, purple, shrubby Rest-harrow, with a large red flower.
6. ONONIS (*Natrix*) pedunculis unifloris aristatis foliis terminatis ovatis, stipulis integerrimis. Hort. Cliff. 358. Rest-harrow with one flower on a foot-stalk terminated by a thread, and oval trifoliate leaves. Anonis viscosa spinis carens lutea major. C. B. P. 389. Glutinous Rest-harrow without spines, having a large yellow flower.
7. ONONIS (*Viscosa*) pedunculis unifloris aristatis, foliis simplicibus infimis ternatis. Lin. Sp. 1009. Rest-harrow with one flower on each foot-stalk terminated by a thread, whose lower leaves are trifoliate. Anonis annua erectior, latifolia glutinosa Lusitanica. Tourn. Inst. 409. Annual broad-leaved, glutinous, erect Rest-harrow of Portugal.
8. ONONIS (*Minutissima*) floribus subsessilibus lateralibus, foliis ternatis glabris, stipulis setaceis, calycibus aristatis corolla longioribus. Lin. Sp. Plant. 1007. Rest-harrow with flowers sitting close to the sides of the stalks, trifoliate leaves, bristly stipule, and the beard of the calyx longer than the corolla. Anonis flore luteo parvo. H. R. Rar. Rest-harrow with a small yellow flower.

9. ONONIS (*Cristata*) pedunculis unifloris prælongis, ramis inermibus, foliis ternatis glabris, vaginis acutè dentatis. Rest-harrow with one flower growing on a long foot-stalk, branches without spines, smooth trifoliate leaves, and sheaths which are sharply indented. Anonis glabra inermis, pedunculis unifloris prælongis vaginis cristatis. Allion. Smooth Rest-harrow without spines, having one flower on a long foot-stalk, with a crested sheath.

10. ONONIS (*Ornithopodoides*) pedunculis bifloris aristatis, leguminibus linearibus cernuis. Prod. Leyd. 376. Rest-harrow with two flowers on a foot-stalk terminated by a thread, and narrow nodding pods. Anonis filiquis ornithopodii. Boerh. Ind. alt. 2. 34. Rest-harrow with pods like those of the Bird's-foot.

11. ONONIS (*Rotundifolia*) fruticosa pedunculis trifloris, calycibus triphylo-bractatis foliis ternatis subrotundis. Hort. Cliff. 358. Rest-harrow with foot-stalks proceeding from the side of the branches, sustaining three flowers, and trifoliate roundish leaves. Cicer sylvestre latifolium triphyllum. C. B. P. 347. Broad three-leaved wild Chick.

12. ONONIS (*Mitissima*) floribus sessilibus spicatis, bracteis stipularibus, ovatis ventricosis scariosis imbricatis. Lin. Sp. 1007. Rest-harrow with spiked flowers sitting close, and oval stipule to the flowers. Anonis alopecuroides, mitis annua purpurascens. Hort. Elth. 28. tab. 24. Smooth, annual, purplish, Fox-tail Rest-harrow.

13. ONONIS (*Alopecuroides*) spicis foliosis simplicibus ovatis obtusis stipulis dilatis. Lin. Sp. Plant. 1008. Rest-harrow with leafy spikes, and single obtuse leaves. Anonis sicula alopecuroides. Tourn. Inst. 408. Fox-tail Rest-harrow of Sicily.

14. ONONIS (*Anil*) foliis ternatis ovatis, petiolis longissimis, leguminibus hirsutis. Rest-harrow with oval trifoliate leaves growing on very long foot-stalks, and hairy pods. Anonis Americana, folio latiori subrotundo. Tourn. Inst. R. H. 409. American Rest-harrow with a broader roundish leaf.

15. ONONIS (*Decumbens*) foliis ternatis lineari-lanceolatis, caule decumbente, floribus spicatis alaribus, leguminibus glabris. Rest-harrow with trifoliate, narrow, spear-shaped leaves, a trailing stalk, flowers growing in spikes from the wings of the stalk, and smooth pods. Anonis Americana, angustifolia, humilior & minus hirsuta. Houst. MSS. Lower narrow-leaved American Rest-harrow, which is less hairy.

The first sort is a common weed in most parts of England, so is rarely admitted into gardens. It has a strong creeping root, which spreads far in the ground, and is with great difficulty eradicated; the stalks rise a foot and a half high, they are slender, purple, and hairy, sending out small branches on their side, which are armed with sharp prickles. The flowers come out singly from the side of the branches; they are of the butterfly kind, and of a purple colour, which are succeeded by small pods, containing one or two kidney-shaped seeds. It flowers great part of summer, and the seeds ripen in the autumn. The root of this is one of the five opening roots; the cortical part of it is esteemed a good medicine for stoppage of urine, and to open the obstructions of the liver and spleen; there is a variety of this with white flowers.

The second sort grows naturally in many parts of England, and has been by some supposed to be only a variety of the first; but I have cultivated both by seeds, and have always found the plants retain their difference; the stalks of this sort are hairy, and more diffused than those of the first; the leaves are broader, and sit closer on the branches; the stalks do not grow so upright, and have no spines; the flowers and pods are like those of the first. There is also a variety of this with white flowers.

The third sort grows naturally on the borders of the sea in several parts of England; this hath a creeping root, from which arise many hairy stalks which are near two feet long, spreading on every side upon the ground, garnished with trifoliate hairy leaves, those on the lower part of the stalks being pretty large and

oval, but the upper are smaller and narrower. The flowers are like those of the first in shape, coming out singly from the side of the stalks, but are of a brighter purple colour; the pods are short, containing two or three seeds in each. It flowers in July, and the seeds ripen in autumn.

The fourth sort grows naturally in Spain and Portugal; this rises with shrubby stalks a foot and a half high, dividing into slender branches very full of joints, garnished with narrow, trifoliate, thick, fleshy leaves, standing upon short foot-stalks. The flowers are produced at the end of the branches in loose panicles, some of the foot-stalks sustaining two, and others but one flower; they are of a fine purple colour, and appear in June; the seeds ripen in September.

The fifth sort grows naturally on the Alps: this is a very beautiful low shrub; it rises with slender shrubby stalks about two feet high, dividing into many branches, which are garnished with narrow trifoliate leaves sawed on their edges, sitting close to the branches. The flowers come out in panicles at the end of the branches upon long foot-stalks, which for the most part sustain three large purple flowers; the stipula is a kind of sheath, embracing the foot-stalk of the flower. It flowers the end of May and the beginning of June, and the flowers are succeeded by turgid pods about an inch long, which are hairy, inclosing three or four kidney-shaped seeds, which ripen in August. The sixth sort grows naturally in the south of France and in Spain; this hath a perennial root and an annual stalk, which rises near two feet high, sending out short branches from the side on the lower part of the plants, garnished with trifoliate oblong leaves, which are hairy and clammy. The flowers grow in loose spikes at the end of the stalks; they are large, and of a bright yellow colour, standing upon pretty long foot-stalks, which are extended beyond the leaves, the flowers hanging downward from the middle of the foot-stalk. The flowers appear the latter end of June, which are succeeded by turgid pods an inch long, containing three or four brown kidney-shaped seeds, which ripen in September.

The seventh sort grows naturally in Portugal, from whence the seeds were sent to me. This is an annual plant, with a strong, herbaceous, hairy stalk, rising a foot and a half high, sending out branches the whole length, closely garnished with trifoliate leaves; the middle lobe being large and oval, the two side lobes long and narrow, rounded at their points and indented on their edges; they are very clammy. The foot-stalks of the flowers come out from the wings of the stalks singly, each sustaining one pale yellow flower, standing erect in the middle of the foot-stalk, which is extended beyond the flower. This plant flowers in July, and the seeds ripen in autumn.

The eighth sort grows naturally in the south of France and Italy; this is an annual plant; the stalks rise about nine inches high, sending out one or two side branches toward the bottom; the leaves are small, trifoliate, and oval, standing upon pretty long foot-stalks, and are indented on their edges. The flowers come out singly at the wings of the stalk; they are small, yellow, and sit very close to the stalk, having a sharp bristly stipula under the empalement; the pods are very short and turgid, containing two or three kidney-shaped seeds. It flowers in July, and the seeds ripen in the autumn.

The ninth sort grows naturally on the Alps; this hath a perennial root, from which come out several slender trailing stalks about six inches long, garnished with small, trifoliate, oval leaves, indented on their edges, standing upon pretty short foot-stalks. The flowers come out singly toward the top of the stalk, upon pretty long slender foot-stalks, arising from the wings of the leaves, each sustaining one yellow flower; the sheath embracing the base of the foot-stalk, is sharply indented. This flowers in June, and the seeds ripen in the autumn.

The tenth sort grows naturally in Sicily, and is an

annual plant; the stalks rise about nine inches high, sending out one or two branches toward the bottom, garnished with small trifoliate leaves, which stand on short foot-stalks. The flowers come out from the side of the branches upon short foot-stalks, each sustaining two small yellow flowers, which are succeeded by jointed compressed pods like those of Bird's-foot, having four or five kidney-shaped seeds in each. This sort flowers in July, and the seeds ripen in the autumn.

The eleventh sort grows naturally on the Alps and Helvetian mountains; this rises with a single jointed stalk a foot and a half high, garnished with oval, indented, trifoliate leaves, standing on pretty long foot-stalks. The foot-stalks of the flowers come out from the wings of the leaves; they are long, slender, each sustains three pale yellow flowers, which are succeeded by short turgid pods, containing two or three seeds in each. It flowers in June, and the seeds ripen in September.

The twelfth sort came up in earth which was brought from Barbadoes, but it does not seem to be a native of that country, for it rises easily from seeds in the open air here, and perfects its seeds in the autumn, nor will it thrive in greater warmth. This hath an upright stalk a foot and a half high, sending out small side branches, which are garnished with roundish trifoliate leaves sawed on their edges, standing upon short foot-stalks. The flowers grow in short leafy spikes at the end of the branches; they are small, and of a pale purple colour, appearing in July, and are succeeded by short turgid pods, containing two or three kidney-shaped seeds, which ripen in the autumn. The thirteenth sort grows naturally in Portugal, Spain, and Italy. This is an annual plant, rising with upright branching stalks a foot high, garnished with single leaves sitting close to the stalks; the larger leaves are oval, about one inch long and three quarters of an inch broad; the upper leaves are narrow, ending in obtuse points, and are slightly indented at their ends. The flowers grow in leafy spikes at the end of the stalks set close together, having hairy empalements; they are pretty large, of a purple colour, and appear in July: these are succeeded by taper pods about an inch long, inclosing four or five kidney-shaped seeds. This plant has several titles, in the different books of botany.

The fourteenth sort grows naturally in the American islands; this is an annual plant, rising with a branching stalk two feet high, garnished with trifoliate leaves, whose lobes are oval, standing upon very long foot-stalks, which are hairy. The flowers grow in loose spikes at the end of the branches; they are large, and of a purplish yellow colour, and are succeeded by very turgid hairy pods, each containing five or six large kidney-shaped seeds. This sort flowers in July and August, and the seeds ripen in the autumn. From this plant Indigo was formerly made, which, I suppose, was of less value than that which is made of Anil, so has not been for many years past cultivated in any of the islands.

The fifteenth sort was discovered by the late Dr. Houstoun, growing naturally at La Vera Cruz in New Spain, from whence he sent the seeds to England. This is a perennial plant, from whose roots come out several pretty strong branches, which spread and incline toward the ground; these are garnished with narrow trifoliate leaves, very little hairy. The flowers come out in loose panicles at the end of the branches; they are yellow, and are succeeded by smooth turgid pods about half an inch long, each containing two or three kidney-shaped seeds. This flowers in July, and the seeds sometimes ripen here in the autumn.

The three first sorts are never cultivated in gardens, being very troublesome weeds whenever they get into the fields; for the roots spread and multiply greatly in the ground, and are so tough and strong, that the plough will scarcely cut through them; so are with great difficulty eradicated when they have once gotten possession.

The

The fourth and fifth sorts are low shrubby plants, which are propagated by seeds. The fourth is too tender to thrive in the open air in England, unless it is planted in a warm situation, and in very severe frost covered to protect it. If the seeds of both these sorts are sown upon a bed of light earth in April, the plants will come up in May, when they must be kept clean from weeds; and if they are too close, some of them should be carefully drawn up in moist weather, and transplanted at four or five inches distance: those of the fourth sort upon a warm sheltered border, but the fifth may be planted in a shady border, where they will thrive very well; after these have taken root, the plants will thrive very well, but must be kept clean from weeds till the following autumn, when they may be transplanted to the places where they are to remain; those plants which were left growing in the bed where they were sown, must also be treated in the same way. These plants will not thrive in pots, therefore should always be planted in the full ground, where the fifth sort will flourish greatly, and frequently send up many plants from their roots, but the other is more impatient of cold. These plants will flower the second year, and make a fine appearance during the continuance of their flowers, and the fifth sort will produce seeds in plenty.

The sixth sort is propagated by seeds, which should be sown thin in drills upon a bed of light earth; and when the plants come up, they must be kept clean from weeds till the autumn, when they should be carefully taken up, and transplanted into the borders of the pleasure-garden, where they are to remain; the second year they will flower and produce ripe seeds, but the roots will continue several years, and are very hardy.

The seventh, eighth, and eleventh sorts are hardy annual plants; these are propagated by seeds, which should be sown in the places where the plants are to remain, and will require no other care but to thin them where they are too close, and keep them clean from weeds.

The ninth sort is a hardy perennial plant, but as it makes but little appearance, so it is rarely preserved, unless in botanic gardens for the sake of variety; it rises yearly from seed, and will thrive in any soil or situation.

The fourteenth sort is an annual plant; the seeds of this must be sown upon a moderate hot-bed in the spring, and, when the plants are fit to remove, they should be transplanted to another moderate hot-bed to bring the plants forward, treating them in the same way as the African and French Marygold. In June they should be taken up with balls of earth to their roots, and transplanted into the open borders, where, if they are shaded till they have taken root, they will thrive and flower the following month, and perfect their seeds in autumn.

The eighteenth sort is a tender plant. The seeds of this should be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a small pot filled with light loamy earth, and plunged into a hot-bed of tanners bark, observing to shade them from the sun till they have taken new root, after which they must be treated in the same way as other tender plants from the same countries. In autumn they should be removed into the bark-stove; the summer following they will produce flowers, but they do not often perfect seeds in England.

ONOPORDUM. Lin. Gen. Plant. 834. Vaill. Act. Par. 1718. Carduus. Tourn. Inst. R. H. 440. tab. 253. Woolly Thistle; in French, *Chardon*.

The CHARACTERS are,

The common empalement is roundish, bellied, and imbricated, composed of numerous scales terminated by spines. The flower is composed of many hermaphrodite florets, which are funnel-shaped, equal, and uniform, having narrow tubes swelling at the brim, cut into five points; they have five short hairy stamina, terminated by cylindrical summits, and an oval germen crowned with down,

supporting a slender style terminated by a crowned stigma. The germen becomes a single seed crowned with down, fitting in the empalement.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, which includes those plants with compound flowers, whose florets are all hermaphrodite and fruitful.

The SPECIES are,

1. **ONOPORDUM** (*Acanthium*) *calycibus squarrosis, foliis ovato-oblongis sinuatis.* Lin. Sp. Plant. 827. *Woolly Thistle with rough empalements, and oblong, oval, sinuated leaves.* Carduus tomentosus, acanthi folio, vulgaris. Tourn. Inst. R. H. 441. *Common Woolly Thistle with a Bearsbreech leaf.*
2. **ONOPORDUM** (*Illyricum*) *calycibus squarrosis, spinis foliis lanceolatis pinnatifidis.* Lin. Sp. Plant. 1158. *Woolly Thistle with rough empalements, and narrow leaves ending in many points.* Carduus tomentosus, acanthi folio angustiori. Tourn. Inst. R. H. 441. *Woolly Thistle with a narrower Bearsbreech leaf.*
3. **ONOPORDUM** (*Arabicum*) *calycibus imbricatis.* Hort. Upsal. 249. *Woolly Thistle with imbricated empalements.* Carduus tomentosus, acanthi folio altissimus, Lusitanicus. Tourn. Inst. 441. *Tallest woolly Thistle of Portugal, with a Bearsbreech leaf.*
4. **ONOPORDUM** (*Oriente*) *calycibus squarrosis, foliis oblongis pinnato-sinuatis decurrentibus, capite magno.* *Woolly Thistle with rough empalements, oblong, sinuated, wing-pointed leaves running along the stalk, and a large head.* Carduus tomentosus, acanthi folio Aleppicus, magno flore. Tourn. Inst. R. H. 441. *Woolly Thistle of Aleppo with a Bearsbreech leaf, and a large flower.*
5. **ONOPORDUM** (*Acaulon*) *tubacaule.* Lin. Sp. 1159. *Woolly Thistle with a head sitting close to the ground.* Onopordon acaulon ferme flore albicante. D. Jussieu. Vaill. Mem. 1718. *Woolly Thistle without a stalk, and having a whitish flower.*

There are some other species of this genus, which are preserved in botanic gardens, and also several varieties differing in the colours of their flowers; but as these plants are rarely admitted into other gardens, so it would be to little purpose to enumerate them here.

The first sort grows naturally on uncultivated places in most parts of England. It is a biennial plant; the first year it puts out many large downy leaves, which are sinuated on their edges, and are prickly; these spread on the ground, and continue the following winter, and in the spring arises the stalk in the middle of the leaves, which, upon dunghills, or good ground, grows five or six feet high, dividing upward into many branches, which have leafy borders running along them, indented, and each indenture is terminated by a spine. The stalks are terminated by scaly heads of purple flowers, which appear in June, and to these succeed oblong angular seeds crowned with a hairy down, which assist their spreading about to a great distance by the wind, so that where the plants are permitted to ripen their seeds, they often become troublesome weeds.

The second sort grows naturally in Spain, Portugal, and the Levant; this rises with a taller stalk than the former, the leaves are much longer and narrower, and the indentures on their sides are regular, ending in sharp spines. The heads of flowers are larger, and the spines of the empalement are longer than those of the first sort.

The third sort grows to the height of nine or ten feet; the stalks divide into many branches; the leaves are longer than any of the other species; the heads of flowers are large and of a purple colour; the empalement hath the scales lying over each other like the scales of fish. This grows naturally in Spain and Portugal.

The fourth sort grows naturally about Aleppo; this rises with an upright branching stalk seven or eight feet high; the leaves are long and are regularly sinuated on their borders, like wing-pointed leaves; the heads of the flowers are very large, and the empalement is very rough and prickly.

The

The fifth sort hath several oblong, oval, woolly leaves, which spread on the ground; between these comes out the head of flowers sitting close to the ground; these heads are smaller than any of the other, and the flowers are white. Some of these plants have been formerly cultivated for the table, but it was before the English gardens were well supplied with other ciculent plants, for at present they are rarely eaten here. They require no culture, for if the seeds are permitted to fall, the plants will come up fast enough.

ONOSMA. Lin. Gen. 187.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is erect, and cut into five segments; the corolla is bell-shaped, of one petal, having a short tube, with a swelling top, the brim cut into five parts, and naked pervious chaps; it hath five short awl-shaped stamens, terminated by arrow-shaped summits, which are the length of the corolla, and a germen of four parts, supporting a slender style, crowned by an obtuse stigma; the germen afterward becomes four seeds sitting in the empalement.

This genus of plants is ranged in the first section of Linnæus's fifth class, intitled Pentandria Monogynia, the flowers having five stamens and one style.

The SPECIES are,

1. ONOSMA (*Simplicissima*) foliis confertissimis lanceolato-linearibus pilosis. Lin. Sp. 196. *Onosma with hairy, linear, spear-shaped leaves growing in clusters.* Echium Creticum. Alp. Exot. 130. *Cretan Viper's Bugloss.*
2. ONOSMA (*Orientalis*) foliis lanceolatis hispidis, fructibus pendulis. Lin. Sp. 196. *Onosma with hispid spear-shaped leaves, and hanging fruit.* Cerinthe Orientalis. Amœn. Acad. 4. p. 267. *Eastern Honeywort.*
3. ONOSMA (*Eckiioides*) foliis lanceolatis hispidis, fructibus erectis. Lin. Sp. 196. *Onosma with hispid spear-shaped leaves and erect fruit.* Anchusa lutea minor. C. B. P. 255. *Smaller yellow Bugloss.*

The first and second sorts are generally biennial plants, which perish soon after they have perfected seeds; though sometimes when they happen to grow out of the joints of walls, or the fissures of rocks, they will abide three or four years; for in such situations the plants are stunted in their growth, so are less replete with moisture, and more compact, whereby they are in less danger of suffering from frost in winter. Therefore, if all the three sorts can be cultivated on a wall or in rubbish, where their seeds may scatter, they may be maintained much better than in good ground. In order to have the plants grow in such situations, it will be proper to sow their seeds soon after they are ripe, either on the joints of old walls, or in rubbish, laying the stalks of the plants over the places where their seeds are sown, which will shade them from the sun, and thereby greatly forward the vegetation of the seeds; and when the plants are well established in their situation, if they are permitted to scatter their seeds, they will maintain themselves very well afterwards.

As these plants are seldom cultivated unless in botanic gardens, so it will be unnecessary to enlarge farther about them; they flower early in the spring, and their seeds ripen in June.

OPHIOGLOSSUM, Adder's-tongue.

This plant grows naturally in moist meadows, and is not easily brought to thrive long in gardens, so is rarely attempted.

OPHRYS. Tourn. Inst. R. H. 437. tab. 250. Lin. Gen. Plant. 902. Twyblade.

The CHARACTERS are,

It has a single stalk with a vague spathe (or sheath.) The flower hath no empalement; it consists of five oblong petals which ascend, and join so as to form a helmet, and the under one is bifid. The nectarium is dependent, and keel-shaped behind; it hath two short stamens sitting on the pointal, with crest summits fastened to the interior border of the nectarium, and an oblong contorted germen situated under the flower, with a style adbering to the inner border of the nectarium, crowned by an obsolete stigma. The germen afterward turns to an oval, three-cor-

nered, obtuse capsule, with one cell opening with three valves, and filled with small seeds like dust.

This genus of plants is ranged in the first section of Linnæus's twentieth class, which contains the plants whose flowers have two stamens, which are joined to the style; he has joined to this genus several species of Orchis.

The SPECIES are,

1. OPHRYS (*Nidas avis*) bulbis fibroso-fasciculatis caule vaginato, nectarii labio bifido. Lin. Sp. Plant. 1339. *Twyblade with a fibrous root bundled, and a bifid lip to the nectarium.* Ophrys bifolia. C. B. P. 87. *Common Twyblade, or Twyblade.*
2. OPHRYS (*Cordato*) bulbo fibroso, caule bifolio, foliis cordatis. Lin. Sp. Plant. 946. *Twyblade with a fibrous root, and two heart-shaped leaves on the stalk.* Ophrys minima. C. B. P. 87. *Smallest Twyblade.*
3. OPHRYS (*Spiralis*) bulbis aggregatis oblongis, caule subfolioso, floribus secundis, nectarii labio indiviso. Act. Upsal. 1740. *Twyblade with oblong clustered bulbs, a leafy stalk, fruitful flowers, and an undivided lip to the nectarium.* Orchis spiralis alba odorata. J. B. 2. 769. *White, sweet-scented, spiral Orchis, called Triple Ladies Traces.*
4. OPHRYS (*Monorchis*) bulbo globoso, caule nudo, nectarii labio trifido. Act. Upsal. 1740. *Twyblade with a globular bulb, a naked stalk, and a trifid lip to the nectarium.* Orchis odorata moschata, five monorchis. C. B. P. 84. *Yellow, sweet, or Musk Orchis.*
5. OPHRYS (*Anthropophora*) bulbis subrotundis, scapo folioso, nectarii labio lineari tripartito, medio elongato bifido. Lin. Sp. Plant. 948. *Twyblade with roundish bulbs, a leafy stalk, and a narrow three-pointed lip to the nectarium, the middle segment of which is stretched out and bifid.* Orchis flore nudi hominis effigiem representans foemina. C. B. P. 82. *Man Orchis.*
6. OPHRYS (*Insectifera*) bulbis subrotundis, scapo folioso, nectarii labio subquinelobo. Lin. Sp. Plant. 948. *Twyblade with roundish bulbs, a leafy stalk, and the lip of the nectarium divided almost into five lobes.* Orchis muscam referens major. C. B. P. 83. *Greater Fly Orchis.*
7. OPHRYS (*Adrachnites*) bulbis subrotundis, caule folioso, nectarii labio trifido. *Twyblade with roundish bulbs, a leafy stalk, and a trifid lip to the nectarium.* Orchis fucum referens major, foliolis superioribus candidis, aut purpurascens. C. B. P. 83. *The common Humble Bee Orchis.*
8. OPHRYS (*Sphegodes*) bulbis subrotundis, caule subfolioso, nectarii labio trifido hirsuto. *Twyblade with roundish bulbs, a leafy stalk, and a hairy trifid lip to the nectarium.* Orchis five testiculus sphegodes hirsuto flore. J. B. 2. 727. *Humble Bee Satyrion with green wings.*

The first sort grows naturally in woods, and sometimes in moist pastures in several parts of England. The root is composed of many strong fibres, from which arise two oval veined leaves three inches long, and two broad, joined at their base; between these arises a naked stalk about eight inches high, terminated by a loose spike of herbaceous flowers, resembling gnats, composed of five petals, with a long bifid lip to the nectarium, with a crest or standard above, and two wings on the side. The flowers sit upon an angular germen, which afterward swells to a capsule, opening when ripe in six parts, and filled with small dusty seeds. This plant refuses culture, but may be transplanted from the places where it grows naturally, into a shady part of the garden, where, if the roots are not disturbed, they will continue several years, and flower in May, but they do not increase in gardens. The best time to remove the roots is in July or August, when the leaves are decaying, for it will be difficult to find the roots after the leaves are gone.

The second sort is found in some of the northern counties in England, but is seldom seen growing in the south. This hath a small bulb with many strong fibres to the root, and sends out two small, ribbed, heart-shaped leaves at bottom. The stalk rises about four inches high, and is terminated by a spike of small herbaceous flowers shaped like those of the first sort.

The

The third sort grows upon chalky hills in several parts of England; this hath an oblong, clustered, bulbous root, from which arises a single stalk six inches high, having two oblong leaves at bottom, and rarely any above; the flowers are small, of a white colour, growing in a loose spike on the top of the stalk; they have a musky scent. This flowers in August.

This sort grows naturally in moist pastures in the northern parts of England; I have also found it in great plenty on Enfield Chace, not far from the town.

The fourth and fifth sorts grow upon the chalk-hills near Northfleet in Kent, and also upon Causham-hills near Reading; they have roundish bulbous roots, from which come out a few oblong leaves; the stalks rise a foot and a half high, garnished with a few narrower leaves; the flowers grow in a loose spike on the top of the stalk; they are in one of a rusty iron colour, and the other hath herbaceous flowers. The lip of the nectarium is divided into three parts, the middle segment being stretched out much longer than the other, and is divided into two; the upper part of the flower being hooded, the whole bears some resemblance to a naked man. They flower in June.

The eighth sort grows naturally in dry pastures in several parts of England, and is commonly called the Humble Bee Orchis; of this there are two or three varieties found wild in England, and several more in Spain and Portugal. This hath a roundish bulbous root; the leaves are like those of the narrow-leaved Plantain. The stalk rises six or seven inches high, having two or three sheath-shaped leaves embracing it, which are erect; at the top of the stalk come out two or three flowers without spurs, having purplish crests and wings. The nectarium is large, shaped like the body of a humble bee, of a dark sooty colour, with two or three lines running across it of a darker or lighter colour, which appear brighter or duller according to the position of the flower to the sun. It flowers early in June. There are some varieties of this sort, which differ in the colour and size of their flowers.

All these sorts may be preserved in gardens, though not propagated there. The best time to remove the roots from the places where they naturally grow, is just before the stalks fall, for at that time the roots may be easily discovered, and then they are beginning to rest, so that the bulb will be fully formed for flowering the following year, and will not shrink; but when they are removed at a time of the year when they are in action, the bulb designed for flowering the following year, not being fully ripened, will shrink, and frequently perish; or if they survive their removal, do not recover their former strength in less time than two years.

When these are removed into a garden, the soil should be adapted to the sorts. Such of them as grow naturally in moist pastures, should be planted in shady moist borders; those which are inhabitants of woods may be planted under trees in wildernesses, but such as grow upon chalk-hills should have a bed of chalk prepared for them in an open situation, and when the plants are fixed in their several places, they should not be disturbed after; for if they are kept clean from weeds, the less the ground is disturbed, the better the plants will thrive, and the longer they will continue.

OPUNTIA. Tourn. Inst. R. H. 239. tab. 122. Tuna. Hort. Elth. 295. Cactus. Lin. Gen. Plant. 539. [This plant is called Opuntia, because Theophrastus writes, that it grows about Opuntium.] The Indian Fig, or prickly Pear; in French, *Raquette*.

The CHARACTERS are,

The flower is composed of several petals, which are obtuse, concave, and placed in a circular order, sitting upon the germen. It has a great number of awl-shaped stamina, which are inserted in the germen, are shorter than the petals, and terminated by oblong erect summits. The germen, which is situated under the flower, supports a cylindrical style the length of the stamina, crowned by a multifid stigma. The germen afterward turns to a fleshy

umbilicated fruit with one cell; inclosing many roundish seeds.

This genus of plants is ranged in the second section of Tournefort's sixth class, which includes the herbs with a Rose flower, whose pointal or empalement becomes a fruit with one capsule. Dr. Linnæus places it in the first section of his twelfth class, in which he ranges those plants whose flowers have more than nineteen stamina, which are inserted either into the empalement, or petals of the flower.

The SPECIES are,

1. OPUNTIA (*Vulgaris*) articulis ovatis compressis, spinis setaceis. Indian Fig with oval compressed joints, and bristly spines. Opuntia vulgò herbariorum. J. B. 1. 154. The common Opuntia, or Indian Fig.
2. OPUNTIA (*Ficus Indica*) articulis ovato-oblongis, spinis setaceis. Indian Fig with oblong oval joints, and bristly spines. Opuntia folio oblongo media. Tourn. Inst. R. H. 239. Middle Indian Fig with oblong leaves.
3. OPUNTIA (*Tuna*) articulis ovato-oblongis, spinis subulatis. Indian Fig with oblong oval joints, and awl-shaped spines. Opuntia major, validissimis spinis munita. Tourn. Inst. R. H. 239. Greater Indian Fig with very strong spines.
4. OPUNTIA (*Elatior*) articulis ovato-oblongis, spinis longissimis nigricantibus. Indian Fig with oblong oval joints, and very long black spines. Tuna elatior spinis validis nigricantibus. Hort. Elth. tab. 194. Taller Indian Fig with strong black spines.
5. OPUNTIA (*Maxima*) articulis ovato-oblongis crassissimis, spinis inæqualibus. Indian Fig with oblong, oval, thick joints, and unequal spines. Opuntia maxima, folio spinoso, latissimo & longissimo. Tourn. Inst. 240. Greatest Indian Fig, with the longest and broadest prickly branches.
6. OPUNTIA (*Cochinelifera*) articulis ovato-oblongis subinermibus. Indian Fig with oblong oval joints, almost without spines. Opuntia maxima, folio oblongo-rotundo majore, spinulis mollibus & innocentibus obsito, flore striis rubris variegato. Sloan. Cat. Jam. 194. Greatest Indian Fig, with a larger, oblong, round leaf, armed with soft, innocent, small spines, and a flower variegated with red stripes, commonly called the Cochineal Fig.
7. OPUNTIA (*Curassavica*) articulis cylindrico-ventricosus, compressis, spinis setaceis. Indian Fig with compressed, cylindrical, bellicd joints, and bristly spines. Ficus Indica, seu Opuntia Curassavica minima. Hort. Amst. 1. 107. Indian Fig, or the least Opuntia of Curassoa, frequently titled Pinpillow.
8. OPUNTIA (*Spinosissima*) articulis longissimis tenuibus compressis, spinis longissimis confertissimis, gracilibus albicantibus armatis. Houst. MSS. Stalky Indian Fig, with large, narrow, compressed leaves, armed with the longest, narrowest, white spines, growing in clusters; this is by the gardeners called, *Robinson Crusoe's Coat*.
9. OPUNTIA (*Phyllanthus*) prolifer ensiformi-compressus serrato-repandus. Indian Fig with compressed sword-shaped joints, whose indentures turn backward. Cereus scolopendri folio brachiato. Hort. Elth. 73. tab. 64. Torch Thistle with a branching Spleenwort leaf.

These plants are all of them natives of America, though the first sort is found growing wild on the sides of the roads about Naples, in Sicily, and Spain, but it is probable that the plants may have been brought from America thither at first. This sort has been long in the English gardens; the joints or branches of this are oval, or roundish, compressed on their two sides flat, and have small leaves coming out in knots on their surface, as also on their upper edges, which fall off in a short time; and at the same knots there are three or four short bristly spines, which do not appear unless they are closely viewed; but on being handled, they enter the flesh, and separate from the plant, so are troublesome, and often very difficult to get out of the flesh. The branches of this sort spread near the ground, and frequently trail upon it, putting out new roots, so are extended to a considerable distance, and never rise in height; these are fleshy and herbaceous while they are young,

but as they grow old become drier, of a tough texture, and have ligneous fibres. The flowers come out on the upper edges of the branches, generally, though sometimes they are produced on their sides; these sit upon the embryo of their fruit, and are composed of several roundish concave petals, which spread open; they are of a pale yellow colour, and within arise a great number of stamina, fastened to the embryo of the fruit, which are terminated by oblong summits; and in the center is situated the style, crowned by a many-pointed stigma; after the flowers are past, the embryo swells to an oblong fruit, whose skin, or cover, is set with small spines in clusters, and the inside is fleshy, of a purple, or red colour, in which are lodged many black seeds. This plant flowers here in July and August, but unless the season is very warm, the fruit will not ripen in England.

I received some branches of this sort from Mr. Peter Collinson, F. R. S. who assured me they were sent him from Newfoundland, where the plants grow naturally, which is much farther to the north than it was before known to grow; and how it endures the cold of that country is inconceivable, for though the plants will live abroad in England, in a warm situation and a dry soil, yet, in severe winters, they are generally destroyed, if they are not protected from the frost.

The second sort hath oblong, oval, compressed branches, which grow more erect than those of the first, armed with long bristly spines, which come out in clusters from a point on each of the compressed sides, spreading open like the rays of a star. The flowers grow upon the embryo of the fruit, which come out from the upper edges of the leaves like the first, but are larger, and of a brighter yellow colour. The fruit is also larger, and of a deeper purple colour, the outer skin is also armed with longer spines; this is the most common sort in Jamaica, and upon the fruit of this the wild sort of cochineal feeds, which is called *Sylvester*. I had some of the plants sent me with the live insects upon them from Jamaica, by the late Dr. Houstoun, who was writing a history of these insects, at the time when he was taken ill and died; these insects kept alive upon the plants here for three or four months, but afterward perished. If the fruit of this plant is eaten, it will dye the urine of a bloody colour.

The third sort hath stronger branches than the second, which are armed with larger thorns, of an awl-shape; they are whitish, and come out in clusters like those of the other sort. The flowers are large, of a bright yellow colour, and the fruit is shaped like that of the second sort.

The fourth sort grows taller than either of the former; the branches are larger, thicker, and of a deeper green, and are armed with strong black spines, which come out in clusters like those of the other sorts, but the clusters are farther asunder. The flowers are produced from the upper edges of the branches; they are smaller than those of the other sorts, and are of a purplish colour, as are also the stamina; the fruit is of the same form as those of the first, but do not ripen here.

The fifth sort is the largest of all the sorts yet known. The joints of these are more than a foot long, and eight inches broad; they are very thick, of a deep green colour, and armed with a few short bristly spines; the older branches of this often become almost taper, and are very strong. The flowers of this sort I have never yet seen; for although I have had many of the plants more than ten feet high, none of them has produced any flowers.

The sixth sort has been always supposed to be the plant, upon which the cochineal insects feed; this hath oblong, smooth, green branches, which grow erect, and rise to the height of eight or ten feet, having scarce any spines on them and those few which are, can scarce be discerned at a distance, and are so soft as not to be troublesome when handled. The flowers of this sort are small, and of a purple colour,

standing upon the embryo of the fruit, in the same manner as those of the other sort, but do not expand open like them. The flowers of this appear late in the autumn, and the fruit drop off in winter, without coming to any perfection here; this sort is cultivated in the fields of New Spain, for the increase of the insects, but it grows naturally in Jamaica, where it is probable the true cochineal might be discovered; if persons of skill were to search after the insects.

The seventh sort is said to grow naturally at Curassao; this hath cylindrical swelling joints, which are closely armed with slender white spines. The branches spread out on every side, and where they have no support, fall to the ground, very often separating at the joints from the plants, and as they lie upon the ground, put out roots, so form new plants; this sort very rarely produces flowers in England. In the West-Indies it is called *Pinpillow*, from the appearance which the branches have to a pin-cushion stuck full of pins.

The eighth sort was sent me from Jamaica by the late Dr. Houstoun, who found it growing naturally there in great plenty, but could never observe either fruit or flower upon any of the plants, nor have any of them produced either in England. The branches of this sort have much longer joints than any of the other; they are narrower, and more compressed. The spines of this are very long, slender, and of a yellowish brown colour, coming out in clusters all over the surface of the branches, crossing each other, so as to render it dangerous to handle; for upon being touched, the spines adhere to the hand and quit the branches, and penetrate into the flesh, so become very troublesome.

The ninth sort grows naturally in the Brasils; this hath very thin branches, which are indented regularly on their edges, like *Spleenwort*; they are of a light green, and shaped like a broad sword; these are smooth, having no spines. The flowers come out from the side, and at the end of the branches, sitting on the embryos in the same way as the other sorts; they are of a pale yellow colour. The fruit is shaped like those of the first sort, but rarely ripen in England.

All these sorts (except the first) are too tender to thrive in the open air in England; nor can many of them be preserved through the winter here, unless they have artificial heat; for when they are placed in a green-house, they turn to a pale yellow colour, their branches shrink, and frequently rot on the first approach of warm weather in the spring.

These plants may be all propagated by cutting off their branches at the joints, during any of the summer months, which should be laid in a warm dry place for a fortnight, that the wounded part may be healed over, otherwise they will rot with the moisture which they imbibe at that part, as is the case with most other succulent plants. The soil in which these plants must be planted, should be composed after the following manner, viz. one third of light fresh earth from a pasture, a third part sea sand, and the other part should be one half rotten tan, and the other half lime rubbish; these should be well mixed, and laid in a heap three or four months before it is used, observing to turn it over at least once a month, that the several parts may be well united; then you should pass it through a rough screen, in order to separate the largest stones and clods, but by no means sift it too fine, which is a very common fault; then you should reserve some of the smaller stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off; which is what must be observed for all succulent plants, for if the moisture be detained in the pots, it will rot their roots and destroy the plants.

When you plant any of the branches of these plants (except the first sort) you should plunge the pots into a moderate hot-bed, which will greatly facilitate their taking root; you should also refresh them now and then with a little water, but be very careful not to let them

them have too much, or be too often watered, especially before they are rooted. When the plants begin to shoot, you must give them a large share of air, by raising the glasses, otherwise their shoots will draw up so weak, as not to be able to support themselves; and after they have taken strong root, you should inure them to the air by degrees, and then remove them into the stove where they should remain, placing them near the glasses, which should always be opened in warm weather; so that they may have the advantage of a free air, and yet be protected from wet and cold.

During the summer season these plants will require to be often refreshed with water, but it must not be given to them in large quantities lest it rot them, and in winter this should be proportioned to the warmth of the stove; for if the air be kept very warm they will require to be often refreshed, otherwise their branches will shrink; but if the house be kept in a moderate degree of warmth, they should have but little, for moisture at that season will rot them very soon. The heat in which these plants thrive best, is the temperate point, as marked on botanical thermometers, for if they are kept too warm in winter, it causes their shoots to be very tender, weak, and unsightly. Those sorts which are inclinable to grow upright, should have their branches supported with stakes, otherwise their weight is so great, that it will break them down.

These plants are by most people exposed to the open air in the summer season, but they thrive much better if they are continued in the stoves, provided the glasses be kept open, so that they may have free air; for when they are set abroad, the great rains which generally fall in summer, together with the unsettled temperature of the air in our climate, greatly diminish their beauty, by retarding their growth; and sometimes in wet summers they are so replete with moisture, as to rot in the succeeding winter; nor will those plants which are set abroad (I mean the tender sorts) produce their flowers and fruit in such plenty, as those which are constantly preserved in the house.

ORANGE. See AURANTIUM.

ORCHARD. In planting of an Orchard, great care should be had to the nature of the soil; and such sorts of fruits only should be chosen, as are best adapted to the ground designed for planting, otherwise there can be little hopes of their succeeding; and it is for want of rightly observing this method, that we see in many countries Orchards planted, which never arrive to any tolerable degree of perfection, the trees starving; and their bodies are either covered with Moss, or the bark cracks and divides, both which are evident signs of the weakness of the trees; whereas, if instead of Apples the Orchard had been planted with Pears, Cherries, or any other sort of fruit better adapted to the soil, the trees might have grown very well, and produced great quantities of fruit.

As to the position of the Orchard, (if you are at full liberty to chuse) a rising ground, open to the south-east, is to be preferred; but I would by no means advise planting upon the side of a hill, where the declivity is very great; for in such places the great rains commonly wash down the better part of the ground, whereby the trees would be deprived of proper nourishment; but where the rise is gentle, it is of great advantage to the trees, by admitting the sun and air between them, better than it can upon an entire level; which is an exceeding benefit to the fruit, by dissipating fogs and drying up the damps, which, when detained amongst the trees, mix with the air and render it rancid: if it be defended from the west, north, and east winds, it will also render the situation still more advantageous, for it is chiefly from those quarters that fruit-trees receive the greatest injury; therefore, if the place be not naturally defended from these by rising hills (which is always to be preferred,) then you

should plant large growing timber-trees at some distance from the Orchard, to answer this purpose.

You should also have a great regard to the distance of planting the trees, which is what few people have rightly considered; for if you plant them too close, they will be liable to blights; the air being hereby pent in amongst them, will also cause the fruit to be ill tasted, having a great quantity of damp vapours from the perspiration of the trees, and the exhalations from the earth mixed with it, which will be imbibed by the fruit, and render their juices crude and unwholesome.

Wherefore I cannot but recommend the method which has been lately practised by some particular gentlemen with very good success, and that is, to plant the trees fourscore feet asunder, but not in regular rows. The ground between the trees they plough and sow with Wheat and other crops, in the same manner as if it were clear from trees; and they observe their crops to be full as good as those quite exposed, except just under each tree, until they are grown large, and afford a great shade; and by thus ploughing and tilling the ground, the trees are rendered more vigorous and healthy, scarcely ever having any Moss, or other marks of poverty, and will abide much longer and produce better fruit.

If the ground in which you intend to plant an Orchard has been pasture for some years, then you should plough in the green sward the spring before you plant the trees; and if you will permit it to lie a summer fallow, it will greatly mend it, provided you stir it two or three times, to rot the sward of Grass, and prevent weeds growing thereon.

At Michaelmas you should plough it pretty deep, in order to make it loose for the roots of the trees, which should be planted thereon in October, provided the soil is dry; but if it be moist, the beginning of March will be a better season. The distance, if designed for a close Orchard, must not be less than forty feet, but the trees planted twice that distance will succeed better.

When you have finished planting the trees, you should provide some stakes to support them, otherwise the wind will blow them out of the ground; which will do them much injury, especially after they have been planted some time; for the ground in the autumn being warm, and for the most part moist, the trees will very soon push out a great number of young fibres; which, if broken off by their being displaced, will greatly retard the growth of the trees.

In the spring following, if the season should prove dry, you should cut a quantity of green sward, which must be laid upon the surface of the ground about their roots, turning the Grass downward, which will prevent the sun and wind from drying the ground, whereby a great expence of watering will be saved; and after the first year they will be out of danger, provided they have taken well.

Whenever you plough the ground betwixt these trees, you must be careful not to go too deep amongst their roots, lest you should cut them off, which would greatly damage the trees; but if you do it cautiously, the stirring the surface of the ground will be of great benefit to them; though you should observe, never to sow too near the trees, nor suffer any great rooting weeds to grow about them, which would exhaust the goodness of the soil, and starve them.

If after the turf which was laid round the trees be rotted, you dig it in gently about the roots, it will greatly encourage them.

There are some persons who plant many sorts of fruit together in the same Orchard, mixing the trees alternately; but this is a method which should always be avoided, for hereby there will be a great difference in the growth of the trees, which will not only render them unsightly, but also the fruit upon the lower trees ill tasted, by the tall ones overshadowing them; so that if you are determined to plant several sorts of fruit on the same spot, you should observe to place

place the largest growing trees backward, and so proceed to those of less growth, continuing the same method quite through the whole plantation; whereby it will appear at a distance in a regular slope, and the sun and air will more equally pass throughout the whole Orchard, that every tree may have an equal benefit therefrom; but this can only be practised upon good ground, in which most sorts of fruit-trees will thrive.

The soil of your Orchard should also be mended once in two or three years with dung, or other manure, which will also be absolutely necessary for the crops sown between; so that where persons are not inclinable to help their Orchards, where the expence of manure is pretty great, yet, as there is a crop expected from the ground besides the fruit, they will the more readily be at the charge upon that account.

In making choice of trees for an Orchard, you should always observe to procure them from a soil nearly a-kin to that where they are to be planted, or rather poorer; for if you have them from a very rich soil, and that wherein you plant them is but indifferent, they will not thrive well, especially for four or five years after planting; so that it is a very wrong practice to make the nursery where young trees are raised very rich, when the trees are designed for a middling or poor soil. The trees should be also young and thriving, for whatever some persons may advise to the contrary, yet it has always been observed, that though large trees may grow and produce fruit after being removed, they never make so good trees, nor are so long lived, as those which are planted while young.

These trees, after they are planted out, will require no other pruning, but only to cut out dead branches, or such as cross each other, which render their heads confused and unsightly: the pruning them too often, or shortening their branches, is very injurious; especially to Cherries and stone-fruit, which will gum prodigiously, and decay in such places where they are cut; and the Apples and Pears which are not of so nice a nature, will produce a greater quantity of lateral branches, which will fill the heads of the trees with weak shoots, whenever their branches are thus shortened; and many times the fruit is hereby cut off, which, on many sorts of fruit-trees, is first produced at the extremity of their shoots.

It may, perhaps, seem strange to some persons, that I should recommend the allowing so much distance to the trees in an Orchard, because a small piece of ground will admit of very few trees when planted in this method; but if they will please to observe, that when the trees are grown up, they will produce a great deal more fruit, than twice the number when planted close, and will be vastly better tasted; the trees when placed at a large distance, being never so much in danger of blighting as in close plantations, as hath been observed in Herefordshire, the great county for Orchards, where they find, that when Orchards are so planted or situated, that the air is pent up amongst the trees, the vapours which arise from the damp of the ground, and the perspiration of the trees, collect the heat of the sun, and reflect it in streams so as to cause what they call a fire-blast, which is the most hurtful to their fruits; and this is most frequent where the Orchards are open to the south sun. But as Orchards should never be planted, unless where large quantities of fruit are desired, so it will be the same thing to allow twice or three times the quantity of ground; since there may be a crop of grain of any sort upon the same place (as was before said,) so that there is no loss of ground; and for a family only it is hardly worth while to plant an Orchard, since a kitchen-garden well planted with espaliers, will afford more fruit than can be eaten while good, especially if the kitchen-garden be proportioned to the largeness of the family; and if cyder be required, there may be a large avenue of Apple-trees extended cross a neighbouring field, which will render it pleasant, and produce a great quantity of fruit; or there

may be some single rows of trees planted to surround fields, &c. which will fully answer the same purpose, and be less liable to the fire-blasts before-mentioned.

ORCHIS. Tourn. Inst. R. H. 431. tab. 248, 249. Lin. Gen. Plant. 900. [of ὄρχις, a testicle, because the root of this plant resembles the testicles of a man; or of ὀρίγω, to have an appetite after, on account of its being a provocative to venery: it is also called κυνοόρχις, of κυνός, a dog, and ὄρχις, a testicle.] Satyrion, or Fool-stones.

The CHARACTERS are,

It hath a single stalk with a vague sheath; it has no empalement. The flower hath five petals, three without and two within, which rise and join in a standard. The nectarium is of one leaf, fixed to the side of the receptacle, between the division of the petals. The upper lip is short and erect, the under large, broad, and spreading; the tube is pendulous, horn-shaped, and prominent behind. It hath two short slender stamina sitting upon the pointal, with oval erect summits fixed to the upper lip of the nectarium. It hath an oblong contorted germen under the flower, with a short style fastened to the upper lip of the nectarium, crowned by an obtuse compressed stigma. The germen afterward turns to an oblong capsule with one cell, having three keel-shaped valves, opening on the three sides, but joined at top and bottom, filled with small seeds like dust.

This genus of plants is ranged in the first section of Linnæus's twentieth class, which contains those plants whose flowers have two stamina, which are connected with, or fixed to the style.

The SPECIES are,

1. ORCHIS (*Morio*) bulbis indivisis, nectarii labio quadrifido crenulato, cornu obtuso. Aët. Upsal. 1740. *Orchis with undivided bulbs, the lip of the nectarium cut into four points which are slightly indented, and an obtuse horn. Orchis morio fœmina. C. B. P. 82. Common female Orchis.*
2. ORCHIS (*Mascula*) bulbis indivisis, nectarii labio quadrilobo crenulato, cornu obtuso, petalis dorsalis reflexis. Flor. Succ. 795. *Orchis with undivided bulbs, the lip of the nectarium having four lobes and an obtuse horn, and the backs of the petals reflexed. Orchis motio mas, foliis maculatis. C. B. P. 81. The male Orchis with spotted leaves.*
3. ORCHIS (*Bifolia*) bulbis indivisis, nectarii labio lanceolato integerrimo, cornu longissimo, petalis patentibus. Aët. Upsal. 1740. *Orchis with undivided bulbs, the lip of the nectarium entire and spear-shaped, a very long horn, and petals spreading very wide. Orchis alba bifolia minor, calcar oblongo. C. B. P. 83. Smaller, white two-leaved Orchis, with an oblong spur, or Butterfly Orchis.*
4. ORCHIS (*Militaris*) bulbis indivisis, nectarii labio quinquefido punctis scabro, cornu obtuso, petalis confluentibus. Aët. Upsal. 1740. *Orchis with undivided bulbs, a five-pointed lip to the nectarium, having rough spots, an obtuse horn, and petals running together. Orchis latifolia, hiantæ cucullo major. Tourn. Inst. R. H. 432. The Man Orchis.*
5. ORCHIS (*Pyramidalis*) bulbis indivisis, nectarii labio trifido æquali integerrimo, cornu longo, petalis sublancoatis. Aët. Upsal. 1740. *Orchis with undivided bulbs, an equal trifid lip to the nectarium, with a long horn, and spear-shaped petals. Orchis militaris, montana, spicâ rubente, conglomeratâ. Tourn. Inst. R. H. 432. Mountain military Orchis, with a reddish conglomerated spike.*
6. ORCHIS (*Latifolia*) bulbis subpalmatis rectis, nectarii cornu conico, labio trilobo, lateralibus reflexo, bracteis flore longioribus. Aët. Upsal. 1740. *Orchis with fruit, palmated, bulbous roots, a conical horn to the nectarium, the lip cut into three lobes, which are reflexed on the sides, and bractæ longer than the flowers. Orchis palmata pratensis, latifolia, longis calcaribus. C. B. P. 85. Broad-leaved, Meadow, banded Orchis, having a long spur.*
7. ORCHIS (*Maculata*) bulbis palmatis patentibus, nectarii cornu germinibus brevioribus, labio plano petalis dorsalis patulis. Aët. Upsal. 1740. *Orchis with banded*

banded spreading bulbs, the horn of the nectarium shorter than the germen, a plain lip, and the hinder part of the petals spreading. *Orchis palmata pratensis, maculata.* C. B. P. 85. *Meadow banded Orchis, with spotted leaves.*

8. *ORCHIS (Cornopica) bulbis palmatis, nectarii cornu, setaceo germinibus longiore, labio trifido, petalis duobus patentissimis.* Aët. Upsal. 1740. *Orchis with palmated bulbs, a bristly horn to the nectarium, which is longer than the germen, and a trifid lip.* *Orchis palmata minor, calcaribus oblongis.* C. B. P. 85. *Smaller palmated Orchis, with an oblong spur to the flower.*

9. *ORCHIS (Abortiva) bulbis fasciculatis filiformibus, nectarii labio ovato integerrimo.* Aët. Upsal. 1740. *Orchis with thread-like bulbs growing in bunches, and the lip of the nectarium oval and entire.* *Limidorum Austriacum.* Clus. Pan. 241. *Purple Bird's-nest.*

The first sort grows naturally in pastures in most parts of England. This hath a double bulbous root, with some fibres coming out from the top; it has four or six oblong leaves lying on the ground, which are reflexed. The stalk rises nine or ten inches high, having four or six leaves which embrace it; this is terminated by a short loose spike of flowers, having a four-pointed indented lip to the nectarium, and an obtuse horn. The flowers are of a pale purple colour, marked with deeper purple spots; it flowers in May.

The second sort grows naturally in woods and shady places in many parts of England; this hath a double bulbous root, which is about the size and shape of middling Olives; it hath six or seven long broad leaves, shaped like those of Lilies, which have several black spots on their upper side; the stalk is round, and a foot high, having one or two smaller leaves embracing it. The flowers are disposed in a long spike on the top of the stalk; they are of a purple colour, marked with deep purple spots, and have an agreeable scent. It flowers the latter end of April.

The third sort grows naturally under the bushes by the side of pastures, in many parts of England. This hath a root composed of two oblong Pear-shaped bulbs, from which come out three or four Lily-shaped leaves, of a pale green, with a few faint spots; the stalk rises near a foot high, it is slender, furrowed, and has a very few small leaves which embrace it; this is terminated by a loose spike of white flowers, smelling sweet, which resemble a butterfly with expanded wings. This flowers in June.

The fourth sort is found growing naturally on Cawsham-hills, and in other places where the soil is chalk. The roots of this sort are composed of two bulbs, from which come out four or five oblong leaves; the stalk is about nine inches high, sustaining a loose spike of sweet-smelling flowers, each hanging on a pretty long foot-stalk; they have a short obtuse horn, a crest and wings, of an Ash-colour without, reddish within, and striped with deeper lines; the lip is oblong, divided into five parts, having rough spots. This flowers in June.

The fifth sort grows naturally on chalk-hills in several parts of England; the root of this is composed of two oblong bulbs, from which arise three or four narrow oblong leaves; the stalk rises a foot high, having three or four narrow erect leaves which embrace it. The flowers are produced in a thick roundish spike at the top; they are of a reddish colour, having long spurs, and the wings are acute-pointed. It flowers in June.

The sixth sort grows naturally in moist meadows in many parts of England; the root of this is composed of two fleshy bulbs, which are divided into four or five fingers, so as to resemble an open hand; the stalk rises from nine inches to a foot high, garnished with leaves the whole length, which are three or four inches long and one broad, embracing the stalk with their base; these are not spotted, and end in acute points. The flowers are disposed in a spike on the top of the stalk, with small narrow leaves (called bractea) between them, which are longer than the

flowers. The spur is half an inch long, extended backward; the lip of the nectarium is broad, divided into three lobes, two side ones being reflexed; the flowers and bractea are of a purplish colour, having deep purple spots. It flowers in May. There are two varieties of this, differing in the colour of their flowers, and one with a narrower leaf.

The seventh sort grows naturally in moist meadows in several parts of England; the root of this is composed of two broad fleshy bulbs, both of which are divided into four fingers, which spread asunder. The stalk rises a foot and a half high, and is very strong, inclining to a purple colour; it is garnished with leaves the whole length; those on the lower part of the stalk are six inches long, and an inch and a half broad, embracing it with their base. The flowers are collected in a close spike at the top of the stalk, they are of a pale purple colour; the spur is about a third part of an inch long; the beard of the nectarium is plain, and divided into three parts, which is marked with deep purple spots; under each foot-stalk is placed a narrow leaf (or bractea) of a purplish colour. The leaves and stalks of the plant have many dark spots. It flowers in June. There are two or three varieties of this, which differ in the colour of their flowers.

The eighth sort grows naturally in moist meadows in several parts of England; this hath a double-handed root, that which sustains the stalk being wasting and decaying, but the other is full, succulent, and plump; the finger-like bulbs which compose the root are long, and spread asunder; the lower leaves are six or seven inches long, they are narrow, of a pale green, and have no spots. The stalk rises a foot high, it is garnished with a few narrow short leaves, which embrace it like sheaths; it is terminated by a beautiful spike of red flowers six inches long; the flowers are not marked with any spots; they have long, slender, bristly spurs like birds claws, being crooked; the lip of the nectarium is indented on the edge. It flowers in June.

The ninth sort grows naturally in shady woods in several parts of England, but particularly in Sussex and Hampshire, in both which counties I have several times found it. The root of this plant is composed of many thick, oblique, long fibres, which are fleshy; the stalk rises near two feet high, wrapped round with leaves like sheaths; they are of a purple colour. The flowers are disposed in a loose thyrse at the top of the stalk, and are of a purple colour, having an oval entire lip to the nectarium, the crest terminating in a horn. It flowers in June.

All these sorts of Orchis grow wild in several parts of England, but, for the extreme oddness and beauty of their flowers, deserve a place in every good garden; and the reason for their not being cultivated in gardens, proceeds from their difficulty to be transplanted; though this, I believe, may be easily overcome, where a person has an opportunity of marking their roots in their time of flowering, and letting them remain until their leaves are decayed, when they may be transplanted with safety; for it is the same with most sorts of bulbous or fleshy-rooted plants, which, if transplanted before their leaves decay, seldom live, notwithstanding you preserve a large ball of earth about them; for the extreme parts of their fibres extend to a great depth in the ground, from whence they receive their nourishment; which, if broken or damaged by taking up their roots, seldom thrive after; for though they may sometimes remain alive a year or two, yet they grow weaker until they quite decay; which is also the case with Tulips, Fritillarias, and other bulbous roots, when removed, after they have made shoots; so that whoever would cultivate them, should search them out in their season of flowering, and mark them; and when their leaves are decayed, or just as they are going off, the roots should be taken up, and planted in a soil or situation as nearly resembling that wherein they naturally grow, as possible, otherwise they will not thrive, so that

they cannot be placed all in the same bed; for some are only found upon chalky hills, others in moist meadows, and some in shady woods, or under trees; but if their soil and situation be adapted to their various sorts, they will thrive and continue several years, and, during their season of flowering, will afford as great varieties as any flowers which are at present cultivated.

The other sorts not here enumerated, may be found under the following articles, OPHRYS, SATYRIUM, SERAPIAS.

OREOSELINUM. See ATHAMANTA.

ORIGANUM. Lin. Gen. Plant. 645. Tourn. Inst. R. H. 198. tab. 94. [of ὀρίγανον, of ὄρεος, a mountain, and γάνυμαι, to rejoice, q. d. a plant that delights to grow upon mountains.] Origany or Pot Marjoram; in French, *Origan*.

The CHARACTERS are,

The flower is of the lip kind, having a cylindrical compressed tube; the upper lip is plain, erect, obtuse, and indented; the under lip is trifid, the segments being nearly equal. These are disposed in spikes composed of oval coloured leaves, placed over each other like the scales of fish. The flowers have four slender stamina, two being as long as the petal, the other two are longer, terminated by simple summits; they have a four-cornered germen, supporting a slender style inclining to the upper lip, crowned by a bifid stigma. The germen afterward turns to four seeds shut up in the empalement of the flower.

This genus of plants is ranged in the first section of Linnaeus's fourteenth class, which includes the plants whose flowers have two long and two shorter stamina, and are succeeded by naked seeds. To this genus he has added the Majorana of Tournefort, and the Dictamnus of Boerhaave. The first has its flowers disposed in four-cornered scaly heads, the other has the flowers disposed in loose scaly heads, coming out from between the leaves.

The SPECIES are,

1. ORIGANUM (*Vulgare*) spicis subrotundis paniculatis conglomeratis, bracteis calyce longioribus ovatis. Lin. Sp. Plant. 590. *Pot Marjoram with roundish paniculated spikes gathered in clusters, and oval bractæ which are longer than the empalement. Origanum vulgare spontaneum. I. B. 2. 236. Common Wild Origany.*
2. ORIGANUM (*Heracleoticum*) spicis longis pedunculis aggregatis, bracteis longitudine calycum. Lin. Gen. Plant. 589. *Origany with long spikes growing in bunches, and bractæ as long as the empalement. Origanum heracleoticum, culina Gallinacea Plinii. C. B. P. 223. Winter Sweet Marjoram.*
3. ORIGANUM (*Latifolium*) spicis oblongis paniculatis conglomeratis, foliis ovatis glabris. *Origany with oblong spikes of flowers growing in clustered panicles, and oval smooth leaves. Origanum humilium latifolium glabrum. Tourn. Inst. R. H. 199. Low, broad-leaved, smooth Origany.*
4. ORIGANUM (*Humile*) caule repente, spicis oblongis conglomeratis, bracteis florum longioribus. *Origany with a creeping stalk, and oblong spikes of flowers growing in clusters, with bractæ longer than the flower. Origanum sylvestre, humile. C. B. P. 223. Prod. 109. Low wild Origany.*
5. ORIGANUM (*Orientale*) caule erecto ramoso, foliis ovatis rugosis, spicis subrotundis conglomeratis, bracteis calycum brevioribus. *Origany with an erect branching stalk, oval rough leaves, roundish spikes of flowers growing in clusters, with bractæ shorter than the empalement. Origanum orientale prunellæ folio glauco, flore purpureo. Boerh. Ind. alt. 1. 179. Eastern Origany with a gray Self-heal leaf, and a purple flower.*
6. ORIGANUM (*Creticum*) spicis aggregatis longis prismaticis rectis, bracteis membranaceis, calyce duplo longioribus. Lin. Sp. Plant. 589. *Origany with long, upright, prismatic spikes growing in clusters, and membranous bractæ twice the length of the empalement. Origanum Creticum. C. B. P. 223. Origany of Crete.*
7. ORIGANUM (*Majorana*) foliis ovalibus obtusis, spicis subrotundis compactis pubescentibus. Hort. Cliff. 304.

Origany with oval obtuse leaves, and roundish, compact, hairy spikes. Majorana vulgaris. C. B. P. 224. Common, or Sweet Marjoram.

8. ORIGANUM (*Aegyptiacum*) foliis carnosiss tomentosis, spicis nudis. Lin. Sp. Plant. 822. *Origany with fleshy woolly leaves. Majorana rotundifolia, scutellata, exotica. H. R. Par. Round-leaved foreign Marjoram with a spoon-shaped leaf.*
9. ORIGANUM (*Smyræum*) foliis ovatis acutè serratis, spicis congestis umbellatim fastigiatis. Hort. Cliff. 304. *Origany with oval leaves acutely sawed, and spikes of flowers disposed in umbellated bunches. Origanum Smyræum. Wheel. Raii Hist. 450. Origany of Smyrna.*
10. ORIGANUM (*Dictamnus*) foliis omnibus tomentosis, spicis nutantibus. *Origany with all the leaves woolly, and nodding spikes of flowers. Dictamnus Creticus. C. B. P. 222. The Dittany of Crete.*
11. ORIGANUM (*Sipyleum*) foliis omnibus glabris, spicis nutantibus. Hort. Cliff. 304. *Origany with all the leaves smooth, and nodding spikes of flowers. Dictamnus montis Sipyli origani foliis. Flor. Bat. 2. 72. Dittany of Mount Sipylus with an Origany leaf.*
12. ORIGANUM (*Hybridum*) foliis inferioribus tomentosis, spicis nutantibus. Hort. Cliff. 304. *Origany with the under leaves hoary, and nodding spikes of flowers. Origanum Dictamni Cretici facie, folio crasso, nunc villosa, nunc glabro. Tourn. Cor. 13. Origany with the appearance of Dittany of Crete, and thick leaves sometimes hairy, at others smooth.*
13. ORIGANUM (*Onites*) spicis oblongis aggregatis hirsutis, foliis cordatis tomentosis. Lin. Sp. Plant. 590. *Origany with oblong hairy spikes growing in bunches, and heart-shaped woolly leaves. Origanum lignosum Syracusanum perenne, umbellâ amplissimâ brevi, lato & nervoso folio. Bocc. Mus. 2. p. 43. tab. 38. Ligneous perennial Origany of Syracuse, with a short ample umbel, and a broad-veined leaf.*

The first sort grows naturally in thickets, and among bushes in several parts of England; the root is perennial, composed of many small ligneous fibres. The stalks are square, and rise near two feet high; they are ligneous, and garnished with oval leaves placed by pairs, and from the wings of these come out three or four smaller leaves on each side, which resemble those of Marjoram, sitting close to the stalk; they have an aromatic scent: the flowers are produced in roundish spikes growing in panicles at the top of the stalks, many of the spikes being gathered together; the flowers are of a flesh colour, and peep out of their scaly covering. Their upper lip is cut into two, standing erect, and the lower lip or beard is divided into three parts, and hangs downward the stamina stand out a little beyond the petals, and are of a purplish colour. It flowers in June and July, and the seeds ripen in the autumn. This sort is sometimes cultivated in gardens, and is by some called Pot Marjoram; it is generally used in soups.

It will rise plentifully from scattered seeds, or it may be propagated by parting the roots; the best time for doing this is in autumn, and the roots may be planted in any soil not over moist, and will thrive in any situation, so requires no other care but to keep them clear from weeds. There is a variety of this with white flowers and light green stalks, and another with variegated leaves.

The second sort is now commonly known by the title of Winter Sweet Marjoram, though it was formerly stiled Pot Marjoram. This hath a perennial root, from which arise many branching four-cornered stalks a foot and a half high, which are hairy, and inclining to a purplish colour, garnished with oval, obtuse, hairy leaves, resembling greatly those of Sweet Marjoram, standing by pairs on short foot-stalks; the flowers are disposed in spikes about two inches long, several arising together from the divisions of the stalk. The flowers are small, white, and peep out of their scaly covers; these appear in July, and the seeds ripen in autumn. It grows naturally in Greece and the warm parts of Europe, but is hardy enough to thrive in the

the open air in England, and is chiefly cultivated for nosegays, as it comes sooner to flower than Sweet Marjoram, so it is used for the same purposes, till the other comes to maturity. There is a variety of this with variegated leaves. This is generally propagated by parting the roots in autumn, and should have a dry soil, where it will thrive, requiring no other culture than the first sort.

The third sort grows naturally in France and Italy; this hath a perennial root, from which arise several slender bending stalks near a foot high, garnished with oval smooth leaves standing on pretty long foot-stalks. The flowers are produced in oblong spikes, which grow in clustered panicles; they are small, of a purplish colour, peeping out of their scaly coverings. It flowers in June, and may be propagated by parting the roots in the same way as the former.

The fourth sort grows plentifully about Orleans; this hath a perennial root, from which arise several four-cornered stalks about six inches high, which frequently bend to the ground, and put out roots; they are garnished with oblong hairy leaves sitting close to the stalk. The flowers grow in oblong clustered spikes at the top of the stalks, having long coloured bractæ between each; the flowers are some whitish, others purple in the same spikes; they are small, and peep out of their scaly covers. This flowers in June, and may be propagated in the same way as the former.

The fifth sort grows naturally in the Levant; it is a perennial plant. The stalks rise two feet high, and branch out their whole length; they are purple, and garnished with oval rough leaves, somewhat like those of Self-heal, but smaller. The flowers grow in roundish clustered spikes, having short bractæ; they are purple, and appear in June, but are not succeeded by seeds here. It is propagated by parting of the heads in the same way as the former, and must have a dry soil.

The sixth sort is the Origany of Crete, which is directed to be used in medicine, but there has been great confusion among botanists in distinguishing the species. This rises with four-cornered stalks a foot and half high, garnished with oval hoary leaves of a strong aromatic scent. The flowers grow in long, erect, bunched spikes at the top of the stalks, having membranous bractæ between, which are twice the length of the empalement; the flowers are small and white, like those of the common Origany. It flowers in July, but seldom perfects seeds in England. It is propagated by parting the roots as the former, but must have a dry soil and a warm situation, otherwise it will not live through the winter here.

The seventh sort is the common Sweet Marjoram, which is so well known as to need no description. With us in England it is esteemed an annual plant, though the roots often live through the winter in mild seasons, or if they are sheltered in a green-house; but in warm countries, I believe, it is only biennial.

This is propagated by seeds, which are generally imported from the south of France or Italy, for they seldom ripen in England. These are sown on a warm border toward the end of March, and when the plants are come about an inch high, they should be transplanted into beds of rich earth, at six inches distance every way, observing to water them duly till they have taken new root; after which, they will require no other care but to keep them clean from weeds. The plants will spread and cover the ground; in July they will begin to flower, at which time it is cut for use, and is then called Knotted Marjoram, from the flowers being collected into roundish close heads like knots.

The eighth sort grows naturally in Africa; this is a perennial plant with a low shrubby stalk, seldom rising more than a foot and half high, dividing into branches, which are garnished with roundish, thick, woolly leaves, and hollowed like a ladle; they are like those of the common Marjoram, but are of a thicker substance and woolly, and have much the same scent.

The flowers are produced in roundish spikes, closely joined together at the top of the stalks, and, at the end of the small side branches they are of a pale flesh colour, peeping out of their scaly coverings. This sort flowers in July and August, but does not ripen seeds in England.

It is propagated by slips or cuttings, which if planted in a border of good earth during any of the summer months, and shaded from the sun and duly watered, will take root freely; and afterward the plants may be taken up, and planted in small pots filled with light kitchen-garden earth, and placed in the shade till they have taken new root, when they may be removed into an open situation, where they may remain till the end of October, when they must be placed under shelter, for they will not thrive through the winter in the open air here; but if they are put under a hot-bed frame, where they may be protected from hard frost, and have as much free air as possible in mild weather, they will thrive better than if they are more tenderly treated.

The tenth sort is the Dittany of Crete, which is used in medicine; this grows naturally upon Mount Ida, in Candia; it is a perennial plant. The stalks are hairy, and rise about nine inches high, of a purplish colour, and send out small branches from their sides by pairs; they are garnished with round, thick, woolly leaves, which are very white; the whole plant has a piercing aromatic scent, and biting taste: the flowers are collected in loose leafy heads of a purple colour, which nod downward; they are small, and of a purple colour; the stamina stands out beyond the petal, two of them being much longer than the other. It flowers in June and July, and in warm seasons the seeds sometimes ripen in autumn.

This is propagated easily by planting cuttings or slips during any of the summer months. These should be planted either in pots or a shady border, covering them close with a bell or hand-glass to exclude the air, and now and then refreshing them with water; but they must not have too much wet. When these have taken root, they should be carefully taken up, and each planted into a separate small pot filled with light earth, and placed in the shade till they have taken new root, when they should be removed into an open situation, where they may continue till autumn, and then placed under a hot-bed frame to screen them from the frost, but they should enjoy the free air at all times in mild weather. The following spring some of the plants may be shaken out of the pots, and planted in a warm border near a good aspect wall, and in a dry soil, where the plants will live through the common winters without any other shelter; but as they are liable to be killed by severe frost, it will be proper to keep a few plants in pots, to be sheltered in winter to preserve the kind.

The eleventh sort grows naturally on Mount Sipylus near Magnesia, where it was discovered by Sir George Wheeler, who sent the seeds to the Oxford Garden, where the plants were raised; this hath a perennial root, but an annual stalk. The root is composed of many slender ligneous fibres; the leaves are oval, smooth, and of a grayish colour; the stalks are slender, of a purplish colour, four-cornered, and smooth; they rise near two feet high, sending out slender branches opposite, which are terminated by slender oblong spikes of purplish flowers, which peep out of their scaly covers; the flowers are small, but shaded like those of the tenth sort; their stamina are extended out of the petal to a considerable length. The leaves, on the lower part of the stalk, are almost as large as the common Origany, but those on the upper part of the stalk and branches are very small, and sit close to the stalk. It flowers in June and July, and in warm seasons the seeds ripen here in autumn. It is propagated by cuttings or slips, in the same way as the Cretan Dittany, and the plants require the same treatment.

The twelfth sort is undoubtedly a variety, which has been produced from the intermixing of the farina of

of the Cretan Dittany with that of Mount Sipylus; for the plants now in the Chelsea Garden were accidentally produced from the seeds of one species, where both sorts stood near each other in the garden of John Browning, Esq; of Lincoln's-Inn; the seeds were dropped from the plant into the border between the two sorts, so that it is uncertain from which species; but as the stalks and heads of such flowers bear a greater resemblance to the Dittany of Mount Sipylus, we may suppose it arose from the seeds of that, which had been impregnated by the farina of the Cretan Dittany, which grew near it; for the under leaves of this are round, of a thick texture and woolly, so nearly resembling those of the Cretan Dittany, as not to be distinguished from it; but the stalks rise full as high as those of the Dittany of Sipylus, but branch out more their whole length; they are of a purple colour and hairy. The lower leaves on the stalks are much larger than those of Mount Sipylus, and are hairy, approaching to those of the Cretan Dittany, but are not so thick or woolly; the upper leaves are smooth, and approach to those of the other sort, but are larger, as are also the spikes of flowers, and the scaly leaves which cover the flowers are larger and of a deeper purple colour.

I have also dried samples of another variety, which arose from seeds in the Leyden Garden; the seeds were sent from Paris, by the title which Tournefort gave to that which he found in the Levant, which I have joined to the variety before-mentioned. The leaves of this are as large as those of the Dittany of Crete, but are not so thick or woolly; the stalks rise more like those of the Dittany of Mount Sipylus, but branch out wider at the top; the flowers grow in closer clusters, and do not nod downward; they are small, and shaped like those of the former sort, flowering at the same time.

By the title which Dr. Linnæus has given to the Cretan Dittany, it may be supposed he has not seen the true sort, for his title better suits the variety to which I have applied it; for all the leaves of the true Dittany are very thick and woolly, even those which are situated immediately below the flowers, whereas the lower leaves only are so in this title.

The thirteenth sort grows at Syracuse; this hath perennial ligneous stalks which rise a foot and a half high, dividing into many small branches, which are garnished with small heart-shaped leaves a little larger than those of Marjoram, which are woolly. The flowers grow in oblong tufted spikes which are hairy; they are small, white, and peep out of their scaly covers; they appear in July, but seldom perfect seeds in England. This is propagated by cuttings or slips, in the same way as the tenth sort, and the plants require the same treatment.

The first and sixth sorts are used in medicine, but the first being a native of this country, is frequently substituted for the other, which is pretty rare in England, and is now seldom imported here. When the first sort is used, those plants which grow upon dry barren ground are to be preferred, as they are much stronger and have greater virtue than those which grow on good land, or are cultivated in gardens.

The Dittany of Crete is also used in medicine; but the dried herb is generally imported into England, which, by being closely packed, and the voyage being long, it loses much of its virtue; so that if the plants of English growth were used, they would be found much better.

ORNITHOGALUM. Tourn. Inst. R. H. 378. tab. 203. Lin. Gen. Plant. 377. [*ὄρνιθόγαλον*, of *ὄρνις*, a bird, and *γάλα*, milk, i. e. a plant whose flowers are as white as the white plumes of feathered animals.] Star of Bethlehem.

The CHARACTERS are,

The flower has no enpalement. It is composed of six petals, whose under parts are erect, but spread open above, and are permanent. It hath six erect stamina about half the length of the petals, crowned by single summits; with an angular germen, supporting an awl-shaped style which is

permanent; terminated by an obtuse stigma. The germen afterward turns to a roundish angular capsule with three cells, filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, in which are contained those plants whose flowers have six stamina and one style.

The SPECIES are,

1. **ORNITHOGALUM** (*Pyrenaicum*) racemo longissimo, filamentis lanceolatis, pedunculis floriferis patentibus aequalibus, fructiferis scapo approximatis. Lin. Sp. Plant. 440. *Star-flower with a very long spike of flowers, spear-shaped filaments, and foot-stalks to the flowers equal, spreading, and those of the fruit approaching to the stalk.* Ornithogalum angustifolium majus, floribus ex albo virescentibus. C. B. P. 70. *Greater narrow-leaved Star-flower, with whitish green flowers.*
2. **ORNITHOGALUM** (*Pyramidale*) racemo conico, floribus numerosis adscendentibus. Prod. Leyd. 32. *Star-flower with a conical spike, having numerous flowers rising above each other.* Ornithogalum angustifolium, spicatum, maximum. C. B. P. 70. *Largest spiked Star-flower with a narrow leaf.*
3. **ORNITHOGALUM** (*Latifolium*) racemo longissimo, foliis lanceolato-ensiformibus. Lin. Sp. Plant. 307. *Star-flower with the longest spike, and spear-shaped leaves.* Ornithogalum latifolium & maximum. C. B. P. 70. *Greatest broad-leaved Star-flower, called the Star-flower of Alexandria.*
4. **ORNITHOGALUM** (*Nutans*) floribus secundis pendulis, nectario stamineo campaniformi. Lin. Sp. Plant. 308. *Star-flower with fruitful hanging flowers, and a bell-shaped nectarium.* Ornithogalum Neapolitanum. Clus. App. 2. p. 9. *Star-flower of Naples.*
5. **ORNITHOGALUM** (*Luteum*) scapo angulato diphylo, pedunculis umbellatis simplicibus. Flor. Suec. 270. *Star-flower with an angular stalk having two leaves, and single umbellated foot-stalks.* Ornithogalum luteum. C. B. P. 71. *Yellow Star-flower.*
6. **ORNITHOGALUM** (*Minimum*) scapo angulato diphylo, pedunculis umbellatis ramosis. Flor. Suec. 271. *Star-flower with an angular stalk bearing two leaves, and branching foot-stalks having umbels.* Ornithogalum luteum minus. C. B. P. 71. *Smaller yellow Star-flower.*
7. **ORNITHOGALUM** (*Umbellatum*) floribus corymbosis, pedunculis scapo altioribus, filamentis emarginatis. Hort. Cliff. 124. *Star-flower with flowers growing in a corymbus, whose foot-stalks are taller than the stalk, and indented filaments.* Ornithogalum umbellatum medium angustifolium. C. B. P. 70. *Middle umbellated Star-flower having narrow leaves.*
8. **ORNITHOGALUM** (*Arabicum*) floribus corymbosis, pedunculis scapo humilioribus, filamentis emarginatis. Prod. Leyd. 32. *Star-flower with flowers growing in a corymbus, foot-stalks lower than the stalk, and indented filaments.* Ornithogalum Arabicum. Clus. Hist. 11. p. 186. *Star-flower of Arabia.*
9. **ORNITHOGALUM** (*Capense*) foliis cordatis ovatis. Prod. Leyd. 31. *Star-flower with oval heart-shaped leaves.* Ornithogalum Africanum plantaginis roseæ folio, radice tuberosâ. Hort. Amst. 2. p. 175. *African Star-flower, with a Rose Plantain leaf and a tuberous root.*
10. **ORNITHOGALUM** (*Tuberosum*) racemo brevissimo, foliis teretibus fistulosis. *Star-flower with a very short spike, and taper fistular leaves.* Ornithogalum Africanum, luteum odoratum, foliis cepaceis, radice tuberosâ. H. L. *African Star-flower having yellow sweet flowers, leaves resembling those of the Onion, and a tuberous root.*

The first sort grows naturally near Bristol, and also near Chichester in Suffex, and some other parts of England. This hath a pretty large bulbous root, from which come out several long keel-shaped leaves, which spread on the ground; between these come out a single naked stalk about two feet long, sustaining a long loose spike of flowers of a yellowish green colour, standing upon pretty long foot-stalks, which spread wide from the principal stalk; the petals of the flowers are narrow, making but little appearance. The flowers have an agreeable scent; they appear in May, and when the seed-vessels are formed, the foot-

stalks

stalks which sustain them become erect, and approach near the stalk: The seeds ripen in August.

The second sort grows naturally upon the hills in Portugal and Spain, but has been long cultivated in the English gardens by the title of the Star of Bethlehem. This hath a very large, oval, bulbous root, from which arise several long keel-shaped leaves of a dark green colour, in the middle of which come out a naked stalk which rises near three feet high, terminated by a long conical spike of white flowers, standing upon pretty long foot-stalks, rising one above another in an upright spike. These appear in June, and are succeeded by roundish seed-vessels, having three cells filled with roundish seeds, which ripen in August.

The third sort grows naturally in Arabia; this hath a very large bulbous root, from which come out several broad sword-shaped leaves, which spread on the ground; the stalk is thick and strong, rising between two and three feet high, bearing a long spike of large white flowers, standing upon long foot-stalks. They are composed of six petals which spread open in form of a star, and appear in June, but do not ripen their seeds in England.

The fourth sort grows in great abundance naturally in the kingdom of Naples, and is now become almost as common in England, for the roots propagate so fast by offsets and seeds, as to become troublesome weeds in gardens; and in many places where the roots have been thrown out of gardens, they have grown upon dunghills and in waste places as plentifully as weeds. This hath a pretty large, compressed, bulbous root, from which come out many long, narrow, keel-shaped leaves, of a dark green colour. The stalks are very thick and succulent, rising about a foot high, sustaining ten or twelve flowers in a loose spike, each hanging on a foot-stalk an inch long; they are composed of six petals, which are white within, but of a grayish green on their outside, having no scent; within the petals is situated the bell-shaped nectarium, composed of six leaves, out of which arise the six stamina, terminated by yellow summits. The flowers appear in April, and are succeeded by large, roundish, three-cornered capsules, which are filled with roundish seeds; as the capsules grow large, they are so heavy as to weigh the stalk to the ground.

The sixth sort hath small bulbous roots not larger than Peas, from which arise one or two narrow keel-shaped leaves about five inches long, of a grayish colour; the stalk is angular, and rises about four inches high, having two narrow keel-shaped leaves just below the flowers, which are disposed in an umbel upon branching foot-stalks; these are yellow within, but of a purplish green on their outside. They appear in May, and are succeeded by small triangular capsules, filled with reddish uneven seeds. It grows on the borders of cultivated fields in France and Germany.

The seventh sort grows naturally in most parts of Europe, and is supposed to do so in England, though it is seldom found here, unless in orchards or grounds where the roots may have been planted, or thrown out of gardens with rubbish. This hath a bulb as large as a small Onion, to which adhere many small offsets: the leaves are long, narrow, and keel-shaped, spreading on the ground, and have a longitudinal white line through the hollow. The stalk rises about six inches high, sustaining an umbel of flowers which are white within, but have broad green stripes on the outside of the petals; these stand upon long foot-stalks, which rise above the principal stalk. It flowers in April and May, and is succeeded by roundish three-cornered capsules filled with angular seeds, which ripen in July.

The eighth sort grows naturally in Arabia; this hath a large bulbous root, from which arise many long keel-shaped leaves, which embrace each other with their base; they are of a deep green, and stand erect. The flowers of this kind I have never yet seen, though I have tried many ways to procure them: the roots multiply exceedingly, and are never injured by frost,

although the leaves are put out before winter. These roots are frequently brought over from Italy for sale, but I have not heard of any having flowered; and Clusius says, he never saw but one root flower, and that came from Constantinople.

The ninth sort grows naturally at the Cape of Good Hope; this hath an irregular tuberous root, varying greatly in form and size, covered with a dark brown skin, from which arise several oval heart-shaped leaves, upon pretty long foot-stalks; they have several longitudinal veins like Ribwort Plantain. The flower-stalks are slender, naked, and rise about a foot high, sustaining several small, greenish, white flowers, formed in a loose spike, standing upon long slender foot-stalks. They come out in November, making but little appearance, and are not succeeded by seeds in England.

The tenth sort grows naturally on the dry rocks at the Cape of Good Hope; this hath a large, depressed, bulbous root, as big as a man's fist, covered with an uneven brown skin, putting out several taper hollow leaves nine or ten inches long, between which comes forth a naked stalk near a foot high, terminated by a loose spike of yellow flowers, of an agreeable sweet scent. It flowers in May, but does produce seeds in England.

The three sorts first mentioned, are cultivated for ornament in the English gardens. These are propagated by offsets, which their roots commonly produce in great plenty. The best time to transplant their roots is in July or August, when their leaves are decayed; for if they are removed late in autumn, their fibres will be shot out, when they will be very apt to suffer if disturbed. They should have a light sandy soil, but it must not be over dunged. They may be intermixed with other bulbous-rooted flowers in the borders of the pleasure-garden, where they will afford an agreeable variety. Their roots need not be transplanted oftener than every other year, for if they are taken up every year, they will not increase so fast; but when they are suffered to remain too long unremoved, they will have so many offsets about them as to weaken their blowing roots. These may also be propagated from seeds, which should be sown and managed as most other bulbous-rooted flowers, and will produce their flowers three or four years after sowing.

The fourth sort is scarce worthy of a place in gardens, but as it will thrive in any situation or under trees, so a few plants may be admitted in obscure places for the sake of variety.

The fifth sort has not much beauty, therefore a few roots of it will be enough for variety, as also of the sixth and seventh sorts; the two last will thrive in shade, but the fifth should have an open situation.

The eighth sort multiplies so fast by offsets from the roots as to become troublesome weeds in a garden, for every small root will grow, and in two years produce twenty or thirty more; so that unless the large roots are taken up every year and divested of their offsets, the borders will be over-run with them.

The ninth sort is too tender to thrive in the open air in England, so the roots of this should be planted in pots filled with light earth, and in the autumn placed under a hot-bed frame, where they may be screened from frost, and in mild weather enjoy the free air. The leaves of this appear in the autumn, and continue growing all the winter, so must not be exposed to frost; nor should they be drawn up weak, for then the flowers will be few on a stalk, and not large. If the pots do now and then receive a gentle shower of rain in winter it will be sufficient, for they should not have much wet during that season. Toward the beginning of July the leaves and stalks decay, and then the roots may be taken up, laying them in a dry cool place till the end of August, when they must be planted again.

The other species which were included in this genus, are now removed to Scilla.

ORNITHOPUS. Lin. Gen. Plant. 790. Ornithopodium. Tourn. Inst. R. H. 400. tab. 224. Bird's-foot; in French, *Pic-d'oiseau*.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, tubulous, and indented in five equal segments at the brim. The flower is of the butterfly kind, the standard is heart-shaped and entire; the wings are oval, erect, and almost as large as the standard; the keel is small and compressed. It hath ten stamina, nine of which are joined, and one stands separate, terminated by single summits. The germen is narrow, supporting a bristly ascending style, terminated by a punctured stigma. The germen afterward becomes a taper incurved pod, having many joints connected together, but when ripe separate, each containing one oblong seed.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes the plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. **ORNITHOPUS** (*Perpusillus*) foliis pinnatis, leguminibus compressis subarcuatis. Hort. Upsal. 234. *Bird's-foot with winged leaves, and compressed pods a little arched.* Ornithopodium majus. C. B. P. 350. *Greater Bird's-foot.*
2. **ORNITHOPUS** (*Nodosa*) foliis pinnatis, leguminibus confertis pedunculatis. *Bird's-foot with winged leaves, and pods growing in clusters upon foot-stalks.* Ornithopodium radice tuberculis nodosa. C. B. P. 350. *Bird's-foot with knobbed tubercular roots.*
3. **ORNITHOPUS** (*Compressus*) foliis pinnatis, pinnis leguminibus compressis rugosis. Hort. Cliff. 364. *Bird's-foot with linear winged leaves, and compressed pods growing in pairs.* Ornithopodium Scorpoides, siliqua compressa. Tourn. Inst. 400. *Bird's-foot with the appearance of Caterpillar, and flat pods.*
4. **ORNITHOPUS** (*Scorpioides*) foliis ternatis subsessilibus impari maximo. Hort. Cliff. 364. *Bird's-foot with trifoliate leaves sitting close to the stalk, and the middle lobe very large.* Ornithopodium Portulacæ folio. Tourn. Inst. 400. *Bird's-foot with a Purslane leaf.*

The first sort grows naturally in the south of France, in Spain and Italy. It is an annual plant, having many trailing stalks a foot and a half long, from which come out a few side branches, garnished with long winged leaves, composed of about eighteen pair of small oval lobes, terminated by an odd one; these lobes stand sometimes opposite, and at others they are alternate and hairy. The flowers are produced in small clusters at the top of foot-stalks, which arise from the wings of the stalks, and are near three inches long, having a small winged leaf, part of which is below, and the other part above the flowers, so that they seem to come from the midrib of the leaf; the flowers are of a deep gold colour, and shaped like a butterfly. These appear in July, and are succeeded by flat narrow pods about three inches long, which turn inward at the top like a bird's claw. They are jointed, and a little hairy, containing a single seed in each joint, which ripens in autumn, when the joints separate and fall asunder.

The second sort grows naturally on dry commons and heaths in most parts of England. The root of this sort is composed of two or three strong fibres, to which hang several small tubercles or knobs like grains. There are many slender stalks come out from the root, and spread on the ground, from four to eight inches long, garnished with small, winged, hairy leaves, composed of six or seven pair of narrow lobes, terminated by an odd one. The flowers stand upon long slender foot-stalks, which come out at every joint of the stalk; they are small, of a yellow colour, and are succeeded by clusters of short pods, which are a little incurved at the top. It flowers and seeds about the same time as the former. The third sort grows plentifully about Messina and Naples. The root of this sort runs deep into the ground, sending out a few small fibres on the side; the stalks are about six inches long, and do not lie flat on the ground like the other; the leaves are hairy, composed of ten or twelve pair of narrow lobes placed

along the midrib, terminated by an odd one. The flowers grow in small bunches on the top of the branches; they are yellow, and are generally succeeded by two flat pods not much more than an inch long, turned inward like a bird's claw. This flowers and seeds about the same time with the former.

The fourth sort grows naturally among the Corn in Spain and Italy; this hath many smooth branching stalks, which rise near two feet high, garnished toward their top with trifoliate oval leaves sitting close, having two small appendages. The lower leaves are often single, and of a grayish colour, the middle lobe being twice the size of the two side ones. The flowers stand upon slender foot-stalks, are yellow, and succeeded by taper pods, which are two inches long, shaped like a bird's claw. This flowers and seeds about the same time with the former.

These plants are propagated by sowing their seeds in the spring upon a bed of light fresh earth, where they are to remain (for they seldom do well when they are transplanted;) when the plants come up, they must be carefully cleared from weeds; and where they are too close, some of the plants should be pulled out, so as to leave the remaining ones about ten inches asunder. In June these plants will flower, and the seeds will ripen in August. There is no great beauty in them, but for the variety of their jointed pods, they are preserved by some curious persons in their pleasure-gardens; where, if their seeds are sown in patches in the borders, each sort distinctly by itself, and the plants thinned, leaving only two at each patch, they will require no farther care, and will add to the variety, especially where the Snail and Caterpillar plants are preserved, which are very proper to intermix with them. They are all annual plants, which perish soon after the seeds are ripe.

OROBANCHE, or Broom Rape.

There are six or seven species of this genus at present known, two of which grow naturally on dry grounds in several parts of England; but as all the sorts do not agree with culture, so they are not admitted into gardens. They are ranged in the second section of Linnæus's fourteenth class, intitled Didynamia Angiospermia, the flowers having two long and two shorter stamina, and their seeds being included in a capsule.

OROBUS. Tourn. Inst. R. H. 393. tab. 214. Lin. Gen. Plant. 780. [*ὀρός*, of *ἐπίρω*, to eat, *βῆς*, an ox, q. d. an herb with which oxen are fed, because the ancients used to fatten their oxen with a like herb.] Bitter Vetch; in French, *Orobe*.

The CHARACTERS are,

The empalement of the flower is tubulous, of one leaf, with an obtuse base; the brim is oblique and indented in five parts, the three lower acute, the two upper shorter and obtuse. The flower is of the butterfly kind; the standard is heart-shaped; the two wings are almost as long as the standard, and join together; the keel is bifid, acute-pointed, and rising upwards; the borders are compressed, and the body swollen. It hath ten stamina, nine are joined, and one separate; these are rising, and terminated by roundish summits. It hath a cylindrical compressed germen, supporting a crooked rising style, crowned by a narrow downy stigma, fastened by the inner edge in the middle to the point of the style. The germen afterward becomes a long taper pod ending in an acute point, having one cell, containing several roundish seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which contains those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. **OROBUS** (*Vernus*) foliis pinnatis ovatis, stipulis semisagittatis integerrimis, caule simplici. Lin. Sp. Plant. 728. *Bitter Vetch with oval winged leaves, entire stipulæ half arrow-pointed, and a single stalk.* Orobus sylvaticus purpureus vernus. C. B. P. 351. *Purple, vernal, wood Bitter Vetch.*
2. **OROBUS** (*Tuberosus*) foliis pinnatis lanceolatis, stipulis semisagittatis, caule simplici. Lin. Sp. Plant. 728. *Bitter*

- Bitter Vetch with spear-shaped winged leaves, entire half arrow-pointed stipule, and a single stalk.* *Orob. Sylvaticus foliis oblongis glabris.* Tourn. Inst. R. H. 393. *Wood Bitter Vetch with oblong smooth leaves.*
3. *OROBUS (Sylvaticus) caulibus decumbentibus hirsutis ramosis.* Cent. pl. 67. Flor. Angl. 275. *Bitter Vetch with hairy, branching, decumbent stalks.* *Orob. Sylvaticus nostras.* Raii Syn. 324. *Wood Bitter Vetch.*
4. *OROBUS (Niger) caule ramoso, foliis sexjugis ovato-oblongis.* Hort. Cliff. 366. *Bitter Vetch with a branching stalk, and leaves composed of six pair of oblong oval lobes.* *Orob. Sylvaticus foliis viciæ.* C. B. P. 352. *Wood Bitter Vetch with a Vetch leaf.*
5. *OROBUS (Pyrenaicus) caule ramoso, foliis bijugis lanceolatis nervosis, stipulis subspinosis.* Lin. Sp. 1029. *Bitter Vetch with a branching stalk, and leaves composed of two pair of nervous spear-shaped lobes.* *Orob. Pyrenaicus, foliis nervosis.* Tourn. Inst. 393. *Bitter Vetch of the Pyrenees with nervous leaves.*
6. *OROBUS (Lathyroides) foliis conjugatis subfessilibus, stipulis dentatis.* Hort. Upsal. 220. *Bitter Vetch with leaves placed by couples close to the stalks, and indented stipule.* *Lathyroides erecta, folio ovato acuminato, cæruleis viciæ floribus & siliquis, Sibirica.* Amman. Ruth. 151. *Siberian, upright, Bastard Lathyrus, with an oval acute-pointed leaf, blue flowers, and pods like those of the Vetch.*
7. *OROBUS (Luteus) foliis pinnatis ovato-oblongis, stipulis rotundato-lunatis dentatis, caule simplici.* Lin. Sp. Plant. 728. *Bitter Vetch with oval, oblong, winged leaves, roundish, moon-shaped, indented stipule, and a single stalk.* *Orob. Sibiricus perenne.* Gmel. *Perennial Siberian Bitter Vetch.*
8. *OROBUS (Veneticus) foliis pinnatis ovatis acutis, quatuor-jugatis, caule simplici.* Tab. 193. fol. 2. *Bitter Vetch with oval, acute-pointed, winged leaves, having four pair of lobes and a single stalk.* *Orob. Veneticus.* Clus. Hist. 232. *Venetian Bitter Vetch.*
9. *OROBUS (Americus) foliis pinnatis linearilanceolatis inferne tomentosis, caule ramosissimo frutescente.* *Bitter Vetch with linear, spear-shaped, winged leaves, which are woolly on their under side, and a very branching shrubby stalk.* *Orob. Americanus erectus, foliorum pinnis angustioribus & subtus incanis, siliquis glabris.* Houst. MSS. *Upright American Bitter Vetch, with very narrow lobes to the leaves, hoary on their under side, and having smooth pods.*
10. *OROBUS (Argenteus) foliis pinnatis oblongo-ovatis inferne sericeis, caule erecto tomentoso, floribus spicatis terminalibus.* *Bitter Vetch with oblong, oval, winged leaves, which are silky on their under side, and have an upright woolly stalk, terminated by a spike of flowers.* *Orob. Americanus, latifolius, argenteus, flore purpureo.* Houst. MSS. *Broad-leaved, silvery, American Bitter Vetch, with a purple flower.*
11. *OROBUS (Procumbens) foliis pinnatis, foliolis exterioribus majoribus tomentosis, caule procumbente.* *Bitter Vetch with winged leaves, whose outer lobes are woolly, and a trailing stalk.* *Orob. Americanus procumbens & hirsutus, flore purpureo.* Houst. MSS. *Trailing, hairy, American Bitter Vetch, with a purple flower.*
12. *OROBUS (Coccineus) foliis pinnatis, foliis linearibus villosis, caule procumbente floribus alaribus & terminalibus.* *Bitter Vetch with winged leaves, having hairy linear lobes, a trailing stalk, and flowers growing on the sides and at the ends of the branches.* *Orob. Americanus procumbens minimus, flore coccineo.* Houst. MSS. *The least trailing American Bitter Vetch, having a scarlet flower.*

The first sort grows naturally in the forests of Germany and Switzerland. The root of this is perennial, composed of many strong fibres; the stalks rise a foot high, and are garnished with winged leaves, composed of two pair of oval acute-pointed lobes, and at the base of the foot-stalk is situated a stipula, (or small leaf,) shaped like the point of an arrow cut through the middle. This embraces the stalk. The lobes of the leaves are about an inch and an half long, and near an inch broad, ending in acute points.

The flowers stand upon foot-stalks, which arise from the wings of the stalk; they are about three inches long, sustaining six or seven flowers ranged in a spike, which are of the butterfly kind. These are at first of a purple colour, but afterward change blue; they appear early in the spring, and are succeeded by slender taper pods an inch and a half long, having one cell, in which are lodged four or five oblong bitter seeds, which ripen in June. There is a variety of this with pale flowers, which is preserved in some gardens. The second sort grows naturally in woods and shady places in most parts of England. This hath a perennial creeping root, from which arise angular stalks nine or ten inches long, garnished at each joint by one winged leaf, composed of four pair of smooth spear-shaped lobes, and, at the base of each, is situated a stipula like that of the first sort; and from the wings of the stalks arise the foot-stalks of the flowers, which are about four inches long, each sustaining two or three purplish red flowers, which turn to a deep purple before they fade. They appear in April, and are succeeded by long taper pods, containing six or seven roundish seeds, which ripen the beginning of June. These are called Wood or Heath Peas.

The third sort grows naturally in Cumberland and Wales. The root is perennial and ligneous, from which arise several hairy stalks a foot and a half high, garnished at each joint with one winged leaf, composed of ten or eleven pair of narrow lobes ranged close together along the midrib; at the base of which is situated an acute stipula embracing the stalk. The flowers are disposed in a close spike, standing upon foot-stalks three inches long, which arise from the wings of the leaves; they are of a purple colour, and are succeeded by short flat pods, containing two or three seeds. It flowers the beginning of June, and the seeds ripen in July.

The fourth sort grows naturally on the mountains in Germany and Switzerland. This hath a strong, ligneous, perennial root, from which arise many branching stalks two feet high, garnished at each joint by one winged leaf, composed of five or six small, oblong, oval lobes ranged along the midrib. The flowers stand upon very long foot-stalks, which arise from the wings of the stalk; these sustain at their top four, five, or six purple flowers, which appear in May, and are succeeded by compressed pods an inch and a half long, containing four or five oblong seeds, which ripen the beginning of July. The stalks decay in autumn, and new ones arise in the spring.

The fifth sort grows naturally on the Pyrenean mountains; this hath a perennial root, from which arise several smooth branching stalks a foot and a half high, garnished with winged leaves composed of four pair of spear-shaped lobes, which have three longitudinal veins; at the base of the leaves is situated a stipula embracing the stalk, in the same manner as the first. The flowers stand upon long foot-stalks, arising from the wings of the leaves; toward the upper part of the stalk they are ranged in a loose spike, are of a purple colour, appearing in May, and are succeeded by compressed pods about two inches long, containing three or four seeds, which ripen in July.

The sixth sort grows naturally in Siberia; this hath a perennial root, from which arise three or four branching stalks about a foot high. The leaves stand by pairs opposite along the stalks, to which they sit close, having an indented stipula at their base; the leaves are smooth, stiff, and of a lucid green. The flowers grow in close spikes upon short foot-stalks, which rise from the wings of the leaves at the top of the stalks, where are generally three or four of these spikes standing together. The flowers are of a fine blue colour, so make a pretty appearance. These appear in June, and are succeeded by short flattish pods, containing two or three seeds in each, which ripen in August.

The

The seventh sort grows naturally in Siberia; this hath a perennial root, from which arise several herbaceous stalks a foot and a half high, garnished with winged leaves, composed of four or five pair of oval oblong lobes, having at their base a roundish moon-shaped stipula embracing the stalk. The flowers come out from the wings of the leaves upon short foot-stalks; they are large and of a purple colour, appearing in April, and are succeeded by swelling pods near two inches long, containing four or five seeds, which ripen in June.

The eighth sort grows naturally in Italy; this hath a perennial root, from which arise several stalks about a foot high, garnished with winged leaves, composed of four pair of oval lobes, ending in acute points; they are smooth and of a pale green colour, placed pretty far distant on the midrib. The flowers come out upon slender foot-stalks, which arise from the wings of the leaves, four or five standing at the top; they are of a purple colour, and appear in March. These are succeeded by swelling pods an inch and a half long, each containing three or four roundish seeds, which ripen in May.

The ninth sort grows naturally in Jamaica, from whence the late Dr. Houstoun sent the seeds in 1731. This rises with a very branching stalk about three feet high, which is ligneous; the branches are garnished with winged leaves, composed of five or six pair of narrow spear-shaped lobes, which are woolly on their under side. The flowers grow in loose spikes at the end of the branches, are of a pale purple colour, and are succeeded by smooth compressed pods an inch and a half long, each containing five or six roundish seeds.

The tenth sort was discovered by the late Dr. Houstoun at La Vera Cruz, from whence he sent the seeds to England. This rises with a shrubby stalk five or six feet high, dividing into many slender branches, which are covered with a brown woolly bark, and garnished with soft, fatty, winged leaves; those on the young branches are composed of four pair of oval obtuse lobes, of a brownish green colour, hairy on their upper side, but of a silvery silky hue on their under. The leaves on the upper branches are composed of seven or eight pair of oblong oval lobes, of the same colour and consistence as the lower. The flowers are produced in long erect spikes at the end of the branches; they are of a deep purple colour, and are succeeded by long, woolly, compressed pods, each containing four or five seeds.

The eleventh sort was discovered by Dr. Houstoun at La Vera Cruz, who sent it to England in 1730. This is a low plant, whose stalks bend to the ground, and are seldom more than six or eight inches long, from which come out a few short side branches; they are garnished with winged leaves, composed of four or five pair of small, oblong, oval, woolly lobes, terminated by an odd one, the upper lobes being much larger than the lower. The flowers come out in small bunches, standing upon short foot-stalks, which arise from the wings of the stalk; they are small, and of a bright purple colour; these are succeeded by compressed pods near two inches long, each having six or seven roundish compressed seeds.

The twelfth sort was discovered at the same time, growing naturally in the same country as the former, by the same gentleman. This hath a pretty thick ligneous root, which sends out many slender stalks a foot and a half long, trailing upon the ground, garnished with winged leaves, composed of three or four pair of narrow hoary lobes, about half an inch long. The flowers come out from the side and at the end of the stalks, three or four standing upon a short foot-stalk; they are small and of a scarlet colour, and are succeeded by short taper pods, each containing three or four small roundish seeds.

The eight sorts which are first mentioned, have perennial roots but annual stalks, which decay every autumn; several of these may be propagated by parting their roots; the best time for doing this is in the

autumn, that the plants may be well established before the spring; for as several of them begin to put out their stalks very early in the spring, so if they are then disturbed, it will either prevent their flowering, or cause their flowers to be very weak. Most of these plants delight in a shady situation, and love a loamy soil.

They are also propagated by seeds, but these should be sown in the autumn, for if they are kept out of the ground till spring, many of the sorts will never grow, and those which do, seldom vegetate the same year; and the fourth sort I could never raise from seeds sown in the spring, though I have made the trial in different situations many times; but the seeds which have scattered in the summer, have come up well the following spring, as have also those which were sown in September. When the plants come up they must be kept clean from weeds, and where they are too close together they should be thinned; so as they may have room to grow till the autumn, when they should be transplanted into the places where they are designed to remain. If the roots are strong, they will flower very well the following spring, but those which are weak will not flower till the second year; therefore such may be planted in a shady border at four or five inches distance, where they may grow one year to get strength, and then may be removed to the places where they are to remain. The farther care of them is only to dig the ground between them in winter, and in summer to keep them clean from weeds.

The four last mentioned sorts being natives of warm countries are tender, so must be preserved in stoves, otherwise they will not live in England. These are propagated by seeds, which should be sown early in the spring, in small pots filled with light rich earth, and plunged into a hot-bed of tanners bark, observing frequently to moisten the earth, otherwise the seeds will not grow. When the plants come up, they should be carefully taken out of the pots, and each transplanted into separate small pots filled with rich earth, and then plunged again into the tan-bed, observing to shade them until they have taken root; after which time they should have fresh air admitted to them every day in warm weather, and must be frequently watered. With this management the plants will make a great progress. When any of the plants are grown too tall to remain in the hot-bed, they should be taken out, and plunged into the bark-bed in the stove, where they may have room to grow, especially the ninth and tenth sorts; but the other two being of humbler growth, may be kept in the hot-bed until Michaelmas, when the nights begin to be cold; at which time they should be removed into the stove, and plunged into the bark-bed, where they must be treated as other tender exotic plants; by which method they may be preserved through the winter, and the following summer they will produce flowers. These plants are perennial, so that if they should not perfect their seeds, the plants may be maintained for several years.

ORTEGIA HISPANICA.

This is called by Clusius, *Juncaria Salmantica*; it is a low trailing plant, with Rush-like stalks, producing at the joints a few small almost invisible flowers, therefore the plant is seldom cultivated except in botanic gardens for variety.

ORYZA. Tourn. Inst. R. H. 513. tab. 296. Rice; in French, *Ris*.

The CHARACTERS are,

The chaff is small, acute-pointed, having two valves nearly equal, inclosing a single flower. The petal has two valves, which are hollow, compressed, and boat-shaped, ending in a beard or awn. It has a two-leaved nectarium, and six hairy stamina the length of the petal, terminated by summits whose base are bifid; and a turbinated germen, supporting two reflexed hairy styles, crowned by feathered stigmas. The germen afterward becomes one large, oblong, compressed seed, having two channels on each side, sitting on the petal of the flower.

This

This genus of plants is ranged in the second section of Linnæus's sixth class, which contains those plants whose flowers have six stamina and two styles.

We have but one SPECIES of this plant, viz.

ORYZA (*Sativa*.) Matth. 403. Rice.

This grain is greatly cultivated in most of the eastern countries, where it is the chief support of the inhabitants; and great quantities of it are brought into England and other European countries every year, where it is in great esteem for puddings, &c. it being too tender to be produced in these northern countries, without the assistance of artificial heat; but from some seeds which were formerly sent to South Carolina, there have been great quantities produced; and it is found to succeed as well there as in its native country, which is a very great improvement to our American settlements.

This plant grows upon moist soils, where the ground can be flowed over with water after it is come up; so that whoever would cultivate it in England for curiosity, should sow the seeds upon a hot-bed; and when the plants are come up, they should be transplanted into pots filled with rich light earth, and placed into pans of water, which should be plunged into a hot-bed; and as the water wastes, so it must, from time to time, be renewed again, still preserving the water in the pans, otherwise they will not thrive, and keeping them in a stove all the summer; and toward the latter end of August, they will produce their grain, which will ripen tolerably well, provided the autumn proves favourable.

OSIER. See SALIX.

OSMUNDA, the Osmund Royal, or flowering Fern.

This is one of the kinds of Fern which is distinguished from the other sorts, by its producing flowers on the top of the leaves; whereas the others, for the most part, produce them on the back of their leaves.

There is but one kind of this plant, which grows wild in England, but there are several sorts of them which grow in America; but as they are seldom kept in gardens, I shall not enumerate their species.

The common sort grows on bogs in several parts of England, therefore whoever hath an inclination to transplant it into gardens, should place it in a moist shady situation, otherwise it will not thrive.

OSTEOSPERMUM. Lin. Gen. Plant. 887. Monilifera. Vaill. Act. Par. 1720. Chrysanthemoides. Tourn. Act. Par. 1705. Hard-seeded Chrysanthemum.

The CHARACTERs are,

The flower hath an hemispherical empalement, which is single, and cut into many segments. The flower is composed of several hermaphrodite florets in the disk, which are tubulous, and cut at the brim into five parts. These are surrounded by several female florets, which are radiated, each having a long narrow tongue, which is cut into three parts at the top. The hermaphrodite florets have each five slender short stamina, terminated by cylindrical summits, with a small germen supporting a slender style, crowned by an obsolete stigma; these are barren. The female florets have each a globular germen supporting a slender style, crowned by an indented stigma; the germen afterward becomes one single hard seed.

This genus of plants is ranged in the fourth section of Linnæus's nineteenth class, intitled Syngenesia Polygamia Necessaria, the flowers being composed of hermaphrodite florets in the disk, which are barren, and female florets which are fruitful.

The SPECIES are,

1. OSTEOSPERMUM (*Moniliferum*) foliis ovalibus ferratis petiolatis subdecurrentibus. Lin. Hort. Cliff. 424. Hard-seeded Chrysanthemum, with oval sawed leaves on running foot-stalks. Chrysanthemoides Afrum populi albæ foliis. Hort. Elth. 80. tab. 68. Hard-seeded African Chrysanthemum, with leaves like those of the white Poplar.
2. OSTEOSPERMUM (*Pissiferum*) foliis lanceolatis acutè dentatis, caule fruticoso. Tab. 194. fig. 1. Hard-seeded Chrysanthemum, with spear-shaped leaves which are acutely indented, and a shrubby stalk.

3. OSTEOSPERMUM (*Spinosum*) spinis ramosis. Lin. Hort. Cliff. 424. Hard-seeded Chrysanthemum, with branching spines. Chrysanthemoides Osteospermum Africanum odoratum, spinosum & viscosum. Hort. Amst. 2. p. 85. Hard-seeded Chrysanthemum of Africa, which is prickly, viscous, and sweet.

4. OSTEOSPERMUM (*Polygaloides*) foliis lanceolatis imbricatis sessilibus. Flor. Leyd. Prod. 179. Hard-seeded Chrysanthemum, with spear-shaped leaves sitting close to the stalks, and lying over each other like the scales of a fish. Monilifera polygoni foliis. Vaill. Act. Par. 1720. Monilifera with Knot Grass leaves.

The first sort grows naturally at the Cape of Good Hope, but has been several years an inhabitant in the English gardens. This rises with a shrubby stalk seven or eight feet high, covered with a smooth gray bark, and divides into several branches, garnished with oval leaves, which are unequally indented on their edges; they are placed alternately, and are of a thick consistence, covered with a hoary down, which goes off from the older leaves. The flowers are produced in clusters at the end of the branches, six or eight coming out together, upon foot-stalks an inch and a half long; these are yellow, and shaped like those of Ragwort. The border or rays are composed of about ten half florets, which spread open; the disk or middle is composed of tubulous florets, which are cut into five parts at the brim; these are barren, but the half florets round the border, have one hard seed succeeding each of them. This plant flowers but seldom here; the time of its flowering is in July or August.

The second sort grows like the first, but the leaves are more pointed, of a green colour, and acutely sawed on the edges; the foot-stalks of the leaves are bordered, and the leaves are deeply veined. This produces tufts of yellow flowers at the extremity of the shoots from spring to autumn, and frequently ripens seeds.

The third sort is a low shrubby plant, which seldom rises above three feet high, and divides into many branches; the ends of the shoots are beset with green branching spines; the leaves are very clammy, especially in warm weather; these are long and narrow, and set on without any order. The flowers are produced singly at the ends of the shoots, which are yellow, and appear in July and August.

These three sorts are too tender to live in the open air in England, so are placed in the green-house in October, and may be treated in the same manner as Myrtles, and other hardy green-house plants, which require a large share of air in mild weather; and in the beginning of May the plants may be removed into the open air, and placed in a sheltered situation during the summer season. The second and third sorts must have plenty of water, being very thirsty plants.

These plants are propagated by cuttings, which may be planted in any of the summer months, upon a bed of light earth, and should be watered and shaded until they have taken root, which they will be in five or six weeks, when they must be taken up and planted in pots; for if they are suffered to stand long, they will make strong vigorous shoots, and will be difficult to transplant afterward, especially the first and second sorts; but there is not so much danger of the third, which is not so vigorous, nor so easy in taking root as the other. During the summer season the pots should be frequently removed, to prevent the plants from rooting through the holes in the bottom of the pots into the ground, which they are very apt to do when they continue long undisturbed, and then they shoot very luxuriantly; and, on their being removed, these shoots, and sometimes the whole plants, will decay.

The fourth sort grows naturally at the Cape of Good Hope; this hath a shrubby stalk about four feet high, which divides into many small branches, garnished with small oblong leaves which sit close to them, and in some of the upper branches they lie over each other like the scales of fish. The flowers come out

at the end of the branches, standing singly upon foot-stalks, which are about an inch long; the half florets which compose the border or rays, are acute-pointed and spread open; the disk is composed of florets which are barren. This sort is propagated by cuttings, in the same manner as the other sorts, and must be treated in the same way.

OSYRIS. Lin. Gen. Plant. 978. Casia. Tourn. Inst. R. H. 664. tab. 488. Poets Casia.

The CHARACTERS are,

It is male and female in different plants; the empalement of the flower is of one leaf, which is divided into three acute segments. The flower hath no petals, but those on the male plants have three short stamina; the female have a germen, which afterward changes to a globular berry, having a single seed.

We know but one SPECIES of this plant, viz.

OSYRIS (*Alba*) frutescens baccifera. C. B. P. Shrubby berry-bearing Poets Casia; and by some, red-berried shrubby Casia.

This is a very low shrub, seldom rising above two feet high, having ligneous branches, which are garnished with long narrow leaves, of a bright colour. The flowers appear in June, which are of a yellowish colour, and are succeeded by berries, which at first are green, and afterward turn to a bright red colour, somewhat like those of Asparagus.

This plant grows wild in the south of France, in Spain, and some parts of Italy, by the side of roads, as also between the rocks, but is with great difficulty transplanted into gardens; nor does it thrive after being removed, so that the only method to obtain this plant is, to sow the berries where they are to remain. These berries commonly remain a year in the ground before the plants appear, and sometimes they will lie two or three years, so that the ground should not be disturbed under three years, if the plants do not come up sooner. These seeds must be procured from the places where the plants naturally grow, for those which have been brought into gardens never produce any, and it is with great difficulty they are preserved alive.

OTHONNA. Lin. Gen. Plant. 888. Doria. Raii Meth Plant. 33. Jacobæa. Tourn. Inst. R. H. 485. tab. 276. Ragwort.

The CHARACTERS are,

It hath a radiated flower, composed of hermaphrodite florets which form the disk, and female half florets which form the rays or border; these are included in one common single empalement of one leaf, cut into eight or ten segments. The hermaphrodite flowers are tubulous, indented at the top in five parts; the female half florets are stretched out like a tongue, and the point has three indentures which are reflexed. The hermaphrodite florets have short hairy stamina, terminated by cylindrical summits, and an oblong germen supporting a slender style, crowned by a single stigma. The female half florets have oblong germen with a slender style, crowned by a large bifid reflexed stigma. The hermaphrodite florets are seldom fruitful, but the female half florets have an oblong seed, which is sometimes naked, and at others crowned with down; these sit in the permanent empalement.

This genus of plants is ranged in the fourth section of Linnaeus's nineteenth class, which includes the plants with compound flowers, whose female flowers are fruitful and the hermaphrodite barren.

The SPECIES are,

1. OTHONNA (*Coronopifolia*) foliis infimis lanceolatis integerrimis, superioribus sinuato-dentatis. Hort. Cliff. 419. *Othonna with spear-shaped lower leaves which are entire; and the upper ones indented in sinuses.* Jacobæa Africana frutescens coronopi folio. Hort. Amst. 2. p. 139. *Shrubby African Ragwort, with a Hartshorn leaf.*
2. OTHONNA (*Calthoides*) foliis cuneiformibus integerrimis sessilibus, caule fruticoso procumbente, pedunculis longissimis. *Othonna with entire wedge-shaped leaves sitting close, a shrubby trailing stalk, and very long foot-stalk, to the flowers.* Calthoides Africana, glastifolio. Juss. *African Bastard Marygold, with a Wood leaf.*
3. OTHONNA (*Pectinata*) foliis pinnatifidis, laciniis line-

aribus parallelis. Hort. Cliff. 419. *Othonna with wing-pointed leaves, whose segments are narrow and parallel.* Jacobæa Africana frutescens, foliis absinthii umbelliferi incanis. Hort. Amst. 2. p. 137. tab. 69. *Shrubby African Ragwort, with hoary leaves like those of the umbelliferous Wormwood.*

4. OTHONNA (*Abrotanifolia*) foliis multifido-pinnatis linearibus. Flor. Leyd. Prod. 380. *Othonna with very narrow leaves, ending in many winged points.* Jacobæa Africana frutescens, foliis abrotani, sc. crithmi major & minor. Volk. Norim. 225. *Shrubby African Ragwort, with a Southernwood or Samphire leaf.*

5. OTHONNA (*Bulbosa*) foliis ovato-cuneiformibus dentatis. Lin. Sp. Plant. 926. *Othonna with oval, wedge-shaped, indented leaves.* Solidago foliis oblongis dentatis glabris, floribus magnis umbellatis. Burm Afr. 164. tab. 59. *Woundwort with oblong, indented, smooth leaves, and large flowers growing in umbels.*

The first sort grows naturally in Æthiopia. This rises with a shrubby stalk four or five feet high, dividing into several branches, garnished with grayish leaves placed without order, those on their lower part being narrow and entire, but the others are indented on the edges after the manner of Hartshorn. The flowers are produced in loose umbels at the end of the branches; they are yellow, and are succeeded by downy seeds.

The second sort was discovered by the late Dr. Shaw, growing naturally near Tunis in Africa, from whence he brought the seeds. This sends out many ligneous stalks from the root, which spreads out on every side, declining toward the ground, garnished with grayish leaves, which are narrow at their base, enlarging upward, and are broad at their points, where they are rounded; these sit close to the stalks. The flowers are produced upon long, thick, succulent foot-stalks at the end of the branches; they are yellow; the rays are sharp-pointed, and not much longer than the empalement; the disk is large, and the florets are as long as the empalement; the seeds are crowned with a long down.

The third sort grows naturally at the Cape of Good Hope, from whence the seeds were brought to Holland, and the plants were raised in the Amsterdam Garden in 1699. This rises with a shrubby stalk about the thickness of a man's thumb, two or three feet high, which divide into many branches, covered with a hoary down, and garnished with hoary leaves about three inches long and one broad, cut into many narrow segments almost to the midrib; these segments are equal and parallel, and are indented at their ends into two or three points. The flowers are produced on long foot-stalks which arise from the wings of the stalks; toward the end of the branches they have large yellow rays, or borders, with a disk of florets, and are succeeded by oblong purple seeds crowned with down.

The fourth sort grows naturally on the hills near the Cape of Good Hope, and was raised from seed in the Amsterdam Garden. This hath a low, shrubby, branching stalk; the leaves are thick like those of Samphire, and are cut into many narrow segments. The flowers are produced on short foot-stalks at the end of the branches; they are yellow, and shaped like the other species of this genus, and are succeeded by brown seeds crowned with soft down.

The fifth sort grows naturally at the Cape of Good Hope. This hath a thick shrubby stalk, dividing into several branches which rise five or six feet high; the leaves come out in clusters from one point, spread on every side; they are smooth, narrow at their base, enlarging gradually to their points, which are rounded; their edges are acutely indented like those of the Holly. From the center of the leaves arise the foot-stalks of the flowers, which are five or six inches long, branching out into several smaller, each sustaining one yellow radiated flower, shaped like the former; these are succeeded by slender seeds crowned with down.

The first, second, third, fourth and fifth sorts, are preserved in green-houses through the winter, but require

quire no artificial warmth; if these are protected from the frost it is sufficient, and in mild weather they must have a large share of free air. In the summer they must be placed abroad in a sheltered situation, among other hardy exotic plants, where they will add to the variety, and flower great part of the season. These may be all propagated by cuttings during the summer months, which should be planted upon an old hot-bed, and covered with glasses, shading them from the sun in the heat of the day. When these have taken root, they should be planted each into a separate pot filled with soft loamy earth, placing them in the shade till they have taken new root; then they may be removed to a sheltered situation, where they may remain till autumn, treating them in the same way as the old plants.

The second sort will live in the open air if it is planted in a warm situation and a dry soil. Some of these plants have endured the open air for more than twenty years in the Chelsea Garden, without protection. This is easily propagated by cuttings, in the same way as the former.

OXALIS. Lin. Gen. Plant. 515. Oxys. Tourn. Inst. R. H. 88. tab. 19. Wood-sorrel.

The CHARACTERS are,

The empalement of the flower is short, permanent, and cut into five acute segments. The flower is of one petal, cut into five obtuse indented segments almost to the bottom; it hath ten erect hairy stamina, terminated by roundish furrowed summits, and a germen with five angles, supporting five slender styles, crowned by obtuse stigmas. The germen afterward becomes a five-cornered capsule with five cells, which open longitudinally at the angles, containing roundish seeds, which are thrown out with an elasticity on the touch when ripe.

This genus of plants is ranged in the fifth section of Linnaeus's tenth class, which includes those plants whose flowers have ten stamina and five styles.

The SPECIES are,

1. OXALIS (*Acetosella*) scapo unifloro, foliis ternatis, radice squamoso-articulata. Hort. Cliff. 175. *Wood-sorrel with one flower on a foot-stalk, trifoliate leaves, and a scaly jointed root.* Oxys flore albo. Tourn. Inst. 88. *Wood-sorrel with a white flower.*
2. OXALIS (*Corniculata*) caule ramoso diffuso, pedunculis umbelliferis. Hort. Cliff. 175. *Wood-sorrel with a branching diffused stalk, and umbellated foot-stalks.* Oxys lutea. J. B. *Yellow Wood-sorrel.*
3. OXALIS (*Striata*) caule ramoso erecto, pedunculis umbelliferis. Flor. Virg. 161. *Wood-sorrel with a branching upright stalk, and umbellated foot-stalks.* Oxys lutea, Americana, erectior. Tourn. Inst. R. H. 88. *Upright, yellow, American Wood-sorrel.*
4. OXALIS (*Incarinata*) caule subramoso bulbifero, pedunculis unifloris, foliis passim verticillatis foliolis obcordatis. Lin. Sp. 622. *Wood-sorrel with branching stalks bearing bulbs, the leaves generally in whorls, and the small leaves heart-shaped.* Oxys bulbosa Æthiopica minor, folio cordato, flore ex albido purpurascens. Tourn. Inst. 89. *Smaller bulbous Ethiopian Wood-sorrel, with a heart-shaped leaf, and a purplish white flower.*
5. OXALIS (*Purpurea*) scapo unifloro, foliis ternatis, radice bulbosa. Hort. Cliff. 175. *Wood-sorrel with a foot-stalk supporting one flower, trifoliate leaves, and a bulbous root.* Oxys bulbosa Africana, rotundifolia, caulibus & floribus purpureis amplis. Hort. Amst. 1. p. 41. tab. 21. *African bulbous Wood-sorrel, having a round leaf, and large purple stalks and flowers.*
6. OXALIS (*Pesc-capræ*) scapo umbellifero, foliis ternatis bipartitis. Lin. Sp. Plant. 434. *Wood-sorrel with an umbelliferous stalk, and trifoliate leaves divided in two parts.* Oxalis bulbosa pentaphylla & hexaphylla, floribus magnis luteis & copiosis. Burm. Afr. 80. tab. 29. *Bulbous Wood-sorrel with five or six leaves, and large yellow flowers in abundance.*
7. OXALIS (*Frutescens*) caule erecto fruticoso, foliis ternatis, impari maximo. *Wood-sorrel with an upright shrubby stalk, and trifoliate leaves, the middle one being very large.* Oxys lutea frutescens, trifolii bituminosi facie. Plum. Cat. 2. *Yellow shrubby Wood-sorrel, with the appearance of bituminous Trefoil.*

8. OXALIS (*Barbeleri*) caule ramoso erecto, pedunculis bifidis racemiferis. Lin. Sp. 624. *Wood-sorrel with an erect branching stalk, and branching bifid foot-stalks.* Trifolium acetosum Americanum, rubro flore. Barrel. Rar. 64. *Three-leaved American Wood-sorrel, with a red flower.* The first sort grows naturally in moist shady woods, and close to hedges in most parts of England, so is but seldom admitted into gardens; though whoever is fond of acid herbs in fallads, can scarce find a more grateful acid in any other plant. The roots of this sort are composed of many scaly joints, which propagate in great plenty. The leaves arise immediately from the roots upon single long foot-stalks, are composed of three heart-shaped lobes, which meet in a center, where they join the foot-stalk; they are of a pale green and hairy; between these come out the flowers upon pretty long foot-stalks, each sustaining one large white flower of the open bell shape. These appear in April and May, and are succeeded by five-cornered oblong seed-vessels having five cells, inclosing small brownish seeds; when these are ripe, the seed-vessels burst open at the least touch, and cast out the seeds to a considerable distance. This is the sort which is directed for medicinal use in the dispensaries; but those people who supply the market with herbs, generally bring the third sort, which is now become common in the gardens; but this hath very little acid, so is unfit for the purposes of the other; but as it rises with an upright branching stalk, so it is soon gathered and tied up in bunches; whereas the leaves of the first grow singly from the root, and require more time in gathering. There is a variety of the first sort with a purplish flower, which grows naturally in the North of England, but, as it does not differ from it in any other respect, I have not enumerated it.

The second sort is an annual plant, which grows naturally in woods and shady places in Italy and Sicily. The root of this is long, slender, and fibrous; the stalks trail upon the ground, spreading out eight or nine inches wide on every side, dividing into small branches; the leaves stand upon pretty long foot-stalks, and are composed of three heart-shaped lobes, which have deeper indentures at their points than those of the first sort. The flowers are yellow, growing in form of an umbel, upon pretty long slender foot-stalks, arising from the side of the branches. These appear in June and July, and are succeeded by seed-vessels near an inch long, which open with an elasticity, and cast out the seeds.

The third sort grows naturally in Virginia and other parts of North America, from whence the seeds were formerly brought to Europe; but wherever this plant has been once introduced and suffered to ripen seeds, it has become a common weed. This is an annual plant, rising with a branching herbaceous stalk eight or nine inches high; the leaves stand upon very long foot-stalks, and are shaped like those of the second sort. The flowers are yellow, standing in a sort of umbel, upon long, slender, erect foot-stalks; the seed-vessels and seeds are like those of the second sort.

These three sorts require no particular culture; if the roots of the first sort are taken up and transplanted in a shady moist border, they will thrive and multiply exceedingly; and if they are kept clean from weeds, will require no other care. If the seeds of the other two sorts are sown in an open border, the plants will rise freely, and require no care; for if they are permitted to scatter their seeds, there will be a plentiful supply of the plants.

The fourth sort hath a roundish bulbous root, from which come out slender stalks about six inches high, which divide into branches by pairs, and from the divisions come out the foot-stalks of the leaves; these are long, slender, and sustain a trifoliate leaf composed of three small, roundish, heart-shaped lobes. The foot-stalks of the flowers are long, slender, and arise from the division of the stalks, each sustaining one purplish flower about the same size and shape as those of the first sort. This flowers in May, June, and July, and sometimes produces ripe seeds in England. It grows naturally at the Cape of Good Hope, so is too tender

O X M

to live through the winter in the open air in England; but if it is sheltered from hard frost under a common hot-bed frame in winter, it will require no other protection. It propagates in plenty by offsets from the root, as also by bulbs, which come out from the side of the stalks.

The fifth sort grows naturally at the Cape of Good Hope in such plenty, that the earth which came from thence, in which some plants were brought to England, was full of it. This hath a roundish bulbous root, covered with a brown skin, sending out strong fibres which strike deep into the ground; the leaves are trifoliate, composed of three roundish, large, hairy lobes, which are but little indented at the top; these stand upon long slender foot-stalks, which arise from a thick short stalk, which adheres to the root. The foot-stalks of the flowers arise between the leaves from the stalk, each supporting one large purple flower; these appear in January and February, but are rarely succeeded by seeds here, but the roots put out offsets in great plenty, whereby it is propagated. This sort will not thrive in winter in the open air here, so the roots should be planted in pots, which may be sheltered under a common frame in winter, where it may have as much free air as possible in mild weather, otherwise the leaves will draw up weak; for the leaves of this plant come out in October, and continue growing till May, when they begin to wither and decay. The roots may be transplanted any time after the leaves decay, till they begin to push out again.

The sixth sort is a native of the same country as the fifth; the roots of this are bulbous; the leaves stand upon long slender foot-stalks, which arise from a short stalk or head; they are composed of three lobes, which are for the most part divided into two parts almost to their base. The foot-stalks of the flowers are five or six inches long, sustaining several large yellow flowers ranged in form of an umbel. These appear in March, and are sometimes succeeded by seeds here. This sort requires the same treatment as the fifth.

The seventh sort was discovered by Plumier in some

O X Y

of the French colonies in America, and was since found growing plentifully at La Vera Cruz by the late Dr. Houstoun, who sent it to England. This rises with a shrubby stalk a foot and a half high, sending out several slender branches, which are garnished with trifoliate small leaves, composed of three oval lobes, the middle one being twice as large as the side ones. These are placed by pairs opposite, and sometimes by threes round the stalk, standing upon short foot-stalks. The foot-stalks of the flowers arise from the wings of the stalks, are near two inches long, each sustaining four or five yellow flowers, whose petals are not much longer than the empalement; each of these have a smaller foot-stalk which is crooked, so that the flowers hang downward.

This sort is much tenderer than either of the former, so requires to be placed in a stove kept to a moderate degree of warmth in winter. It is propagated by seeds, which must be sown in pots, and plunged into a moderate hot-bed; and when the plants come up, they should be each planted into a separate pot filled with light sandy earth, and plunged into a fresh hot-bed, shading them from the sun till they have taken new root; after which they must be treated in the same manner as other tender plants from the same country.

The eighth sort grows naturally in the Brazils; for in a tub of earth which came from thence, the plants came up in plenty. This seldom rises more than three or four inches high, having upright stalks; the leaves are composed of three pretty large hairy lobes, standing on long foot-stalks. The flowers rise immediately from the root, having foot-stalks the same length with those of the leaves; they are bifid, supporting two pretty large red flowers, which are succeeded by oblong capsules filled with brown seeds.

This sort may be propagated by offsets from the root, or by seeds, and requires the same protection as the sixth sort.

P A D

PADUS. Lin. Gen. Edit. prior. 476. Edit. 5. Prunus. 546. Cerasus & Laurocerasus. Tourn. Inst. R. H. 625, 627. tab. 401, 403. The Bird-cherry, or Cherry Laurel.

The CHARACTERS are,

The empalement of the flower is bell-shaped, of one leaf, indented in five parts at the brim, which spread open. The flower hath five large roundish petals, which spread open, and are inserted in the empalement. It hath from twenty to thirty axil-shaped stamina, which are inserted in the empalement, terminated by roundish summits, and a roundish germen supporting a slender style, crowned by an entire obtuse stigma. The germen afterward becomes a roundish fruit, inclosing an oval-pointed nut having rough furrows.

This genus of plants was by Dr. Linnæus, in the former editions of his Method, separated from the Cherries, to which they had been before joined, because the furrows of the nuts in this genus were obtuse, whereas those of the Cherries are acute; but there is a more obvious distinction between them, which is, the flowers of the Padus are ranged in a long bunch (or racemus) and those of the Cherry have their foot-stalks arising from one joint; but in the last edition of his Method, he has joined this genus, the Cherry and Apricot, to the Plumb, making them only species of

P A D

the same genus; in which, I think, he has exceeded the boundaries of nature; for although the Padus and Cerasus may with propriety be joined in the same genus, yet these ought by no means to be joined to the Prunus; for it is well known, that the Cherry will not grow by grafting or budding upon the Plumb stock, nor the Plumb upon Cherry stocks, though there are no instances of two trees of the same genus, which will not grow upon each other, however different their exterior appearance may be.

It is ranged in the first section of Linnæus's twelfth class, which includes those plants whose flowers have from twenty to thirty stamina, which are either inserted in the empalement or petals of the flower, and but one style.

The SPECIES are,

1. PADUS (*Avium*) glandulis duobus, basi foliorum subjectis. Hort. Cliff. 185. *Bird-cherry with two glands at the base of the leaves.* Cerasus racemosa, sylvestris, fructu non eduli. C. B. P. 451. *Branching wild Cherry with a fruit not eatable.*
2. PADUS (*Rubra*) foliis lanceolato-ovatis deciduus, petiolis biglandulosus. tab. 196. fol. 2. *Bird-cherry with spear-shaped, oval, deciduous leaves, whose foot-stalks have two glands.* Cerasus racemosa sylvestris, fructu non eduli

eduli rubro. H. R. Par. *Branching wild Bird-cherry with a red fruit, which is not eatable, and commonly called by the gardeners, Cornish Cherry.*

3. PADUS (*Virginiana*) foliis oblongo-ovatis serratis acuminatis deciduis, basi antice glandulosis. *Bird-cherry with oblong, oval, sawed, acute-pointed, deciduous leaves, and glands on the fore part of the foot-stalk. Cerasi similis arbutcula Mariana, padi folio, flore albo parvo racemoso. Pluk. Mant. 43. Catesb. Car. 1. p. 28. American Bird-cherry.*

4. PADUS (*Laurocerasus*) foliis sempervirentibus lanceolato-ovatis. Hort. Cliff. 42. *Bird-cherry with evergreen, spear-shaped, oval leaves. Laurocerasus. Clus. Hist. 1. p. 4. The common Laurel.*

5. PADUS (*Lusitanica*) foliis oblongo-ovatis sempervirentibus eglandulosis. *Bird-cherry with oblong, oval, evergreen leaves, having glands. Laurocerasus Lusitanica minor. Tourn. Inst. 628. Smaller Portugal Laurel, called Aserero by the Portuguese.*

6. PADUS (*Caroliniana*) foliis lanceolatis acutè denticulatis sempervirentibus. *Evergreen Bird-cherry with spear-shaped leaves, having small acute indentures, called in America Bastard Mahogany.*

The first sort grows naturally in the hedges in Yorkshire, and many of the northern counties in England, as also in some few places near London, but it is propagated as a flowering-shrub in the nursery-gardens for sale. This rises with several woody stalks to the height of ten or twelve feet, which will grow to have stems nine or ten inches diameter, if they are permitted to stand; but as the fashions of gardens have been frequently altering for fifty or sixty years past, so there are few places where any of the ornamental flowering trees have been suffered to remain. The branches of this tree grow wide and scattering; they are covered with a purplish bark, and garnished with oval spear-shaped leaves placed alternate, which are slightly sawed on their edges, and have two small protuberances or glands at their base. The flowers are produced in long loose bunches from the side of the branches; they have five roundish white petals, which are much smaller than those of the Cherry, and are inserted in the border of the empalement; and within these are a great number of stamina, which also are inserted in the empalement. The flowers stand each upon a short foot-stalk, and are ranged alternately along the principal foot-stalk; they have a strong scent, which is very disagreeable to most persons. These flowers appear in May, and are succeeded by small roundish fruit, which are first green, afterward turn red, and when ripe, are black, inclosing a roundish furrowed stone or nut, which ripens in August.

The second sort grows naturally in Armenia, from whence I have received the seeds; but it has been many years ago propagated in the nursery-gardens about London, where it is generally called Cornish-cherry. This sort has been often confounded with the first; many of the late writers in botany have supposed it was the same species, but I have raised both sorts from seeds, and have always found the young plants to retain their difference. This rises with a strait upright stem more than twenty feet high; the branches are shorter, and grow closer together than those of the first, so naturally form regular heads; the leaves of this are shorter and broader than those of the other, and are not so rough; the flowers grow in closer shorter spikes, which stand more erect; the fruit is larger, and red when ripe. This flowers a little after the first sort.

The third sort grows naturally in Virginia, and other parts of North America. This rises with a thick stem from ten to thirty feet high, dividing into many branches, which have a dark purple bark, and are garnished with oval leaves placed alternately on short foot-stalks; they are of a lucid green, and slightly sawed on their edges, continuing in verdure as late in the autumn as any of the deciduous trees. The flowers come out in bunches like those of the second sort, and are succeeded by larger fruit, which is black when ripe, and is soon devoured by the birds. The

wood of this tree is beautifully veined with black and white, and will polish very smooth, so is frequently used for cabinet work; as is also the wood of the first sort, which is much used in France, where it is called, *Bois de Sainte-Lucie.*

The fourth sort is the common Laurel, which is now so well known as to need no description. This grows naturally about Trebifond, near the Black Sea, and was brought to Europe about the year 1576, but is now become very common, especially in the warmer parts of Europe.

The fifth sort was brought to England from Portugal, but whether it is a native of that country, or was introduced there from some other country, is hard to determine. The Portuguese call it Aseraro, or Azerero. This was supposed to have been but a low evergreen shrub, but by experience we find, that when it is in a proper soil, it will grow to a large size. There are at present some of the trees whose trunks are more than a foot diameter, and twelve or sixteen feet high, which are not of many years standing, and are well furnished with branches, which when young have a reddish bark; the leaves are shorter than those of the common Laurel, approaching nearer to an oval form; they are of the same consistence, and of a lucid green, which mixing with the red branches, make a beautiful appearance. The flowers are produced in long loose spikes from the side of the branches; they are white, and shaped like those of the common Laurel, appearing in June, and are succeeded by oval berries smaller than those of the common Laurel; they are first green, afterward red, and when ripe are black, inclosing a stone like the Cherry.

The seeds of the sixth sort were sent from Carolina, by the title of Bastard Mahogany, from the colour of the wood, which is somewhat like Mahogany. This seems to be little more than a shrub, if we may judge from its growth here; the stalk does not rise more than three feet high, but sends out lateral branches, which spread on every side, covered with a brown bark, and garnished with spear-shaped leaves near two inches long, and three quarters of an inch broad, with small acute indentures on the edges; they stand alternately upon very short foot-stalks, and are of a lucid green, continuing their verdure all the year. This has not as yet flowered in England, so I can give no account of it; but by the seeds and description which I received of its flowers, it belongs to this genus.

This plant will live in the open air here, if it is planted in a warm situation, and sheltered in severe frost, to which, if they are exposed, often destroys them, especially while the plants are young; but when they have acquired strength, there is no doubt of their thriving very well in the open ground in sheltered situations. It may be propagated in the same manner as the Portugal Laurel from the berries; and if the branches are laid down they will take root, but the cuttings will not grow, so far as I have experienced. The three first sorts are easily propagated, either by the seeds or layers; when they are propagated by the seeds they should be sown in the autumn, for if they are kept out of the ground till spring, they seldom grow till the second year. These may be sown upon a bed or border of good ground, in the same way as the Cherry-stones which are designed for stocks; and the young plants may be treated in the same manner, planting them out in a nursery, where they may stand two years to get strength, and then they may be transplanted to the places where they are to remain. They are usually intermixed with other flowering shrubs, in wilderness work, where they add to the variety.

If they are propagated by layers, the young shoots should be laid down in the autumn, which will have good roots by that time twelvemonth, when they may be separated from the old plants, and transplanted into a nursery for a year or two to get strength, and may then be removed to the places where they are to grow.

The third sort will grow to be a very large tree when it is planted in a moist soil, but in dry ground it rarely rises to be more than twenty feet high. There have been some plants of late years raised from seeds which came from Carolina, which have all the appearance of the third sort, but are of much humbler growth; whether this may proceed from their being brought from a warmer climate, so do not agree with the cold of our winters so well as that, or whether they are a different species from that, I cannot yet determine, as they have not produced fruit here.

The Laurel may be easily propagated by planting of the cuttings; the best time for doing this is in September, as soon as the autumnal rains fall to moisten the ground; the cuttings must be the same year's shoots, and if they have a small part of the former year's wood to their bottom, they will more certainly succeed, and form better roots. These should be planted in a soft loamy soil about six inches deep, pressing the earth close to them. If these are properly planted, and the ground is good, there will few of the cuttings fail; and if they are kept clean from weeds the following summer, they will have made good shoots by the following autumn, when they may be transplanted into a nursery, where they may grow two years to get strength, and then should be removed to the places where they are to remain. These plants were formerly kept in pots and tubs, and preserved in green-houses in winter; but afterward they were planted against warm walls, to preserve them, being frequently injured by severe frost. After this the plants were trained into pyramids and globes, and constantly kept sheered; by which the broad leaves were generally cut in the middle, which rendered the plants very unsightly. Of late years they have been more properly disposed in gardens, by planting them to border woods, and the sides of wilderness quarters; for which purpose we have but few plants so well adapted, for it will grow under the drip of trees, in shade or sun; and the branches will spread to the ground, so as to form a thicket; and the leaves being large, and having a fine glossy green colour, they set off the woods and other plantations in winter, when the other trees have cast their leaves; and in summer they make a good contrast with the green of the other trees. These trees are sometimes injured in very severe winters, especially where they stand single and are much exposed; but where they grow in thickets, and are screened by other trees, they are seldom much hurt; for in those places it is only the young tender shoots which are injured, and there will be new shoots produced immediately below these to supply their place, so that in one year the damage will be repaired. But whenever such severe winters happen, these trees should not be cut or pruned till after the following Midsummer; by which time it will appear what branches are dead, which may then be cut away, to the places where the new shoots are produced; for by hastily cutting these trees in the spring, the drying winds have free ingress to the branches, whereby the shoots suffer as much, if not more, than they had done by the frost.

These trees are also very ornamental, when they are mixed with other evergreen trees, in forming of thickets, or to shut out the appearance of disagreeable objects; for the leaves being very large, make a very good blind, and are equally useful for screening from winds; so that when they are planted between flowering-shrubs, they may be trained so as to fill up the vacancies in the middle of such plantations; and will answer the purpose of screening in the winter, and shutting out the view through the shrubs in all seasons: there are also many other purposes to which this tree may be applied, so as to render it very ornamental.

In warmer countries this tree will grow to a large size, so that in some parts of Italy there are large woods of them; but we cannot hope to have them grow to so large stems in England; for should these trees be pruned up, in order to form them into stems,

the frost would then become much more hurtful to them than in the manner they usually grow, with their branches to the ground: however, if the trees are planted pretty close together in large thickets, and permitted to grow rude, they will defend each other from the frost, and they will grow to a considerable height: an instance of which is now in that noble plantation of evergreen trees, made by his Grace the Duke of Bedford at Wooburn-abbey, where there is a considerable hill covered entirely with Laurels; and in the other parts of the same plantation, there are great numbers of these intermixed with the other evergreen trees, where they are already grown to a considerable size, and make a noble appearance.

There are some persons who propagate these trees from their berries, which is certainly the best way to obtain good plants; for those which come from seeds have a disposition to an upright growth, whereas almost all those which are raised from cuttings or layers, incline more to an horizontal growth, and produce a greater number of lateral branches. When any person is desirous to propagate this tree by seeds, the berries must be guarded from the birds, otherwise they will devour them before they are perfectly ripe, which is seldom earlier than the latter end of September, or the beginning of October, for they should hang until the outer pulp is quite black. When these berries are gathered, they should be sown soon after; for when they are kept out of the ground till spring, they frequently miscarry; and there will be no hazard in sowing them in the autumn, provided they are put in a dry soil; and if the winter should prove severe, the bed in which they are sown should be covered with rotten tan, straw, Peas-haulm, or any light covering, to prevent the frost from penetrating of the ground. The best way will be to sow the berries in rows at about six inches distance, and one inch asunder in the rows; if drills are made about three inches deep, and the berries scattered in them, and the earth drawn over them, it will be a very good method. The following spring the plants will appear, when they should be kept clean from weeds; and if the season should prove dry, if they are duly watered, the plants will make so good progress as to be fit for transplanting the following autumn, when they should be carefully taken up, and planted in a nursery, placing them in rows at three feet asunder, and the plants one foot distance in the rows. In this nursery they may remain two years, by which time they will be fit to transplant where they are designed to remain.

The best season for transplanting these plants is in the autumn, as soon as the rain has prepared the ground for planting; for although they often grow when removed in the spring, yet those do not take so well, nor make so good progress as those which are removed in the autumn, especially if the plants are taken from a light soil, which generally falls away from their roots; but if they are taken up with balls of earth to their roots, and removed but a small distance, there will be no danger of transplanting them in the spring, provided it is done before they begin to shoot; for as the plants will shoot very early in the spring, so if they are removed after they have shot, the shoots will decay, and many times the plants entirely fail.

There are some persons who, of late, have banished these plants from their gardens, as supposing them possessed of a poisonous quality, because the distilled water has proved so in many instances; but however the distilled water may have been found destructive to animals, yet from numberless experiments which have been made both of the leaves and fruit, it hath not appeared that there is the least hurtful quality in either; so that the whole must be owing to the oil, which may be carried over in distillation.

The berries have been long used to put into brandy, to make a sort of ratafia, and the leaves have also been put into custards, to give them an agreeable flavour; and although these have been for many years much used, yet there hath been no one instance of their

P Æ O

their having done the least injury ; and as to the berries, I have known them eaten in great quantities without prejudice.

There are some persons who have grafted the Laurel upon Cherry stocks, with design to enlarge the trees, but although they will take very well upon each other, yet they seldom make much progress when either the Laurel is grafted on the Cherry, or the Cherry upon the Laurel ; so that it is only a thing of curiosity, attended with no real use : and I would recommend to persons who have this curiosity, to graft the Laurel upon the Cornish Cherry, rather than any other sort of stock, because the graft will unite better with this ; and as it is a regular tree and grows large, so it will better answer the purpose of producing large trees.

The Portugal Laurel may be propagated in the same way as the common Laurel, either by cuttings, layers, or seeds. If the cuttings are planted at the same season, and in the same way as hath been directed for the common Laurel, they will take root very freely ; or if the young branches are laid in the autumn, they will take root in one year, and may then be removed into a nursery, where they may grow a year or two get strength, and then transplanted where they are to remain.

But although both these methods are very expeditious for the propagating these plants, yet I would recommend the raising them from the berries, especially where they are designed for tall standards ; for the plants which are propagated by cuttings and layers, put out more lateral branches and become bushy, but are not so well inclined to grow upright, as those which come from seeds : and as there are now many trees in the English gardens which produce plenty of berries every year, so if they are guarded from birds till they are ripe, there may be a supply of them sufficient to raise plants enough without propagating them any other way. These berries must be sown in the autumn, and treated in the same way as the common Laurel.

This tree delights in a gentle loamy soil, which is not too wet nor over dry, though it will grow upon almost any soil : but the plants do not make so great progress, nor appear so beautiful, when planted in a very dry soil, or in ground that is too wet. The time of transplanting this, is the same as for the common Laurel.

This tree is much hardier than the common Laurel, for in the severe frost of the year 1740, when great numbers of Laurels were entirely killed, and most of them lost their verdure, this remained unhurt in perfect verdure, which renders it more valuable ; and as by the appearance of some trees now growing in the gardens, they seem as if they will grow to a large size, so it is likely to be one of the most ornamental evergreens we have.

PÆONIA. Tourn. Inst. R. H. 273. tab. 146. Lin. Gen. Plant. 600. [so called from Pæon the physician, because he is said to have cured Pluto, when wounded by Hercules, with this herb.] The Peony ; in French, *Pivoine*.

The CHARACTERS are,

The flower has a permanent empalement, composed of five concave reflexed leaves, unequal in size and position. The flower hath five large, roundish, concave petals which spread open, and a great number of short hairy stamina, terminated by large, oblong, four-cornered summits, with two, three, or four oval, erect, hairy germen in the center, having no styles, but have oblong, compressed, obtuse, coloured stigmas. The germen afterward become so many oval, oblong, reflexed, hairy capsules, having one cell, open longitudinally, containing several oval, shining, coloured seeds, fixed to the furrow.

This genus of plants is ranged in the second section of Linnaeus's thirteenth class, which contains those plants whose flowers have many stamina and two germen or styles.

The SPECIES are,

1. PÆONIA (*Mascula*) foliis lobatis ex ovato-lanceolatis. Haller. Helv. 311. Peony with lobated leaves which are

P Æ O

oval and spear-shaped. Pæonia folio nigricante splendido, quæ mas. C. B. P. 323. Peony with dark shining leaves, otherwise male Peony.

2. PÆONIA (*Fœminea*) foliis difformiter lobatis. Haller. Helvet. 311. Peony with difformed lobated leaves. Pæonia communis, vel fœmina. C. B. P. 323. Common or female Peony.
3. PÆONIA (*Peregrina*) foliis difformiter lobatis, lobis incisis, petalis florum rotundioribus. Peony with difformed lobated leaves which are cut, and rounder petals to the flower. Pæonia peregrina, flore saturatè rubente. C. B. P. 324. Foreign Peony with a deep red flower.
4. PÆONIA (*Hirsuta*) foliis lobatis, lobis lanceolatis integerrimis. Peony with lobated leaves, whose lobes are spear-shaped and entire. Pæonia fœmina flore pleno rubro majore. C. B. P. 324. Female Peony with a larger double red flower.
5. PÆONIA (*Tartarica*) foliis difformiter lobatis pubescentibus. Tab. 199. Peony with difformed lobated leaves, which are downy.
6. PÆONIA (*Lusitanica*) foliis lobatis, lobis ovatis infernè incanis. Peony with lobated leaves, whose lobes are oval and hoary on their under side. Pæonia Lusitanica, flore simplici odoro. Juss. Peony of Portugal with a single sweet flower.

The first sort here enumerated, is the common male Peony, which grows naturally in the woods on the Helvetian mountains. The root of this is composed of several oblong knobs, shaped like the dugs of a cow, which hang by strings, fastened to the main head ; the stalks rise about two feet and a half high, which are garnished with leaves composed of several oval lobes, some of which are cut into two or three segments ; they are of a lucid green on their upper side, but are hoary on their under. The stalks are terminated by large single flowers, composed of five or six large roundish red petals, inclosing a great number of stamina, terminated by oblong yellow summits. In the center is situated two, three, or sometimes five germen, which join together at their base ; they are covered with a whitish hairy down ; these afterward spread asunder, and open longitudinally, exposing the roundish seeds, which are first red, then purple, and when perfectly ripe turn black. The flowers appear in May, and the seeds ripen in the autumn.

There is one variety of this with pale, and another with white flowers, as also one whose leaves have larger lobes ; but as these are generally supposed to be only feminal variations, so I have not enumerated them here.

The second sort is called the female Peony ; the roots of this are composed of several roundish thick knobs or tubers, which hang below each other, fastened with strings ; the stalks are green, and rise about the same height as the former ; these are garnished with leaves, composed of several unequal lobes, which are variously cut into many segments ; they are of a paler green than those of the first, and are hairy on their under side ; the flowers are smaller, and of a deeper purple colour. It flowers at the same time as the first.

There are several varieties of this sort with double flowers, which are cultivated in the English gardens ; these differ in the size and colour of their flowers, but are supposed to have been accidentally obtained from seeds.

The third sort grows naturally in the Levant ; the roots of this are composed of roundish knobs like those of the second sort, as are also the leaves, but are of a thicker substance ; the stalks do not rise so high, and the flowers have a greater number of petals. This flowers a little after the other. The large double purple Peony, I suspect is a variety of this sort.

The fourth sort hath roots like the second ; the stalks are taller, and of a purplish colour ; the leaves are much longer, the lobes are spear-shaped and entire ; the flowers are large, and of a deep red colour. This flowers at the same time as the two first sorts.

The

P Æ O

The seeds of the fifth sort were brought from the Levant, and from them there were plants raised, which produced single, and others with double flowers, of the same shape, size, and colour. The roots of these are composed of oblong fleshy tubers or knobs; they are of a pale colour, and hang by strings like the other species. The stalks rise about two feet high, which are of a pale green, and are garnished with leaves composed of several lobes, which are irregular in shape and size, some of them having but six, and others have eight or ten spear-shaped lobes; these are some cut into two, some three segments, and others are entire; they are of a pale green, and are downy on their under side. The stalks are terminated by one flower of a bright red colour, a little less than that of the female Peony, and have fewer petals; they have a great number of stamina, and sometimes two, at others three germen, like those of the female Peony, but shorter and whiter. This flowers a little later than the common Peony.

The seeds of the sixth sort were sent to the Chelsea Garden by Dr. de Jussieu, who brought them from Portugal, where the plants grow naturally. The root of this sort is not composed of roundish tubers or knobs, but hath two or three long, taper, forked fangs like fingers. The stalk rises little more than a foot high, and is garnished with leaves composed of three or four oval lobes, of a pale colour on their upper side, and hoary on their under; the stalk is terminated by a single flower, which is of a bright red colour, smaller than either of the former, and an agreeable sweet scent. This flowers about the same time with the common sort.

The first of these sorts is chiefly propagated for the roots, which are used in medicine; for the flowers being single, do not afford near so much pleasure as those with double flowers, nor will they abide near so long in beauty.

All the sorts with double flowers are preserved in curious gardens for the beauty of their flowers, which, when intermixed with other large growing plants in the borders of large gardens, will add to the variety; and the flowers are very ornamental in basons or flower-pots, when placed in rooms.

They are all extremely hardy, and will grow in almost any soil or situation, which renders them more valuable; for they will thrive under the shade of trees, and in such places they will continue much longer in beauty.

They are propagated by parting their roots, which multiply very fast. The best season for transplanting them is toward the latter end of August, or the beginning of September; for if they are removed after their roots have shot out new fibres, they seldom flower strong the succeeding summer.

In parting these roots, you should always observe to preserve a bud upon the crown of each offset, otherwise they will come to nothing; nor should you divide the roots too small (especially if you have regard to their blowing the following year) for when their offsets are weak, they many times do not flower the succeeding summer, or at least produce but one flower upon each root: but where you would multiply them in quantities, you may divide them as small as you please, provided there be a bud to each offset; but then they should be planted in a nursery-bed for a season or two to get strength, before they are placed in the flower-garden.

The single sorts may be propagated from seeds (which they generally produce in large quantities, where the flowers are permitted to remain) which should be sown in the autumn soon after they are ripe, upon a bed of light fresh earth, covering them over about half an inch thick with the same light earth. The spring following the plants will come up, when they should be carefully cleared from weeds, and in very dry weather refreshed with water, which will greatly forward their growth. In this bed they should remain two years before they are transplanted, observing in autumn, when the leaves are decayed, to spread

P A L

some fresh rich earth over the beds about an inch thick, and constantly to keep them clear from weeds. When you transplant them, (which should be done in September) you must prepare some beds of fresh light earth, which should be dug, and well cleaned from the roots of all noxious weeds; then plant the roots therein six inches asunder, and about three inches deep. In these beds they may remain until they flower, after which they may be transplanted where you design they should grow. It is very probable there may be some varieties obtained from the seeds of these plants, as is common in most other flowers; so that those which produce beautiful flowers, may be placed in the flower-garden, but such as continue single or ill coloured, may be planted in beds to propagate for medicinal use.

The Portugal Peony may also be propagated either by seeds, or parting the roots, in the same manner as the other sorts, but should have a lighter soil and a warmer situation. The flowers of this kind are single, but smell very sweet, which renders it worthy of a place in every good garden.

PALIURUS. Tourn. Inst. R. H. 616. tab. 387. Rhamnus. Lin. Gen. Plant. 235. Christ's Thorn.

The CHARACTERS are,

The flower has no empalement. It hath five petals which are ranged circularly, and end in acute points. It hath five stamina, which are inserted in the scales under the petals, terminated by small summits, and a roundish trifid germen, supporting three short styles, crowned by obtuse stigmas. The germen afterward becomes a buckler-shaped nut divided into three cells, each containing one seed.

This genus of plants is by Dr. Linnæus joined to the Rhamnus, which is ranged in the first section of his fifth class, in which are placed those plants whose flowers have five stamina and one style; but as the flowers of this have three styles, so it should be ranged in his third section.

We know but one SPECIES of this genus, viz.

PALIURUS (*Spina Christi.*) Dod. Pempt. 848. *Christ's Thorn.* Rhamnus aculeis geminatis, inferiore reflexo, floribus trigynis. Hort. Cliff. 69. *Prickly Buckthorn with double thorns, the under ones of which are reflexed, and flowers containing three germina.*

This plant grows naturally in the hedges in Palestine; it rises with a pliant shrubby stalk to the height of eight or ten feet, sending out many weak slender branches, garnished with oval leaves placed alternately, standing upon foot-stalks near one inch long; these have three longitudinal veins, and are of a pale green. The flowers come out at the wings of the stalk in clusters, almost the length of the young branches; they are of a greenish yellow colour, and appear in June, and are succeeded by broad, roundish, buckler-shaped seed-vessels, which have borders like the brims of a hat, the foot-stalks being fastened to the middle; these have three cells, each containing one seed.

This is by many persons supposed to be the plant, from which the crown of thorns which was put upon the head of our Saviour, was composed; the truth of which is supported by many travellers of credit, who affirm that this is one of the most common shrubs in the country of Judæa; and from the pliability of its branches, which may easily be wrought into any figure, it may afford a probability.

This shrub grows wild in most parts of the Levant, as also in Italy, Spain, Portugal, and the south of France, especially near Montpellier, from whence their seeds may be procured, for they do not ripen in England. These seeds should be sown as soon as possible after they arrive, on a bed of light earth, and the plants will come up the following spring; but when the seeds are kept out of the ground till spring, they will not come up till the next year, and very often fail; therefore it is much the best way to sow them in the autumn. These seedling plants may be transplanted the following season into a nursery to get strength, before they are planted out for good.

P A L

It may also be propagated by laying down its tender branches in the spring of the year, which if carefully supplied with water in dry weather, will take root in a year's time, and may then be taken off from the old plant, and transplanted where they are to remain.

The best time for transplanting this plant is in autumn, soon after the leaves decay, or the beginning of April, just before it begins to shoot, observing to lay some mulch upon the ground about their roots to prevent them from drying, as also to refresh them now and then with a little water until they have taken fresh root, after which they will require but very little care. They are very hardy, and will grow to be ten or twelve feet high, if planted in a dry soil and a warm situation. There is little beauty in this plant, but it is kept in gardens as a curiosity.

P A L M A. Plum. Gen. 1. Raii Meth. Plant. 135. The Palm-tree.

The CHARACTERS are,

It hath male and female flowers in some species on the same plant, and in others on different plants; the empalement of the male flowers are divided into three parts. The flowers of some species have three petals, and six stamens terminated by oblong summits, with an obsolete germen, supporting three short styles, crowned by acute stigmas; these are barren. The female flowers have a common sheath, but no empalement; they have six short petals, and an oval germen sitting upon an awl-shaped style, crowned by a trifid stigma. The germen afterward becomes a fruit of various forms and sizes in different species.

Mr. Ray ranges this genus in the front of his trees and shrubs, which have male flowers at remote distances from the fruit, sometimes on the same, and at others on different trees. Dr. Linnæus has separated the species under the following genera, Chamærops, Borassus, Corypha, Cocos, Phoenix, Areca, and Elate, ranging them in his Appendix.

The SPECIES are,

1. PALMA (*Dactylifera*) frondibus pinnatis, foliolis angustioribus aculeis terminalibus. *Palm-tree with winged leaves, whose lobes are narrow, terminated by spines.* Palma major. C. B. P. 506. *The greater Palm or Date-tree.*
2. PALMA (*Cocos*) frondibus pinnatis, foliolis replicatis, spadicibus alaribus, fructu maximo anguloso. *Palm-tree with winged leaves, whose lobes are folded back, foot-stalks proceeding from the sides of the branches, and a large angular fruit.* Palma Indica, coccifera, angulosa. C. B. P. 502. *Indian Palm-tree having an angular fruit, commonly called Cocoa-nut.*
3. PALMA (*Spinosa*) frondibus pinnatis, ubique aculeatis, aculeis nigricantibus fructu majore. *Palm-tree with winged leaves, which are every where armed with black spines, and bearing a larger fruit.* Palma tota spinosa major, fructu pruniformi. Sloan. Cat. Jam. 177. *Greater Palm-tree which is all over prickly, and a Plum-shaped fruit, commonly called great Macaw-tree.*
4. PALMA (*Altissima*) frondibus pinnatis, caudice æquali, fructu minore. *Palm-tree with winged leaves, an equal trunk, and a smaller fruit.* Palma altissima non spinosa, fructu pruniformi minore racemoso sparso. Sloan. Cat. Jam. 176. *The tallest Palm-tree having no spines, and a smaller Plum-shaped fruit, growing in long bunches scatteringly, commonly called the Cabbage-tree.*
5. PALMA (*Gracili*) frondibus pinnatis, caudice tereti aculeato, fructu minore. *Palm-tree with winged leaves, a taper prickly stalk, and a smaller fruit.* Palma spinosa minor, caudice gracili, fructu pruniformi, minimo rubro. Sloan. Cat. Jam. 178. *Smaller prickly Palm-tree with a slender stalk, and the least, red, Plum-shaped fruit, called Prickly Pole.*
6. PALMA (*Oleosa*) frondibus pinnatis, foliolis linearibus planis, stipitibus spinosis. *Palm-tree with winged leaves, having narrow plain lobes, and prickly midribs.* Palma foliorum pediculis spinosis, fructu pruniformi luteo oleoso. Sloan. Cat. Jam. 175. *Palm-tree with*

P A L

prickly foot-stalks to the leaves, and a yellow, Plum-shaped, oily fruit, commonly called oily Palm-tree.

7. PALMA (*Prunifera*) frondibus pinnato-palmatis plicatis, caudice squamato. *Palm-tree with hand-shaped winged leaves which are plaited, and a scaly stalk.* Palma Brasiliensis prunifera, folio plicatili seu flabeliformi, caudici squamato. Raii Hist. 1368. *Plum-bearing Palm-tree of the Brasils, with a plaited or fan-shaped leaf, and a scaly stalk, called Palmetto or Thatch.*
8. PALMA (*Polypodifolia*) frondibus pinnatis, foliolis linearilanceolatis, petiolis spinosis. Hort. Cliff. 482. *Palm-tree with winged leaves, whose lobes are linearly spear-shaped, and prickly foot-stalks.* Palma Japonica, spinosis pediculis, polypodii folio. Boerh. Ind. alt. 2. 170. *Palm-tree of Japan with prickly foot-stalks, and a Polypody leaf, or the Sago-tree.*
9. PALMA (*Pumila*) fructu clavato polypyreno. Trew. Dec. tab. 26. *Palm-tree with a club-shaped fruit containing many seeds.* Palma Americana foliis polygonati brevioribus, leviter serratis, & nonnihil spinosis, trunco crasso. Pluk. Phyt. tab. 103. fig. 2. & tab. 309. fig. 5. *American Palm-tree, with shorter Solomon's Seal leaves which are lightly sawed and somewhat prickly, with a thick trunk.*
10. PALMA (*Americana*) frondibus pinnatis, foliolis lanceolatis plicatis geminatis sparsis. *Palm-tree with winged leaves, whose lobes are spear-shaped, plaited, and come out by pairs from one point, standing thinly along the midrib.* Palma altissima, non spinosa, fructu oblongo. Houst. MSS. *Tallest Palm-tree having no prickles, and bearing an oblong fruit.*
11. PALMA (*Draco*) foliis simplicibus ensiformibus integerrimis flaccidis. *Palm-tree with single, sword-shaped, entire flaccid leaves.* Palma prunifera foliis yuccæ, fructu in racemis congestis cerasi formi, duro, cinereo, pisi magnitudine, cujus lacryma sanguis draconis est dicta. Com. Cat. Amst. *Plum-bearing Palm-tree, with leaves like those of the Yucca, and fruit gathered in long bunches, which are Cherry-shaped, Ash-coloured, hard, and the size of Peas, whose tears are called Dragons Blood, commonly called Dragon-tree.*

The first sort here mentioned is the common Date-tree, which grows plentifully in Africa, and some of the eastern countries, from whence the fruit is brought to England. This rises to a great height in the warm countries; the stalks are generally full of rugged knots, which are the vestiges of the decayed leaves, for the trunks of these trees are not solid like other trees, but the center is filled with pith, round which is a tough bark full of strong fibres while young, but as the trees grow old, so this bark hardens and becomes ligneous; to this bark the leaves are closely joined, which in the center rise erect, being closely folded or plaited together, but after they are advanced above the vagina which surrounds them, they expand very wide on every side the stem, and, as the older leaves decay, the stalk advances in height. The leaves of these trees, when grown to a size for bearing fruit, are six or eight feet long, and may be termed branches; (for the trees have no other) these have narrow long leaves (or pinnæ) set on alternately their whole length. The small leaves or lobes are toward the base three feet long, and little more than one inch broad; they are closely folded together when they first appear, and are wrapped round by brown fibres or threads, which fall off as the leaves advance, making way for them to expand; these never open flat, but are hollow like the keel of a boat, with a sharp ridge on their backside; they are very stiff, and, when young, of a bright green, ending with a sharp black spine. These trees have male flowers on different plants from those which produce the fruit, and there is a necessity for some of the male trees to grow near the female trees to render them fruitful; or, at least, to impregnate the ovary of the seed, without which the stones, which are taken out of the fruit, will not grow. Most of the old authors, who have mentioned these trees, affirm, that unless the female or fruit-bearing Palm-trees have the assistance

of the male, they are barren; therefore in such places where there are no male trees near the female, the inhabitants cut off the bunches of male flowers when they are just opened, and carry them to the female trees, placing them on the branches near the female flowers to impregnate them; which, they all agree, has the desired effect, rendering the trees fruitful, which would otherwise have been barren. Pere Labat in his account of America, mentions a single tree of this kind, growing near a convent in the island of Martinico, which produced a great quantity of fruit, which came to maturity enough for eating; but, as there was no other tree of this kind in the island they were desirous to propagate it, and accordingly planted great numbers of the stones for several years, but not one of them grew; therefore after having made several trials without success, they were obliged to send to Africa, where these plants grew in plenty, for some of the fruit; the stones of which they planted, and raised many of the plants. He then conjectures, that the single tree before-mentioned, might be probably so far impregnated by some neighbouring Palm-trees of other species, as to render it capable of ripening the fruit, but not sufficient to make the seeds prolific, as is the case when animals of different kinds copulate.

The flowers of both sexes come out in very long bunches from the trunk between the leaves, and are covered with a spatha, (or sheath) which opens and withers; those of the male have six short stamina, with narrow four-cornered summits filled with farina. The female flowers have no stamina, but have a roundish germen, which afterward becomes an oval berry, with a thick pulp inclosing a hard oblong stone, with a deep furrow running longitudinally. The bunches of fruit are sometimes very large.

This species of Palm is by Dr. Linnæus titled *Phoenix*, which is the Greek name of it, and he makes it a distinct genus. There are some varieties, if not different species of this tree, in the warm countries; but as we cannot expect to see the trees in perfection in our country, it is not likely we shall come to any certainty how they differ from each other.

These plants may be easily produced from the seeds taken out of the fruit, (provided they are fresh) which should be sown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, which should be kept in a moderate temperature of heat, and the earth frequently refreshed with water.

When the plants are come up, they should be each planted into a separate small pot filled with the same light rich earth, and plunged into a hot-bed again, observing to refresh them with water, as also to let them have air in proportion to the warmth of the season, and the bed in which they are placed. During the summer time they should remain in the same hot-bed, but in the beginning of August you should let them have a great share of air to harden them against the approach of winter; for if they are too much forced, they will be so tender as not to be preserved through the winter without much difficulty, especially if you have not the conveniency of a bark-stove to keep them in.

The beginning of October you must remove the plants into the stove, placing them where they may have a moderate share of heat (these being somewhat tenderer, while young, than after they have acquired some strength;) though indeed they may be sometimes preserved alive in a cooler situation, yet their progress would be so much retarded, as not to recover their vigour the succeeding summer. Nor is it worth the trouble of raising these plants from seeds, where a person has not the conveniency of a stove to forward their growth; for where this is wanting, they will not grow to any tolerable size in twenty years.

Whenever these plants are removed, (which should be done once a year) you must be very careful not to cut or injure their large roots, which is very hurtful to them; but you should clear off all the small fibres

which are inclinable to mouldiness, for if these are left on, they will in time decay, and hinder the fresh fibres from coming out, which will greatly retard the growth of the plants.

The soil in which these plants should be placed, must be composed in the following manner, viz. half of light fresh earth taken from a pasture ground, the other half sea-sand, and rotten dung or tanners bark, in equal proportion; these should be carefully mixed, and laid in a heap three or four months at least before it is used, but should be often turned over to prevent the growth of weeds and to sweeten the earth.

You should also observe to allow them pots proportionable to the sizes of the plants; but you must never let them be too large, which is of worse consequence than if they are too small. During the summer season they should be frequently refreshed with water, but you must be careful not to give it in too great quantities; and in winter they must be now and then refreshed, especially if they are placed in a warm stove, otherwise they will require very little water at that season.

These plants are very slow growers, even in their native countries, notwithstanding they arrive to a great magnitude; for it has been often observed by several of the old inhabitants of those countries, that the plants of some of these kinds have not advanced two feet in height in ten years; so that when they are brought into these countries, it cannot be expected they should advance very fast, especially where there is not due care taken to preserve them warm in winter. But however slow of growth these plants are in their native countries, yet they may be with us greatly forwarded, by placing the pots into a hot-bed of tanners bark, which should be renewed as often as is necessary, and the plants always preserved therein both winter and summer, observing to shift them into larger pots as they advance in growth, as also to supply them with water properly, with which management I have had several of them come on very fast; for I observe the roots of these plants are very apt to root into the bark, if their pots remain a considerable time without shifting, where they meet with a gentle warmth, and the moisture arising from the fermentation of the bark doth preserve their fibres plump and vigorous; but although the leaves grow tall in a few years with this management, yet it is long before the plants come to have any stems. There are plants now in the Chelsea Garden, whose leaves are seven feet long, which were raised from seeds more than twenty years ago, and their stems are not two feet high, some of which have produced small bunches of male flowers.

The second sort here mentioned, is the *Cocoa-nut*, whose fruit are frequently brought to England, some of which are of a large size. The branches of this tree are winged like those of the former, but the small leaves or lobes are three times as broad; they open flat, their borders fold backward, and are of a lighter green than those of the first sort. The whole leaf (or branch) is often twelve or fourteen feet long; the male flowers grow in different parts of the same tree with the fruit, proceeding from the trunk between the leaves; they are disposed in long bunches, as are also the female, the nuts growing in very large clusters, which are covered with a thick fibrous coat adhering closely to them. The nuts are large, oval, and have three holes in the shell at the top; the kernel is firm, white within, and the shell contains a quantity of pale juice, which is called the milk.

The *Cocoa-nut* is cultivated in most of the inhabited parts of the East and West-Indies, but is supposed a native of the Maldives, and the desert islands of the East-Indies, from whence it is supposed it hath been transported to all the warm parts of America; for it is not found in any of the inland parts, nor any where far distant from settlements. It is one of the most useful trees to the inhabitants of America, who have many of the common necessities of life from it. The bark of the tree is made into cordage, the shell of the

nut into drinking bowls, the kernel of the nut affords them a wholesome food, and the milk contained in the shell a cooling liquor. The leaves of the trees are used for thatching their houses, and are also wrought into baskets, and most other things which are made of Osiers in Europe.

This tree is propagated by planting of the nuts, which in six weeks or two months after planting will come up, provided they are fresh and thoroughly ripe, which is what few of them are which are brought to England; for they always gather them before they are ripe, that they may keep during their passage; so that the best way to bring nuts into England for planting, would be to take such of them as are fully ripe, and put them in dry sand in a tub, where the vermin may not come to them; and these will often sprout in their passage, which will be an advantage, because then they may be immediately planted into pots of earth, and plunged into the bark-bed.

These plants, in the hot islands of America, make considerable progress in their growth, in which places there are some trees of very great magnitude; but in Europe it is of much slower growth, being many years before it advances to any considerable height; but as the young leaves of this plant are pretty large, they make a good appearance amongst other tender exotic plants in two or three years time. This plant is preserved in some curious gardens in England for variety, where it must be placed in the bark-love, and managed as hath been directed for the other kind of Palm; observing, as often as they are transplanted, not to cut their strong roots, which is generally death to most of the Palm kind. These plants must not be too much confined in their roots, for if they are, they will make but little progress; therefore, when the young plants have filled the pots with their roots, they should be shifted into tubs of a moderate size, that their roots may have room to extend; but these tubs must be kept constantly plunged into the bark-bed, otherwise the plants will not thrive. The method of raising these plants from the nuts, when they are planted before they have sprouted, is fully described under the article of raising exotic seeds; to which the reader is desired to turn, to avoid repetition. The third sort is commonly called Macaw-tree by the inhabitants of the British Islands in America; this rises to the height of thirty or forty feet. The stem is generally larger toward the top than at bottom; the branches (or rather the leaves) are winged; the small leaves or lobes are long and very broad; the stalk and leaves are strongly armed with black spines of various sizes in every part; the male and female flowers are on the same tree, coming out in the same manner as the Cocoa-nut. The fruit is about the size of a middling Apple, and is inclosed in a very hard shell.

The Macaw-tree is very common in the Caribbee Islands, where the negroes pierce the tender fruit, from whence flows out a pleasant liquor, of which they are very fond; and the body of the tree affords a solid timber, with which they make javelins, arrows, &c. and is by some supposed to be a sort of Ebony. This tree grows very slow, and requires to be kept warm in winter.

The fourth sort is commonly called Cabbage-tree in the West-Indies; this rises to a very great height in the countries where it grows naturally. Ligon in his History of Barbadoes says, there were then some of these growing there, which were more than two hundred feet high, and that he was informed they were a hundred years growing to maturity, so as to produce seeds. The stalks of these trees are seldom larger than a man's thigh; they are smoother than those of most other sorts, for the leaves naturally fall off entire from them, and only leave the vestigia or marks where they have grown. These leaves (or branches) are twelve or fourteen feet long; the small leaves or lobes are about a foot long, and half an inch broad, with several longitudinal plaits or furrows ending in soft acute points; these are not so stiff as those

of the first sort, and are placed alternately. The flowers come out in long loose bunches below the leaves; these branch out into many loose strings, and are near four feet long, upon which the flowers are thinly placed. The female flowers are succeeded by fruit about the size of a Hazel nut, having a yellowish skin, sitting close to the strings of the principal foot-stalk.

As the inner leaves of this encompass the future buds more remarkably than most of the other species, so it is distinguished by this appellation of Cabbage-tree; for the center shoots, before they are exposed to the air, are white and very tender, like most other plants which are blanched; and this is the part which is cut out and eaten by the inhabitants, and is frequently pickled and sent to England by the title of Cabbage; but whenever these shoots are cut out, the plants decay, and never after thrive; so that it destroys the plants, which is the reason that few of the trees are now to be found in any of the islands near settlements, and those are left for ornament.

The fifth sort is commonly called Prickly Pole in Jamaica, where it naturally grows. These trees are commonly found in thickets, where a great number of them are close together. Their stalks are slender, seldom more than five or six inches diameter, but rise to the height of forty feet, and are closely armed with long thorns. The leaves are placed circularly on the top, (as in most of the species.) These are winged, but the lobes are shorter and greener than those of the other sorts, and are closely armed with thorns. The flowers come out in the same manner as those of the Cocoa-nut, upon long branching foot-stalks; they are larger than the largest gray Peas, flattened at the top, and are covered with a red skin. The inhabitants of Jamaica make rammers and rods for scowering of guns, of the stems of these trees, which are very tough and pliable; but there is no use made of any other part, so far as I can learn.

The sixth sort is called in the West-Indies the Oily Palm, and by some Negroes Oil, for the fruit of this tree was first carried from Africa to America by the negroes. It grows in great plenty on the coast of Guinea, and also in the Cape de Verd Islands, but was not in any of our American colonies till it was carried there; but now the trees are in plenty in most of the islands, where the negroes are careful to propagate them.

The branches, (or rather the leaves) of this tree, are winged; the small leaves or lobes, are long, narrow, and not so stiff as most of the other sorts; the foot-stalks of the leaves are broad at their base, where they embrace the stem, diminishing gradually upward, and are armed with strong, blunt, yellowish thorns, which are largest at their base. The flowers come out at the top of the stem between the leaves; some bunches have only male flowers, others have female; the latter are succeeded by oval berries, bigger than those of the largest Spanish Olives, but of the same shape; these grow in very large bunches, and when ripe are of a yellowish colour.

From the fruit the inhabitants draw an oil, in the same way as the oil is drawn from Olives; from the body of the tree they extract a liquor, which, when fermented, has a vinous quality, and will inebriate. The leaves of the tree are wrought into mats by the negroes, on which they lie.

The seventh sort is called Palmetto-tree, or Thatch, by the inhabitants of Jamaica, where this tree grows upon all the honey-comb rocks in great plenty. It rises with a slender stalk ten or twelve feet high, which is naked and smooth, and at the top garnished with many fan-shaped leaves placed circularly; these have foot-stalks two or three feet long, which are armed with a few strong, green, crooked spines; the pinnæ, or lobes, do all meet in one center, where they join the foot-stalk, and are joined together a third part of their length from their base; they are at first closely folded into plaits, but afterward spread out like a fan; their ends being pliant often hang downward,

downward, and between these pinnæ hang down long threads. The flowers and fruit come out from between the leaves; the fruit is of the shape and size of the small Lucca Olives. The leaves of this tree are used for thatch all over the West-Indies.

The eighth sort grows naturally in Japan, and also upon rocky dry mountains at Malabar. This in time rises with a strait trunk about forty feet high, which has many circles round it the whole length, which are occasioned by the vestigia of the leaves, which are placed circularly round the stem; so as these separate entirely and fall off, the circles remain where their base embraced the stalk. The stalks are terminated by an obtuse cone, just below which the leaves are placed; these on the large trees are eight or nine feet long, but those of the small plants are much less; the largest I have seen were not more than two feet long. The base of the foot-stalk, which partly embraces the trunk, is broad and three-cornered, and is armed on each side with short spines to the place where the lobes, or small leaves, begin. These pinnæ or lobes, are long, narrow, and entire, of a lucid green on their upper side, standing by pairs opposite along the midrib, very close together. The flowers and fruit are produced in large bunches at the foot-stalks of the leaves; the fruit is oval, about the size of a large Plum, and nearly of the same shape; the skin, or covering, changes first yellow, and afterward red when ripe, of a sweet taste, under which is a hard brown shell, inclosing a white nut, which is in taste like the Chestnut.

From the pith of the trunk of this tree is made the sago; this is first pulverized, then it is made into a paste, and afterward granulated.

The ninth sort was discovered by the late Dr. Houstoun, growing naturally in the sands near Old Vera Cruz in America. This hath a thick stem, which seldom rises more than two feet high. The leaves come out round the upper part of the stem, standing upon foot-stalks which are a foot and a half long; they are winged; the lobes or small leaves are about five inches long, and one and a half broad in the middle, drawing to a point at both ends; they are stiff, smooth, and entire, having a few small indentures at their points, and are placed alternate, of a pale green colour; there are fourteen or fifteen of these lobes ranged along the midrib, or stalk. The fruit rises up from the side of the stem, upon a short thick foot-stalk, standing upright, and shaped like a club, having many red seeds about the size of large Peas, standing in separate cells round the central foot-stalk, to which they adhere. These plants have their male flowers on separate plants from the fruit, for all those plants which have flowered in England are of the male kind. These plants lose their leaves before the fruit is ripe annually. The first time when Dr. Houstoun saw these plants growing at La Vera Cruz, they were in full leaf, but on his return to the same place three months after, the fruit was then ripe, and all the leaves were fallen off; and this he afterwards observed the following season.

The tenth sort was discovered by the late Dr. Houstoun in the Spanish West-Indies. This rises with a very tall naked trunk, garnished at the top with long winged branches or leaves, whose lobes are spear-shaped and plaited; they are of a softer texture than any of the other sorts, and for the most part come out two from the same point, so stand by pairs on the same side of the midrib; they have two lobes on a side a little above each other, but there is a great space between every four lobes. The flowers come out in long bunches from between the leaves, the male flowers hanging on long tender strings; but the fruit, which is about the size of a middling Plum, is collected into large bunches.

The eleventh sort grows naturally in the Cape Verd Islands, from whence I had one of the plants brought me, as also in the Madeira, from whence I have received the seeds. This is called Dragon-tree, because the inspissated juice of the plants becomes a

red powder, very like the eastern Dragons Blood, and is frequently used instead of it in the shops; but the tree, from whence the true Dragons Blood is taken, is of a very different genus from this. Dr. Van Royen, in the Prodomus of the Leyden Garden, has ranged this among the Yuccas, I suppose, from the similitude of the plant to those of that genus; for, as the fruit of this is a berry not unlike those of the Bay-tree, and the seeds of the Yucca grow in capsules with three cells, they cannot be of the same genus; nor have we any good account of the real characters of this plant, so as absolutely to determine the genus. Dr. Linnæus has, upon the information of his pupil Læfing, ranged it in his genus of Aiparagus, to which it seems to have little affinity; therefore, as it has by several modern authors been ranged under this title, I have continued it there. This rises with a thick trunk nearly equal in size the whole length, the inner part of which is pithy; next to this is a circle of strong fibres, and the outside is soft. The stalk or trunk rises twelve or fourteen feet high, and is nearly of the same diameter the whole length, which is rarely more than eight or ten inches; there are the circular marks or rings left the whole length, where the leaves are fallen off; for as these half embrace the stalk with their base, so when they fall away, the vestigia where they grew remain. The top of the stalk sustains a large head of leaves, which come out singly all round it; they are shaped like those of the common Iris, but are much longer, being often four or five feet long, and an inch and a half broad at their base, where they embrace the stalk, and lessen gradually to the end, where they terminate in a point. These leaves are pliable, and hang down all round the stem; they are entire, and of a deep green, smooth on both surfaces, and greatly resemble those of the common yellow Iris. As this plant has not flowered in England, I can give no account of its flowers; but so far as I can judge from the berries which I have received, it may properly enough be ranged in this genus.

All these sorts of Palms are propagated by seeds, which should be sown in the same way as hath been directed for the first sort, and the plants should afterward be treated in the same manner; with this difference, that such of them as are natives of very warm countries, will require to be kept in a warmer air. The second, third, fourth, fifth, sixth, seventh, eighth, and ninth sorts should be constantly kept in the bark-bed in the stove, otherwise they will not make great progress in England; and when they do thrive, they grow in about twenty years too tall for most of the stoves which are at present built here, nor can we hope to see many of them produce their fruit in England; so the plants are preserved by the curious for their foliage, which being so singular and different from that of the European trees, renders them worthy of care.

The other sorts may be kept in a dry stove in winter in a moderate temperature of air, and in the heat of summer they may be exposed to the open air in a warm sheltered situation for about three months, but they should be removed into the stove before the morning frosts come on in the autumn. When these plants are kept in a moderate degree of warmth, they should have but little water during the winter season; and in the summer, when they are exposed in the open air, they must not be often watered, unless the season is remarkably dry and warm, for too much moisture will soon destroy them. The other management of them is nearly the same as for the Date Palms, which is not to cut their principal roots when they are shifted from one pot to another, nor to confine their roots too much; but as the plants grow in size, they should annually be removed into pots a size larger than those they were in the former year. The earth in which they are planted, should be light, so as to let the moisture easily pass off; for if it is strong, and detains the moisture, the tender fibres of the roots will rot.

PANAX. Lin. Gen. Plant. 1031. Panacea. Mitch. Gen. 26. Araliastrum. Vaill. 6. Ginseng or Ninseng.

The CHARACTERS are,

It hath male and hermaphrodite flowers on distinct plants; the male have simple globular umbels, composed of several coloured rays which are equal. The involucre on the outside, consists of the same number of small spear-shaped leaves. The flower has five narrow, oblong, blunt petals, which are reflexed, sitting on the empalement, and five oblong slender stamina inserted in the empalement, terminated by single summits. The hermaphrodite umbels are simple, equal, and clustered; the involucre is small, permanent, and composed of several awl-shaped leaves; the empalement is small and permanent. The flowers have five oblong equal petals, which are recurved, and five short stamina terminated by single summits which fall off, with a roundish germen under the empalement, supporting two small erect styles, crowned by single stigmas. The germen afterward becomes an umbilicated berry with two cells, each containing a single, heart-shaped, convex, plain seed.

This genus of plants is ranged in the second section of Linnæus's twenty-third class, which includes the plants whose male flowers are upon distinct plants from the female or hermaphrodite flowers.

The SPECIES are,

1. **PANAX** (*Quinquefolium*) foliis ternis quinatis. Flor. Virg. 147. *Panax* with trifoliate Cinquefoil leaves. Araliastrum quinquefolii folio, majus, Ninsin vocatum. D. Sarrafin. Vaill. Gen. 43. *Greater five-leaved Bastard Aralia*, called Ninsin.
2. **PANAX** (*Trifolium*) foliis ternis ternatis. Flor. Virg. 35. *Panax* with three trifoliate leaves. Araliastrum fragariæ folio minus. Vaill. Gen. 43. *Smaller Bastard Aralia* with a Strawberry leaf.

Both these plants grow naturally in North America; the first is generally believed to be the same as the Tartarian Ginseng, the figures and descriptions of that plant, which have been sent to Europe by the missionaries, agreeing perfectly with the American plant.

This hath a fleshy taper root as large as a man's finger, which is jointed, and frequently divided into two smaller fibres downward. The stalk rises near a foot and a half high, naked at the top, where it generally divides into three smaller foot-stalks, each sustaining a leaf composed of five spear-shaped lobes, which are sawed on their edges; they are of a pale green, and a little hairy. The flowers grow on a slender foot-stalk, just at the division of the foot-stalks, which sustain the leaves, and are formed into a small umbel at the top; they are of an herbaceous yellow colour, composed of five small petals which are recurved. These appear the beginning of June, and are succeeded by compressed heart-shaped berries, which are first green, but afterward turn red, inclosing two hard, compressed, heart-shaped seeds, which ripen the beginning of August.

The Chinese hold this plant in great esteem, according to the accounts which have been transmitted to Europe by the missionaries. Father Jartoux in his Letters says, that the most eminent physicians in China have written whole volumes upon the virtues of this plant, and make it an ingredient in almost all remedies which they give to their nobility, for it is of too high price for the common people. They affirm, that it is a sovereign remedy for all weakness occasioned by excessive fatigues either of body or mind; that it cures weakness of the lungs, and the pleurisy; that it stops vomitings; that it strengthens the stomach, and helps the appetite; that it strengthens the vital spirits, and increases lymph in the blood; in short, that it is good against dizziness of the head and dimness of sight, and that it prolongs life in old age.

This father also says, he has made trials of the root of this plant himself, and has, in an hour after taking half one of the roots, found himself greatly recovered from weariness and fatigue, and much more vigorous, and could bear labour with greater ease than before.

He likewise mentions the emperor's having employed ten thousand Tartars in the year 1709, to gather this plant in the deserts, where it naturally grows; these were attended by a guard of mandarines, who encamped with their tents in such places as are proper for the subsistence of their horses, and from time to time send their orders to the respective troops under their care; and when they have completed their collection of roots, they return with their cargo to the city. The roots of this plant which have been gathered in America and brought to England, have been sent to China; where, at the beginning, there was a good market for them; but the quantities which were afterward sent, did not answer so well; the market being overstocked with that commodity.

This plant has been introduced to the English gardens from America, and where it has been planted in a shady situation and a light soil, the plants have thriven and produced flowers, and ripened their seeds annually, but not one of these seeds have grown; for I have several years sown them soon after they were ripe, without any success; I have also sown of the seeds which were sent me from America several times in various situations, and have not raised a single plant from either; and by the accounts which the missionaries have sent from China, it appears, they have had no better success with the seeds of this plant, which they say they have frequently sown in the gardens in China, but could not raise one plant; so that I believe there is a necessity for the hermaphrodite plants to have some male plants stand near them, to render the seeds prolific; for all those plants which I have seen, or saved the seeds from, were such as had hermaphrodite flowers; and though the seeds seemed to ripen perfectly, yet their not growing, though I have waited three years without disturbing of the ground, confirms me in this opinion.

The second sort grows naturally in the same countries, but whether it is possessed of the same qualities as the first I cannot say; I have seen but one plant of this sort in England, which was sent me a few years ago from Maryland, and did not live over the first summer, which was remarkably dry, and being planted in a dry soil, was the occasion of its death; the stalk of this was single, and did not rise more than five inches high, dividing into three foot-stalks, each sustaining a trifoliate leaf, whose lobes were longer, narrower, and deeper indented on their edges, than those of the former. The flower-stalk rose from the divisions of the foot-stalk of the leaves, but before the flowers opened, the plant decayed, so I can give no farther account of it.

PANCRATIUM. Dill. Hort. Elth. 221. fol. 289. Lin. Gen. Plant. 365. Narcissus. Tourn. Inst. R. H. 353. tab. 185. Sea Daffodil.

The CHARACTERS are,

The flowers are inclosed in an oblong spathe or sheath, which tears open on the side and withers. The flowers have a funnel-shaped cylindrical nectarium of one leaf, spreading open at the top, and six spear-shaped petals, which are inserted on the outside of the nectarium above its base, with six long stamina inserted in the brim of the nectarium, terminated by oblong prostrate summits. They have a three-cornered obtuse germen situated under the flower, supporting a long slender style, crowned by an obtuse stigma. The germen afterward becomes a roundish three-cornered capsule with three cells, filled with globular seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, which includes those plants whose flowers have six stamina and one style.

The SPECIES are,

1. **PANCRATIUM** (*Maritimum*) spathâ multiflorâ, petalis planis, foliis lingulatis. Lin. Sp. Plant. 291. *Pancratium* with a sheath containing many flowers, having plain petals, and tongue-shaped leaves. Narcissus maritimus. C. B. P. 540. *The Sea Daffodil.*
2. **PANCRATIUM** (*Illyricum*) spathâ multiflorâ, foliis ensiformibus, staminibus nectario longioribus. Flor. Leyd. Prod. 34. *Pancratium* with many flowers in a

sheath, sword-shaped leaves, and stamina longer than the nectarium. Narcissus Illyricus liliaceus. C. B. P. 55. *Lily Daffodil of Slavonia.*

3. PANCRATIUM (Zeylanicum) spathâ uniflorâ, petalis reflexis. Flor. Zeyl. 126. *Pancratium with one flower in a sheath, whose petals are reflexed.* Narcissus Zeylanicus, flore albo hexagono odorato. H. L. 691. *Daffodil of Ceylon, with a white hexagonal sweet flower.*
4. PANCRATIUM (Carribæum) spathâ biflorâ. Hort. Cliff. 133. *Pancratium with two flowers in a sheath.* Pancratium Mexicanum, flore gemello candido. Hort. Elth. 299. tab. 222. *Mexican Pancratium, with two white flowers.*
5. PANCRATIUM (Amboinense) spathâ multiflorâ, foliis ovatis nervosis. Lin. Sp. Plant. 291. *Pancratium with many flowers in a sheath, and oval veined leaves.* Narcissus Amboinensis, folio latissimo subrotundo. Hort. Amst. 1. p. 77. tab. 39. *Narcissus of Amboyna, with the broadest roundish leaf.*

PANCRATIUM (Americanum) spathâ multiflorâ, foliis carinatis angustioribus. *Pancratium with many flowers in a sheath, and narrow keel-shaped leaves.* Narcissus Americanus, flore multiplici, albo, odore balsami Peruviani. Tourn. Inst. R. H. 358. *American Narcissus with many white flowers, smelling like Balsam of Peru.*
8. PANCRATIUM (Latifolium) spathâ multiflorâ, foliis carinatis latioribus. *Pancratium with many flowers in a sheath, and broader keel-shaped leaves.* Narcissus totus albus, latifolius, polianthos, major odoratus, staminibus sex è tubi ampli margine extantibus. Sloan. Cat. Jam. 115. *Broad-leaved Daffodil, with many larger sweet flowers which are very white, and a large tube, out of whose border proceed six stamina.*

The first sort grows naturally on the sea-coast in Spain, and the south of France. This hath a large, coated, bulbous root, of an oblong form, covered with a dark skin; the leaves are shaped like a tongue; they are more than a foot long, and one inch broad, of a deep green, six or seven of them rising together from the same root, encompassed at bottom with a vagina or sheath; between these arise the stalk, which is a foot and a half long, naked, sustaining at the top six or eight white flowers, inclosed in a sheath, which withers and opens on the side, to make way for the flowers to come out. The germen are situated close to the top of the stalk, from these arise the tube of the flowers, which are three inches long; they are very narrow, swelling at the top, where the cup or nectarium is situated, on the outside of which is fastened the six segments or petals of the flower; these are narrow, and extend a great length beyond the nectarium; from the border of the nectarium arise six long slender stamina, terminated by oblong summits which are prostrate, and in the center arises a style the length of the stamina, terminated by an obtuse stigma. The flowers of this sort do not appear in England till the latter end of August, so are not succeeded by seeds here. The leaves of this sort are green all the winter, and decay in the spring, so the roots should be transplanted in June, after the leaves are decayed. This must be planted in a very warm border, and screened from severe frost, otherwise it will not live through the winter in England.

The second sort grows naturally in Slavonia, and also in Sicily; this hath a large, coated, bulbous root, covered with a dark skin, sending out many thick strong fibres, which strike deep in the ground; the leaves are sword-shaped, a foot and a half long and two inches broad, of a grayish colour. The stalks are thick, succulent, and rise near two feet high, sustaining at the top six or seven white flowers shaped like those of the first sort, but the tube is shorter and the stamina are much longer. This

flowers in June, and frequently produces seeds which ripen in September.

This sort is hardy, and will live through the winter in the full ground, being never injured but in very severe winters; and if, in such seasons, the surface of the ground is covered with tanners bark, sea-coal ashes, straw, or Peas-haulm, to keep out the frost, there will be no danger of the roots suffering. It is propagated either by offsets from the roots, or from seeds; the former is the more expeditious method, for the offsets will flower very strong the second year; whereas those which are raised from seeds, seldom flower in less than five years.

The roots of this plant should not be removed oftener than every third year, if they are expected to flower strong; the best time to transplant them is in the beginning of October, soon after their leaves decay: they should not be kept long out of the ground, for as they do not lose their fibres every year, so if these are dried by long keeping out of the ground, it greatly weakens the roots. It loves a light sandy soil, and a sheltered situation; the roots should be planted nine inches or a foot asunder every way, and five inches deep in the ground.

If the plants are propagated by seeds, they should be sown in pots filled with light earth soon after they are ripe; these pots should be placed under a hot-bed frame in winter to screen them from frost, but the glasses must be taken off every day in mild weather. The other management being the same as for the Narcissus, I need not repeat it here; so shall only mention, that the young roots will require a little protection in winter, till they have obtained strength.

The third sort grows naturally at Ceylon; this hath a pretty large bulbous root, the leaves are long and narrow, of a grayish colour, and pretty thick, standing upright; the stalk rises between them a foot and a half high, naked, sustaining one flower at the top, whose petals are reflexed backward; the nectarium is large, and cut at the brim into many acute segments; the stamina are long, and turn toward each other at their points, in which it differs from the other species. The flower has a very agreeable scent, but is of short duration; this is very rare in the gardens at present.

The fourth sort grows naturally at La Vera Cruz, from whence the late Dr. Houstoun brought some of the roots. The leaves of this sort are about a foot long and two inches broad, having three longitudinal furrows. The stalk rises about a foot high, then divides like a fork into two small foot-stalks, or rather tubes, which are narrow, green, and at first are encompassed by a thin spatha (or sheath) which withers, and opens to give way to the flowers, which are white, and shaped like those of the other species, but have no scent.

The fifth sort grows naturally at Amboyna, and also in the American islands. The root of this sort is oblong, white, and sends out several thick fleshy fibres, which strike downward; the leaves stand upon very long foot-stalks, some of them are oval, and others heart-shaped, about seven inches long, and five broad, ending in points, having many deep longitudinal furrows; they are of a light green, and their borders turn inward. The stalk is thick, round, and succulent, rising near two feet high, sustaining at the top several white flowers, shaped like the other species, but the petals are broader, the tube is shorter, and the stamina are not so long as the petals. These flowers have a thin sheath or covering, which splits open longitudinally, to make way for the flowers.

The sixth sort grows naturally in moist boggy soils in Georgia, where Mr. Catesby discovered it. This hath a roundish bulbous root, covered with a light brown skin, from which arise several narrow dark green leaves, about a foot long; between these come out a thick stalk about nine inches high, sustaining six or seven white flowers, with very narrow petals, having large bell-shaped nectariums or cups, which are deeply indented on their brims; the stamina do not rise far above

above the nectarium, and are terminated by yellow summits.

The seventh sort grows naturally in the islands of the West-Indies, where it is called white Lily. This hath a pretty large bulbous root, a little flatted at the top, covered with a brown skin; the leaves are near a foot and a half long, and little more than one inch broad, of a dark green, and hollowed in the middle like the keel of a boat. The stalks rise near two feet high, which are thick, succulent, and naked, sustaining at the top eight or ten white flowers, shaped like those of the first sort, but are of a purer white, and have a strong sweet odour, like that of Balsam of Peru. The stamina of this are very long, spreading out wide each way; the pointal is of the same length, standing in the middle of the nectarium. These flowers are of short duration, seldom continuing longer in beauty than three or four days, and in very hot weather not so long; when these fade, the germen, which are situated at the bottom of the tubes, turn to so many oblong bulbs, which are irregular in form, and when ripe, drop off in the ground, where they put out fibres and become plants.

These foreign species are most, if not all of them, of this kind, bearing bulbs; whereas the two first have seed-vessels with three cells, inclosing many roundish black seeds, so that though they agree in the characters of their flowers, yet in this particular they differ greatly.

The eighth sort grows naturally in the West-Indies, where it is not distinguished from the former; but as I have frequently propagated both by their bulbs which succeed the flowers, and have always found the plants so raised continue their difference, I make no doubt of their being distinct species. This differs from the former, in the leaves being much longer and broader than that; for these are near two feet long, and more than three inches broad, and are hollowed like the keel of a boat. The flowers are larger, the petals longer, and the scent is not so strong as that of the former, and the roots flower in every season of the year. This seems to be the sort figured by Dr. Trew, in the twenty-seventh table of his Decades of Rare Plants, but if it is, the leaves in his figure are too flat.

These six sorts last mentioned are tender, so will not thrive in England, unless they are placed in a warm stove. The best way to have these plants in perfection, is to plunge the pots into the bark-bed in the stove, where they will thrive and flower exceeding well; for though they may be preserved in a dry stove, yet those will not thrive so well, nor will their flowers be so strong, as when they are plunged in the tan-bed, nor will they flower oftener than once a year; whereas when they are in the tan-bed, the same roots will often flower two or three times in a year. I have had several of the species in flower at all seasons of the year, so there has not been a month when some of them were not in flower.

They are propagated by offsets from the roots, as also by the bulbs which succeed the flowers; if the latter are planted in small pots filled with light earth from a kitchen-garden, and plunged into a moderate hot-bed, they will soon put out roots and leaves, and with proper management, will become blowing roots in one year, so that they may be easily propagated; and if they are constantly kept in the tan-bed in the stove, they will put out offsets from their roots, and thrive as well as in their native countries.

PANICLE. A Panicle is a stalk diffused into several pedicles or foot-stalks, sustaining the flowers or fruits, as in Oats, &c.

PANICUM. Tourn. Inst. R. H. 515. tab. 298. Lin. Gen. Plant. 70. Panic; in French, *Panis*.

The CHARACTERS are,

There is one flower in each chaff; the chaff opens with three valves which are oval, ending in acute points. The petals open with two oval acute-pointed valves. The flowers have three short hair-like stamina, terminated by oblong summits, and a roundish germen supporting two hair-like styles, crowned by feathered stigmas. The ger-

men afterward becomes a roundish seed, fastened to the withered petals.

This genus of plants is ranged in the second section of Linnæus's third class, which includes the plants whose flowers have three stamina and two styles.

The SPECIES are,

1. **PANICUM** (*Germanicum*) spicâ simplici cernuâ, setis brevioribus pedunculo hirsuto. *Panic with a single nodding spike, short awns, and a hairy foot-stalk.* Panicum Germanicum, five panicula minore. C. B. P. 27. *German Panic with a smaller panicle.*
2. **PANICUM** (*Italicum*) spicâ compositâ, spiculis glomeratis, setis immixtis, pedunculo hirsuto. Lin. Sp. Plant. 56. *Panic with a compounded spike, whose smaller spikes grow in clusters intermixed with awns, and a hairy foot-stalk.* Panicum Italicum five panicula majore. C. B. P. 27. *Italian Panic with a larger spike.*
3. **PANICUM** (*Indicum*) spicâ simplici longissimâ, setis hispidis, pedunculo hirsuto. *Panic with the longest single spike, prickly awns, and a hairy foot-stalk.* Panicum Indicum, spicâ longissimâ. C. B. P. 27. *Indian Panic with the longest spike.*
4. **PANICUM** (*Alopecuroidem*) spicâ tereti, involucellis bifloris fasciculato-pilosis. Flor. Zeyl. 44. *Panic with a taper spike having two flowers in each cover, and hairs growing in clusters.* Panicum Indicum altissimum, spicâ simplicibus mollibus, in foliorum alis longissimis pediculis insidentibus. Tourn. Inst. 515. *Tallest Indian Panic, with the soft single spikes proceeding from the wings of the leaves, and sitting upon very long foot-stalks.*
5. **PANICUM** (*Ceruleum*) spicâ simplici æquali, pedunculis bifloris. Prod. Leyd. 54. *Panic with an equal single spike, and two flowers growing on each foot-stalk.* Panicum Indicum, spicâ obtusâ cæruleâ. C. B. P. 7. *Indian Panic, with an obtuse blue spike.*

There are several other species of this genus than are here enumerated, some of which grow naturally in England; but as they are not cultivated, so it would be swelling this work too much if they were inserted here.

The first sort grows naturally in Germany and Hungary; of this there are three varieties, one with yellow grain, another with white, and the third has purple grains. This hath been formerly cultivated for bread, in some of the northern countries. It rises with a jointed Reed-like stalk about three feet high, and about the size of the common Reed, garnished at each joint with one Grass-like leaf a foot and a half long, and about an inch broad at the base where broadest, ending in acute points; they are rough to the touch, embracing the stalk at their base, and turn downward about half their length. The stalks are terminated by compact spikes, which are about the thickness of a man's finger at their base, growing taper toward their points, and are eight or nine inches long, closely set with small roundish grain like that of Millet. This is an annual plant, which perishes soon after the seeds are ripe.

The second sort is frequently cultivated in Italy, and other warm countries. This rises with a Reed-like stalk near four feet high, which is much thicker than that of the former; the leaves are also broader, but of the same shape. The spikes are a foot long, and twice the thickness of those of the former, but not so compact, being composed of several roundish clustered spikes; the grain is also larger, but of the same form. There are two or three varieties of this, which differ only in the colour of their grain; this is also annual.

The third sort grows naturally in both Indies; this hath a Reed-like stalk as large as a man's thumb, rising upward of five feet high; the leaves are two inches broad, and more than two feet long, of the same form with those of the former sort; the spikes at the top are a foot and a half long, very compact, and thicker than a man's thumb at the base, growing taper toward the top. The seeds are much larger than those of the other sorts, and are in some white and in others yellow.

The fourth sort grows naturally in both Indies; this hath a strong Reed-like stalk, which rises six or seven feet high, garnished with leaves more than three feet long; they are near three inches broad at their base, lessening to a point at the end, having a smooth surface; the spikes arise at the wings of the stalk; they are single, but not so compact as those of the former, having soft awns or beards; they are about six inches long, and stand upon very long foot-stalks; the grain of this is pretty large.

The fifth sort grows naturally in Peru; this rises with a Reed-like stalk six feet high, which sends out two or three branches from the sides, and is garnished with long leaves two inches broad at their base; the stalks are of a purple colour, the leaves are also inclining to the same. The spikes come out from the wings of the stalks, and at the end of the branches; they are about four or five inches long, thicker than a man's thumb, and almost equal at the point with the base. They are of a pale blue colour, having pretty long awns or beards of the same colour, as are also the seeds, which are larger and rounder than those of the other sorts.

The two first sorts are sown in several parts of Europe in the fields, as Corn, for the sustenance of the inhabitants, but it is reckoned not to afford so good nourishment as Millet; however, it is frequently used in some parts of Germany and Italy, to make cakes and bread, but the German is not so much esteemed as the Italian sort; but as it will ripen better in cold countries than that, it is generally cultivated where a better sort of grain will not succeed.

The seeds of this sort may be sown in the spring, at the same time as Barley is sown, and may be managed exactly in the same way; but this should not be sown too thick, for these seeds are very small, and the plants grow stronger, therefore require more room. The German sort doth not grow above three feet high, unless it is sown on very rich land, in which case it will rise to be four feet high; but the leaves and stems of this Corn are very large, so require to stand four or five inches apart, otherwise they will grow up weak and come to little. These large growing Corns should be sown in drills at about eighteen inches apart, so that the ground may be hoed between the rows of Corn, to keep them clear from weeds, and the stirring of the ground will greatly improve the Corn. In August the Corn will ripen, when it may be cut down and dried, and then should be housed.

The Italian Panic grows much larger than the German, and produces much larger spikes; so this should be allowed more room to grow, otherwise it will come to little. This is also later before it ripens, so it is not very proper for cold countries.

The other sorts are natives of very warm countries, where they are used by the inhabitants to make bread. These grow very large, and require a good summer, otherwise they will not ripen in this country. The seeds of this kind should be sown the latter end of March or the beginning of April, on a moderate hot-bed, and the plants should be planted out when grown to a proper size, upon a bed of light rich earth, in a warm situation. They should be planted in rows about three feet asunder, and the plants must be kept clear from weeds. When the plants are grown pretty tall, they should be supported by stakes, otherwise the winds will break them down; and when the Corn begins to ripen, the birds must be kept from it, otherwise they will soon destroy it. These sorts are preserved in some curious gardens for the sake of variety, but they are not worth cultivating for use in England. The two last sorts seldom ripen here.

PANSIES. See VIOLA TRICOLOR.

PAP AVER. Tourn. Inst. R. H. 2. tab. 119. Lin. Gen. Plant. 573. Poppy; in French, *Pavot*.

The CHARACTERS are,

The empalement of the flower is oval, indented, and composed of two almost oval, concave, obtuse leaves, which fall off. The flower has four large roundish petals which spread open, with a great number of hair-like stamina,

terminated by oblong, compressed, erect summits. In the center is placed a large roundish germen having no style, but is crowned by a plain, radiated, target-shaped stigma. The germen afterward becomes a large capsule, crowned by the plain stigma, having one cell, opening in many places at the top under the crown, and is filled with small seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, which includes those plants whose flowers have many stamina and one germen.

The SPECIES are,

1. PAP AVER (*Rheas*) capsulis glabris globosis, caule piloso multifloro, foliis pinnatifidis incis. Lin. Sp. Plant. 507. Poppy with smooth globular heads, a hairy stalk with many flowers, and wing-pointed cut leaves. *Papaver erraticum, rubrum, campestre*. J. B. 3. 395. Common red field Poppy.
2. PAP AVER (*Hybridum*) capsulis subglobosis torosis hispidis, caule folioso multifloro. Lin. Sp. Plant. 506. Poppy with globular capsules which are furrowed and prickly, and a leafy stalk bearing many flowers. *Argemone capitulo brevioris hispido*. J. B. 3. 396. *Argemone* with a shorter prickly head.
3. PAP AVER (*Argemone*) capsulis clavatis hispidis, caule folioso multifloro. Lin. Sp. Plant. 506. Poppy with nail-shaped prickly heads, and a leafy stalk bearing many flowers. *Papaver erraticum, capite longiore hispido*. Tourn. Inst. 238. Field Poppy with a longer prickly head.
4. PAP AVER (*Alpinum*) capsula hispidâ, scapo unifloro nudo hispido, foliis bipinnatis. Lin. Sp. Plant. 507. Poppy with prickly heads, and a naked prickly stalk bearing one flower, and double winged leaves. *Argemone Alpina coriandri folio*. C. B. P. 172. Alpine *Argemone* with a Coriander leaf.
5. PAP AVER (*Cambricum*) capsulis glabris oblongis, caule multifloro lævi, foliis pinnatis incis. Lin. Sp. Plant. 508. Poppy with oblong smooth heads, a smooth stalk bearing many flowers, and cut winged leaves. *Papaver luteum perenne, laciniato folio, Cambrobritannicum*. Raii Syn. Ed. 3. p. 309. Yellow, Welch, perennial Poppy, with a cut leaf.
6. PAP AVER (*Nudicaule*) capsulis hispidis, scapo unifloro nudo hispido, foliis simplicibus pinnato-sinuatis. Hort. Upsal. 136. Poppy with prickly heads, a naked rough stalk having one flower, and single leaves which are wingedly sinuated. *Papaver erraticum, luteo flore, capite oblongo hispido*. Amman. Ruth. 61. Field Poppy with a yellow flower, and an oblong prickly head.
7. PAP AVER (*Oriente*) capsulis glabris, caulibus unifloris, scabris, foliis pinnatis serratis. Hort. Upsal. 136. Poppy with smooth heads, rough leafy stalks having one flower, and sawed winged leaves. *Papaver Orientale hirsutissimum flore magno*. Tourn. Cor. 17. Most hairy eastern Poppy with a large flower.
8. PAP AVER (*Somniferum*) calycibus capsulisque glabris, foliis amplexicaulibus incis. Lin. Sp. Plant. 508. Poppy with smooth capsules and empalements, and cut leaves embracing the stalks. *Papaver hortense nigro semine, sylvestre Dioscoridis, nigrum*. Plinii. C. B. P. 170. Garden Poppy with black seeds.
9. PAP AVER (*Album*) capsulis ovatis glabris, foliis latioribus amplexicaulibus marginibus inciso-serratis. Poppy with oval smooth heads, and broader leaves embracing the stalks, which are cut on their edges like the teeth of a saw. *Papaver hortense, semine albo, sativum Dioscoridis, album*. Plinii. C. B. P. 170. Garden Poppy with white seeds, commonly called white Poppy.

The first sort is the common red Poppy, which grows naturally on arable land in most parts of England; from the flowers of this sort is drawn a simple water, a tincture, a syrup and conserve for medicinal use. It is an annual plant; from the roots rise several rough branching stalks a foot and a half high, garnished with hairy leaves five or six inches long, deeply jagged almost to the midrib, those on the lower part of the leaves being the deepest; these jags are opposite and regular, like those of the winged leaves. At the top of each stalk stand the flowers, which have oval hairy empalements, opening with

two

two valves, and soon fall away. The flowers are composed of four large roundish petals, which are narrow at their base, but spread out into a circular order; they are of a beautiful scarlet colour, and soon fall off. These appear in June, and are succeeded by oblong smooth heads, crowned by the flat target-shaped stigma, and perforated in several places at the top, filled with small purplish-coloured seeds. There are several varieties of this with double flowers, cultivated in gardens; some of them have white flowers, others have red flowers bordered with white, and some have variegated flowers; but as these varieties have been produced by culture from the seeds of the common sort, they should be included in that species. The second sort grows naturally among the Corn in many parts of England; the leaves of this sort are much smaller than those of the first, and are cut into much finer segments; the stalks are slender, a little more than a foot high, not so branching as the former. The flowers are not so large, and of a deep purple colour, very soon falling away, seldom lasting more than a whole day; these are succeeded by oblong prickly heads, filled with small black seeds. It flowers in June.

The third sort grows naturally among Corn in some parts of England, but not in so great plenty as either of the former. The leaves of this are finer cut and smaller than those of the first sort, but are not so fine as those of the second; the stalks do not rise so high as either of the former, and seldom have many branches. The flowers are not half so large as either of the former, and are of a copper colour, falling away in a few hours. These appear in May, and are succeeded by long, slender, prickly heads, which are channelled, filled with small, black, shrivelled seeds.

The fourth sort grows naturally on the Alps, among the rocks. The leaves of this are smooth and doubly winged, the segments are finely cut; the stalks rise about a foot high, sustaining one small yellow, or copper-coloured flower, which is succeeded by roundish prickly heads, filled with small seeds. This flowers about the same time as the former sort.

The fifth sort has a perennial root; it grows naturally in Wales, and also in some of the northern counties in England. I found it growing plentifully near Kirby-Lonsdale in Westmoreland. Tournefort also found this plant upon the Pyrenean mountains. The leaves of this sort are winged; the lobes are deeply cut on their edges. The stalks rise a foot high; they are smooth, and are garnished with a few small leaves of the same shape as the lower. The upper part of the stalk is naked, sustaining one large yellow flower. These appear in June, and are succeeded by oblong smooth capsules, filled with small purplish seeds.

The sixth sort grows naturally on the confines of Russia, near Tartary. The leaves of this sort are single, and sinuated almost to the midrib in form of a winged leaf; they are rough and hairy. The stalk rises near two feet high; it is slender, naked, sustaining one flower at the top, which is composed of four roundish petals of a pale yellow colour, each having a dark bottom or tail. The flowers have an agreeable scent, but are of short duration. They come out in June, and are succeeded by long rough capsules, filled with small seeds.

The seventh sort grows naturally in Armenia, from whence Dr. Tournefort sent the seeds to the royal gardens at Paris, where they succeeded, and were afterward communicated to the curious gardens in England and Holland. The root of this plant is composed of two or three strong fibres as thick as a man's little finger, which are a foot and a half long, of a dark brown on their outside, and full of a milky juice, which is very bitter and acrid. The leaves are winged, and sawed on their edges; they are a foot long, closely covered with bristly white hairs. The stalks rise two feet and a half high; they are very rough and hairy, garnished below with leaves like those at bottom, but smaller; the upper part is

naked, sustaining at the top one very large flower, of the same colour with the common red Poppy. These appear in May, and are succeeded by oval smooth capsules, filled with purplish seeds.

There are two or three varieties of this which differ only in the colour of their flowers; and I have been informed, there is a double flower of this kind, but I have not seen it. Tournefort says, the Turks eat the green heads of this Poppy, although they are very bitter and acrid.

The eighth sort is the common black Poppy, the seeds of which are sold in the shops by the title of Maw-seed. The sort with single flowers grows in the warm parts of Europe naturally; this is annual; the stalks rise three feet high; they are smooth, and divide into several branches, and are garnished with large leaves, which are smooth, and deeply cut or jagged on their edges, embracing the stalks with their base. The flowers grow on the top of the stalks; they are composed of four large roundish petals of a purplish colour, with dark bottoms, and are succeeded by oval smooth capsules filled with black seeds. It flowers in June, and the seeds ripen the latter end of August.

There are great varieties in the flowers of this sort, some having very large double flowers, which are variegated of several colours; some are red and white, others purple and white, and some are finely spotted like Carnations; so that during their short continuance in flower, there are few plants whose flowers appear so beautiful; but having an offensive scent, and being of short duration, they are not much regarded. The leaves of this sort are used as an ingredient in cooling ointments; and the heads of this were an ingredient in the syrupus c Melonio, but in the late Dispensaries they have been left out.

The ninth sort is the common white Poppy; this is cultivated in gardens for the heads, which are used in medicine. The stalks of this are large, smooth, and rise to the height of five or six feet; they branch out into several smaller, garnished with large grayish leaves, whose base embraces the stalks; they are jagged irregularly on their sides. The flowers terminate the stalks; these, when inclosed in the empalement, nod downward, but before the flowers open they are erect. The empalement of the flower is composed of two large oval leaves, of the same grayish colour as the other; these separate and soon drop off. The flower is composed of four large, roundish, white petals, which are of short duration, and are succeeded by large roundish heads as big as Oranges, flattened at both ends, having indented crowns, and are filled with small white seeds. This flowers in June, and the seeds ripen in August.

There are several varieties of this sort, which differ in the colour of their flowers and multiplicity of petals; those with beautiful flowers are preserved in gardens for ornament, but that with the single flowers only is cultivated for use. The seeds of this sort are used in emulsions, being cooling, and good in fevers and inflammatory distempers, as also for the stranguery and heat of the urine. Of the dry heads infused and boiled in water, is made the diacodium of the shops.

It has been generally supposed, that from the heads of this sort of Poppy the opium is extracted; but one of the heads which I have by me, from which opium had been extracted in Turkey, is of a different shape from those of this sort.

All the sorts of Poppy are propagated by seeds, but the fifth and seventh sorts, which have perennial roots, may be also propagated by offsets. The best time for sowing the seeds is in September, when they will more certainly grow than those which are sown in the spring; and those sorts which are annual will make larger plants, and flower better than when they are sown in the spring. The best way is to sow the seeds of the annual kinds in the places where they are to remain, and to thin the plants where they are too close; those of the large kinds should not be left nearer to each other than a foot and a half, and the smaller

forts may be allowed about half that space. The culture they will require after this, is only to keep them clean from weeds.

Those who are curious to have fine Poppies in their gardens, carefully look over their plants when they begin to flower, and cut up all those plants whose flowers are not very double and well marked, before they open their flowers, to prevent their farina mixing with their finer flowers, which would degenerate them; and it is the not being careful of this, that causes the flowers to degenerate so frequently in many places, which is often supposed to be occasioned by the ground.

The yellow Welsh Poppy requires a cool shady situation, where the plants will thrive, and produce plenty of seeds annually. If these seeds are permitted to scatter, the plants will come up better than when sown by hand; but if they are sown, it should be always in the autumn; for the seeds of this, which are sown in the spring, rarely succeed.

The best time to transplant and part the roots of this sort is in the autumn, that the plants may be well established in their new quarters, before the dry weather comes on in the spring.

The eastern Poppy will thrive either in sun or shade, for I have several of these plants growing under trees, where they have thriven many years, and flower full as well as those in an open situation, but came later in the season. This will propagate very fast by its roots, so there is no necessity for sowing the seeds, unless to procure new varieties. This sort should be transplanted at the same season as the former; and if the seeds are sown, it should be at the same time, for the reasons before given.

PAPAVER CORNICULATUM. See **GLAUCIUM.**

PAPAVER SPINOSUM. See **AGREMONE.**

PAPAYA. See **CARICA.**

PAPILIONACEOUS. A papilionaceous (or Pea-bloom) flower is so called, because in some measure it resembles a butterfly with its wings expanded. It always consists of these parts; the vexillum or standard, which is a large erect segment or petal; the alae, or two wings, which compose the sides, and the carina, or keel, which is a concave petal or segment, resembling the lower part of a boat: this keel is sometimes entire, and sometimes it consists of two petals or segments adhering pretty close together. Of this tribe are Peas, Beans, Kidney-beans, Vetches, and other leguminous plants.

PAPPOSE PLANTS are such as have their seeds covered with a down, which adheres to the upper part of the seed, and are of use to spread them when ripe, by sustaining them in the air, so that they may be conveyed to a great distance. Of this kind are the Sow-thistles, Hawkweeds, Dandelion, Starworts, &c.

PARASITICAL PLANTS are such as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow upon the ground, as the Mistletoe, &c.

PARIETARIA. Tourn. Inst. R. H. 509. tab. 289. Lin. Gen. Plant. 1020. so called from *Paries*, Lat. a wall, because it grows on old walls.] *Pellitory*; in French, *Parietaire*.

The **CHARACTERS** are,

It hath hermaphrodite and female flowers upon the same plant. There are two hermaphrodite flowers contained in a six-leaved involucre; these have a quadrifid plain empalement of one leaf, half the size of the involucre. They have no petals, but four permanent awl-shaped stamina longer than the empalement, terminated by twin summits, with an oval germen supporting a slender coloured style, crowned by a pencil-shaped stigma. The germen afterward turns to an oval seed wrapped up in the empalement. The female flowers have no stamina, but in other respects are the same as the hermaphrodite.

This genus of plants is ranged in the first section of Linnæus's twenty-third class, which contains those plants which have hermaphrodite and female flowers on the same plant.

The **SPECIES** are,

1. **PARIETARIA (Officinalis)** foliis lanceolato-ovatis alternis. Hort. Uplal. 38. *Pellitory with oval spear-shaped leaves, placed alternately.* *Parietaria officinarum* & *Dioscoridis.* C. B. P. 121. *The official Pellitory of Dioscorides.*

2. **PARIETARIA (Judiaca)** foliis ovatis caulibus erectiusculis, calycibus trifloris, corollis hermaphroditis, defloratis elongato-cylindricis. Lin. Sp. 1492. *Pellitory with oval leaves, an erect stalk, and three flowers in each cup, which are hermaphrodite.* *Parietaria minor* *Ocimi folio.* C. B. P. 121. *Smaller Pellitory with a Basil leaf.*

The first sort grows naturally in Germany and Holland, but was not in England till the year 1727, when I brought it here. This is supposed to be the true sort which is recommended by the ancients to be used in medicine; it hath a thick perennial root, composed of fleshy reddish fibres, from which arise many stalks a foot and a half high, garnished with hairy, oval, spear-shaped leaves, about two inches long, and one broad in the middle, having several veins. The flowers come out in small clusters on the side of the stalks; they are small, of an herbaceous colour, so make no figure. These appear in succession all the summer months, and the seeds ripen accordingly, which are cast out to a distance with an elasticity when ripe.

The second sort grows plentifully on old walls, and the sides of dry banks in most parts of England; this differs from the former in having shorter stalks, and smaller oval leaves. The flowers are also less, and are in smaller clusters; in other respects they are the same.

They may be propagated in plenty from a single plant, which, if permitted to scatter its seeds, will fill the ground about it with young plants, for the seeds are very difficult to collect, as they are thrown out of their covers as soon as they are ripe.

There are three or four other species of this genus, but as they have little beauty and are of no use, so are not cultivated in gardens.

PARIS. Lin. Gen. Plant. 449. *Herba Paris.* Tourn. Inst. R. H. 233. tab. 117. *True-love, or One-berry.*

The **CHARACTERS** are,

The empalement of the flower is permanent, and composed of four leaves, which expand in form of a cross. The flower also hath four leaves, which spread open in the same manner, and are permanent. In the center of the flower is situated a roundish four-cornered germen, supporting four spreading styles, crowned by single summits. This is attended by eight stamina, each having an oblong summit, fastened by threads on each side to the stamina. The germen afterward changes to a roundish berry, having four cells which are filled with seeds.

This genus of plants is ranged in the fourth section of Linnæus's eighth class, which includes the plants whose flowers have eight stamina and four styles.

We know but one **SPECIES** of this genus, viz.

PARIS (Quadrifolia) foliis quaternis. Flor. Lapp. 155. *Herb Paris, True-love, or One-berry.*

This plant grows wild in moist shady woods in divers parts of England, but especially in the northern counties, and it is with great difficulty preserved in gardens. The only method to procure it, is to take up the plants from the places where they grow wild, preserving good balls of earth to their roots, and plant them in a shady moist border, where they may remain undisturbed, in which situation they will live some years; but as it is a plant of little beauty, it is rarely preserved in gardens.

PARKINSONIA. Plum. Nov. Gen. 25. tab. 3. Lin. Gen. Plant. 460.

The **CHARACTERS** are,

The empalement of the flower spreads open; it is of one leaf, indented in five parts at the top. The flower has five almost equal petals placed circularly; the four upper are oval, the under is kidney-shaped. It has ten declining stamina terminated by oblong summits, and a long taper germen with scarce any style, crowned by an obtuse stigma.

The

The germen afterward becomes a long taper pod with swelling joints, in each of which is lodged one oblong seed.

This genus of plants is ranged in the first section of Linnæus's tenth class, which includes those plants whose flowers have ten stamina and one style.

We know but one SPECIES of this genus, viz.

PARKINSONIA (*Aculeata*.) Parkinsonia. Hort. Cliff. 57.

Parkinsonia aculeata, foliis minutis, uni costæ adnexis. Plum. Nov. Gen. 25. Prickly Parkinsonia with, very small leaves, which are fastened to one middle rib.

This plant was discovered by Father Plumier in America, who gave it this name in honour of Mr. John Parkinson, who published an Universal History of Plants in English, in the year 1640.

It is very common in the Spanish West-Indies, but of late years it has been introduced into the English settlements in America, for the beauty and sweetness of its flowers. This, in the countries where it grows naturally, rises to be a tree of twenty feet high or more, and bears long slender bunches of yellow flowers, which hang down after the same manner as the Laburnum. These flowers have a most agreeable sweet scent, so as to perfume the air to a considerable distance round about the trees; for which reason, the inhabitants of the West-Indies plant them near their habitations. And though this plant has not been introduced many years into the English settlements, yet it is now become so common in all the islands, that but few houses are without some of the trees near it; for it produces flowers and seeds in plenty in about two years from seed, so that it may soon be made common in all hot countries; but in Europe it requires a stove, otherwise it will not live through the winter.

This plant is propagated by seeds, which should be sown in small pots filled with light fresh earth early in the spring, and the pots must be plunged into a hot-bed of tanners bark, where, in about three weeks or a month's time, the plants will come up, when they should be kept clear from weeds, and frequently refreshed with a little water. In a little time these plants will be fit to transplant, which should be done very carefully, so as not to injure their roots. They must be each planted into a separate halfpenny pot filled with light fresh earth, and then plunged into the hot-bed again, observing to stir up the tan; and if it hath lost its heat, there should be some fresh tan added to renew it again. Then shade the plants from the heat of the sun, until they have taken new root; after which time they should have fresh air admitted to them every day, in proportion to the warmth of the season. With this management the plants will grow so fast, as to fill the pots with their roots by the beginning of July, at which time they should be shifted into pots a little larger than the former, and plunged again into the bark-bed to forward their taking new root; after which it will be the best way to inure the plants by degrees to bear the open air, that they may be hardened before winter; for if they are kept too warm in winter, the plants will decay before the next spring. The only method by which I have succeeded in keeping this plant through the winter, was by hardening them in July and August to bear the open air; and in September I placed them on shelves in the dry stove, at the greatest distance from the fire, so that they were in a very temperate warmth; and there they retained their leaves all the winter, and continued in health, when those which were placed in a warmer situation, as also those in the green-house, were entirely destroyed, but these seldom survived the second winter.

PARNASSIA. Tourn. Inst. R. H. 246. tab. 127. Lin. Gen. Plant. 345. Grass of Parnassus.

The CHARACTERS are,

The flower hath a permanent spreading empalement, cut into five parts. The flower has five roundish, concave, spreading petals, which have five heart-shaped concave nectariums, and five stamina terminated by depressed summits, with a large oval germen having no style, but four obtuse permanent stigmas in their place. The germen afterward turns

to an oval four-cornered capsule with one cell, containing several oblong seeds.

This genus of plants is ranged in the fourth section of Linnæus's fifth class, which includes the plants whose flowers have five stamina and four styles.

The SPECIES are,

1. **PARNASSIA** (*Palustris*.) Parnassus Grass. Parnassia palustris & vulgaris. Inst. R. H. Common Marsh Grass of Parnassus.

2. **PARNASSIA** (*Pleno flore*) vulgaris flore pleno. Common Grass of Parnassus, with a double flower.

The former of these sorts grows wild in moist meadows in several parts of England, but particularly in the north; but it doth not grow in the neighbourhood of London, any nearer than on the other side of Watford, in the low meadows by Cassioberry, where it is in pretty great plenty.

The other sort is an accidental variety of the former, which has been discovered wild, and transplanted into gardens. This is but rarely to be found, being in very few gardens at present.

These plants may be taken up from the natural places of their growth, with balls of earth to their roots, and planted into pots filled with pretty strong, fresh, undunged earth, and placed in a shady situation, where, if they are constantly watered in dry weather, they will thrive very well, and flower every summer; but if the plants are planted in the full ground, it should be in a very moist shady border, otherwise they will not live; and these should be as duly watered as those in the pots in dry weather, to make them produce strong flowers.

They may be propagated by parting their roots, which should be done in March, before they put out new leaves; but the roots should not be divided too small, for that will prevent their flowering the following summer. These roots should always be planted in pretty strong fresh earth, for they will not thrive in a light rich soil. In the spring they must be constantly watered, if the season should prove dry, otherwise they will not flower; nor should they be parted oftener than every third year, to have them strong. These plants flower in July, and their seeds are ripe the latter end of August.

It is called Parnassus, from Mount Parnassus, on which it was supposed to grow; and from the cattle feeding on it, it was called a Grass, though the plant has no resemblance to any of the Grass kind, but is more like the Ranunculus in flower, and the leaves are pretty broad, oblong, and smooth.

PARONYCHIA. See ILLECEBRUM.

PARSLEY. See APIUM.

PARSNIP. See PASTINACA.

PARTERRE is a level division of ground, which, for the most part, faces the south and best front of a house, and is generally furnished with greens, flowers, &c.

There are several sorts of Parterres, as plain Grass with borders, and Parterres of embroidery, &c.

Plain Parterres are more beautiful in England than in any other countries, by reason of the excellency of our turf, and that decency and unaffected simplicity that it affords to the eye of the spectator.

Others are cut into shell and scroll-work, with sand-alleys between them, which are the finest Parterre works esteemed in France.

As to the general proportion of Parterres, an oblong or long square is accounted the most proper figure for a Parterre; because by the rules of perspective, or the natural declension of the visual rays in optics, a long square sinks almost to a square, and an exact square appears much less than it really is, therefore a Parterre should not be less than twice as long as it is broad; twice and a half is accounted a very good proportion, and it is very rare that three times is exceeded.

As to the breadth of a Parterre, it is to take its dimensions from the breadth of the front of the house. If the front of the house is one hundred feet long, the breadth of the Parterre should be one hundred and

fifty

fifty feet; and if the front of the house be two hundred feet, the Parterre should be fifty feet broader; but where the front of the house exceeds the breadth of the Parterre, it will be a good proportion to make the Parterre of the same dimensions with the front. Some do not approve of making Parterres very broad, because it makes them appear too short; when nothing is more pleasing to the eye, than a contracted regular conduct and view, as soon as the person goes out of a house or building; and a forward direct view is the best, whether it be either Parterre or lawn, or any other open space, either two, three, or four-fold in the width; and for that reason, those designs may justly be disapproved, by which the nobleness of the view is marred at the immediate entrance into the garden, the angle of light being broken and confused.

The making of Parterres too large causes a great expence, and at the same time occasions a diminution of wood, which is the most valuable part of a garden. As to the adorning and furnishing these Parterres, whether it be plain or with embroidery, that depends much upon the form of them, and therefore must be left to the judgment and fancy of the designer.

PARTHENIUM. Lin. Gen. Plant. 939. Partheniastrum. Nissol. Act. Par. 1711. Dill. Gen. 13. Bastard Feverfew.

The CHARACTERS are,

It hath a flower composed of hermaphrodite florets and female half florets, which are inclosed in a common five-leaved spreading empalement. The hermaphrodite flowers which form the disk, have one tubulous petal cut into five parts at the brim; they have five hair-like stamina the length of the tube, terminated by thick summits. The germen is situated below the floret, and is scarce visible, supporting a slender style having no stigma; these florets are barren. The female florets which compose the rays or border, are stretched out on one side like a tongue; these have a large, heart-shaped, compressed germen, with a slender style crowned by two long spreading stigmas. These are succeeded by one heart-shaped compressed seed.

This genus of plants is ranged in the fifth section of Linnæus's twenty-first class, which includes those plants which have male and female, or hermaphrodite flowers in the same plants, whose male or hermaphrodite flowers have five stamina.

The SPECIES are,

1. **PARTHENIUM** (*Hysterophorus*) foliis composito-multifidis. Lin. Hort. Cliff. 442. *Parthenium with many-pointed compound leaves. Partheniastrum artemisiæ folio, flore albo.* Hort. Chelf. 152. *Bastard Feverfew, with a Mugwort leaf.*
2. **PARTHENIUM** (*Integrifolium*) foliis ovatis crenatis. Lin. Hort. Cliff. 442. *Parthenium with oval crenated leaves. Partheniastrum helenii folio.* Hort. Elth. 302. tab. 225. *Bastard Feverfew with an Elecampane leaf.*

The first sort grows wild in great plenty in the island of Jamaica, and in some other of the English settlements in the West-Indies, where it is called wild Wormwood, and is used by the inhabitants as a vulnerary herb.

The second sort grows plentifully in several parts of the Spanish West-Indies, from whence the seeds have been brought to Europe.

The first is an annual plant, which may be propagated by sowing the seeds on a hot-bed early in the spring; and when the plants come up, they should be transplanted on another hot-bed, at about five or six inches distance, observing to water and shade them until they have taken new root; after which time they must have a pretty large share of fresh air in warm weather, by raising the glasses of the hot-bed every day, and they must be duly watered every other day at least. When the plants have grown so as to meet each other, they should be carefully taken up, preserving a ball of earth to their roots, and each planted into a separate pot filled with light rich earth; and if they are plunged into a moderate hot-bed, it will greatly facilitate their taking fresh root; but where this conveniency is wanting, the plants

should be removed to a warm sheltered situation, where they must be shaded from the sun until they have taken new root; after which time they may be exposed, with other hardy annual plants in a warm situation, where they will flower in July, and their seeds will ripen in September. But if the season should prove cold and wet, it will be proper to have a plant or two in shelter, either in the stove, or under tall frames, in order to have good seeds, if those plants which are exposed should fail, whereby the species may be preserved.

The second sort is a perennial plant, which dies to the ground every autumn, and shoots up again the following spring. The seeds of this sort were sent me by my good friend Dr. Thomas Dale, from South Carolina, where the plants grow wild. This may be propagated by parting the roots in autumn, and may be planted in the full ground, where it will abide the cold of our ordinary winters very well. This sort flowers in July, but seldom produces good seeds in England.

These plants make no great appearance, so are seldom cultivated but for the sake of variety.

PASQUE-FLOWER. See PULSATILLA.

PASSERINA. Lin. Gen. Plant. 440. Thymelæa. Tourn. Inst. R. H. 594. Pluk. Sanamunda. Clus. Sparrow-wort.

The CHARACTERS are,

The flower has no empalement; it has one withered petal, having a slender cylindrical tube swelling below the middle, and divided into four parts at the top, which spread open. It hath eight bristly stamina sitting on the top of the tube, terminated by erect summits almost oval. It has an oval germen under the tube, having a slender style rising on one side of the top of the germen, crowned by a beaded stigma, set with prickly hairs on every side. The germen afterward turns to an oval seed pointed at both ends, inclosed in a thick oval capsule of one cell.

This genus of plants is ranged in the first section of Linnæus's eighth class, which includes those plants whose flowers have eight stamina and one style.

The SPECIES are,

1. **PASSERNIA** (*Filiformis*) foliis linearibus convexis quadrifariam imbricatis, ramis tomentosis. Lin. Sp. Plant. 559. *Sparrow-wort with linear convex leaves imbricated four ways, and downy branches. Thymelæa Ethiopica, passerinæ foliis.* Breyn. Cent. 10. fig. 6. *Ethiopian Spurge Laurel, with Sparrow-wort leaves.*
2. **PASSERINA** (*Hirsuta*) foliis carnosissimis extus glabris, caulibus tomentosis. Lin. Sp. Plant. 559. *Sparrow-wort with fleshy leaves, which are smooth on their outside, and downy stalks. Sanamunda 3. Clus. Hist. 1. p. 89. The third Sanamunda of Clusius.*
3. **PASSERNIA** (*Ciliata*) foliis lanceolatis subciliatis erectis, ramis nudis. Lin. Sp. Plant. 559. *Sparrow-wort with spear-shaped erect leaves having small hairs and naked branches. Sanamunda 1. Clus. Hist. 88. The first Sanamunda of Clusius.*
4. **PASSERNIA** (*Uniflora*) foliis linearibus oppositis, floribus terminalibus solitariis, ramis glabris. Lin. Sp. Plant. 560. *Sparrow-wort with linear leaves placed opposite, single flowers terminating the branches, and smooth stalks. Thymelæa ramosa, linearibus foliis angustis, flore solitario.* Burm. Afr. 131. tab. 48. fig. 1. *Branching Spurge Laurel, with narrow linear leaves and a single flower.*

The first sort grows naturally at the Cape of Good Hope, from whence it was first brought to the gardens in Holland. This rises with a shrubby stalk five or six feet high, sending out branches the whole length, which, when young, grow erect, but as they advance in length, they incline toward an horizontal position; but more so, when the small shoots toward the end are full of flowers and seed-vessels, which weigh down the weak branches from their upright position. The branches are covered with a white down like meal, and are closely garnished with very narrow leaves which are convex, and lie over each other in four rows like the scales of fish, so as that the young branches seem as if they were four-cornered.

The

The flowers come out at the extremity of the young branches, from between the leaves on every side; they are small and white, so make but little appearance, and are succeeded by small seed-vessels, which seem withered and dry. The flowers come out in June and July, and the seeds ripen in the autumn.

This plant may be propagated by cuttings during the summer months, which should be planted in a bed of loamy earth, and closely covered with a bell or hand-glass to exclude the air, shading them every day from the sun, and refreshing them now and then with water. With this treatment the cuttings will have taken root in about two months, when they may be taken up, and each planted in a small pot filled with soft loamy earth, placing them in the shade till they have taken new root; then they may be removed into a sheltered situation, where they may remain till October, when they must be placed in the green-house, for they will not live in the open air through the winter in England; but they require no other treatment, than Myrtles and other hardy green-house plants, which is to screen them from frost. As this plant retains its verdure all the year, so it makes a pretty variety in the green-house in winter.

It may also be propagated by seeds, which if sown in the autumn soon after they are ripe, will more certainly succeed, than at any other season of the year. The seeds should be sown in small pots filled with light earth, and if they are plunged into an old bed of tanners bark, under a common frame in winter, the plants will come up in the spring, and should then be treated in the same manner as those raised from cuttings; but the seedling plants will grow more erect, and appear handsomer than those propagated by cuttings.

The second sort grows naturally in Spain and Portugal; this hath shrubby stalks, which rise to a greater height than the former; the branches grow more diffused, and are covered with a mealy down, garnished with short, thick, succulent leaves, lying over each other like the scales of fish; they are smooth and green on their outside, but downy on their inner. The flowers are small and white, like those of the former, and appear about the same time. This plant will live abroad in ordinary winters, if it is planted in a dry soil and a warm situation; but in hard frosts the plants are frequently destroyed, therefore one or two plants should be kept in pots, and sheltered in winter to preserve the species. This may be propagated by cuttings, in the same way as the former sort. The third sort grows naturally in Spain and Portugal, as also at the Cape of Good Hope. This hath a shrubby stalk rising five or six feet high, sending out many branches which are naked to their ends, where they are garnished with oblong leaves standing erect, which have hairy points. The flowers are small, white, and come out between the leaves at the end of the branches; they appear in June, but are not succeeded by seeds in England. This may be propagated by cuttings as the two former, and requires the same treatment.

The fourth sort grows naturally at the Cape of Good Hope; it hath a low shrubby stalk, which seldom rises more than a foot high, dividing into many slender branches, which are smooth, and spread out on every side, garnished with very narrow leaves placed opposite; they are of a dark green, and have the appearance of those of the Fir-tree, but are narrower. The flowers come out singly at the end of the branches, which are larger than those of the former, and the upper part of the petals is spread open almost flat; they are of a purple colour, and appear about the same time as the former. This may be propagated by cuttings as the other sorts, and the plants must be treated as the first sort.

PASSIFLORA. Lin. Gen. Plant. 910. Granadilla. Tourn. Inst. R. H. 240. tab. 124. Passion-flower; in French, *Fleur de la Passion*.

The CHARACTERS are,

The flower has a plain coloured empalement of five leaves, and five half spear-shaped petals, which are large, plain

and obtuse. The nectarium hath a triple crown; the outer, which is longer, is fastened to the inside of the petal, but is larger and compressed above. It has five oval-shaped stamina, fastened at their base to the column of the style annexed to the germen, spreading out horizontally, and terminated by oblong, obtuse, incumbent summits. The style is an erect cylindrical column, upon whose top sits an oval germen, with three smaller styles which spread out, crowned by beaded stigmas. The germen afterward becomes an oval fleshy fruit with one cell, sitting at the end of the style, filled with oval seeds, fastened longitudinally to the skin or shell.

This genus of plants is ranged in the fourth section of Linnæus's twentieth class; which includes those plants whose male and female parts are joined together, and their flowers have five stamina.

The SPECIES are,

1. **PASSIFLORA** (*Incarnata*) foliis trilobis ferratis. Amœn. Acad. vol. i. p. 230. *Passion-flower with leaves having three sawed lobes.* Granadilla Hispanis, flos passionis Italis. Hern. Mex. 888. *The Granadilla of the Spaniards, and the Passion-flower of the Italians, commonly called three-leaved Passion-flower.*
2. **PASSIFLORA** (*Cærulea*) foliis palmatis integerrimis. Amœn. Acad. vol. i. p. 231. *Passion-flower with hand-shaped entire leaves.* Granadilla pentaphyllos, flore cæruleo magno. Boerh. Ind. alt. 2. p. 81. *Five-leaved Passion-flower, with a large blue flower, or the most common Passion-flower.*
3. **PASSIFLORA** (*Lutea*) foliis trilobis cordatis æqualibus obtusis glabris integerrimis. Amœn. Acad. vol. i. p. 224. *Passion-flower with heart-shaped leaves having three equal lobes, which are smooth, obtuse, and entire.* Granadilla folio tricuspidi, flore parvo flavescente. Tourn. Inst. R. H. 240. *Passion-flower with a three-pointed leaf, and a small yellowish flower.*
4. **PASSIFLORA** (*Glabra*) foliis trilobis integerrimis, lobis sub lanceolatis, intermedio productiore. Amœn. Acad. vol. i. p. 229. *Passion-flower with leaves having three entire lobes, which are somewhat spear-shaped, and have the middle one longer than the others.* Flos passionis minor, folio in tres lacinias non ferratis profundius diviso, flore luteo. Sloan. Cat. Jam. 104. *Smaller Passion-flower, with a leaf deeply divided into three segments which are not sawed, and a yellow flower.*
5. **PASSIFLORA** (*Suberosa*) foliis trilobis integerrimis glabris, cortice suberoso. Amœn. Acad. 1. 226. *Passion-flower with leaves having three entire smooth lobes, and a Cork-like bark.* Flos passionis Curassavicus, folio glabro, trilobato, & angusto, flore flavescente omnium minimo. Par. Bat. Pluk. Alm. 282. *Passion-flower of Curassao, with a smooth leaf having three lobes, and the least yellow flower.*
6. **PASSIFLORA** (*Olivæforma*) foliis hastatis glabris, petalis florum angustioribus. *Passion-flower with halbert-pointed smooth leaves, and narrow petals to the flowers.* Granadilla folio amplo tricuspidi, fructu olivæforma. Tourn. Inst. R. H. 240. *Passion-flower with a large three-pointed leaf, and an Olive-shaped fruit.*
7. **PASSIFLORA** (*Fœtida*) foliis trilobis cordatis pilosis, involucris multifido-capillaribus. Amœn. Acad. 1. p. 228. *Passion-flower with leaves having three hairy lobes, and the involucre of the flower composed of many pointed hairs.* Granadilla fœtida, folio tricuspidi villosa, flore albo. Tourn. Inst. R. H. 240. *Stinking Passion-flower with a hairy three-pointed leaf, and a white flower.*
8. **PASSIFLORA** (*Variegata*) foliis hastatis pilosis amplioribus, involucris multifido capillaribus. *Passion-flower with the largest halbert-pointed hairy leaves, and empalements composed of many-pointed hairs.* Granadilla fœtida, folio tricuspidi villosa, flore purpureo variegato. Tourn. Inst. R. H. 241. *Stinking Passion-flower with a hairy three-pointed leaf, and a flower variegated with purple.*
9. **PASSIFLORA** (*Holosericea*) foliis trilobis, basi utrinque denticulo reflexo. Amœn. Acad. 1. p. 229. *Passion-flower with leaves having three lobes, a little indented on each side the base, which is reflexed.* Granadilla folio hastato holoserico, petalis candicantibus, fimbriis ex purpureo & luteo variis. Martyn. Dec. 51. *Passion-flower with a silky halbert-pointed leaf, and flowers having*
white

white petals, which are variegated with a purple and yellow colour.

10. PASSIFLORA (*Capfularis*) foliis bilobis cordatis oblongis petiolatis. Lin. Sp. Plant. 957. *Passion-flower with oblong heart-shaped leaves, having two lobes standing upon foot-stalks.* Granadilla flore suaverubente folio bicorni. Tourn. Inst. R. H. 241. *Passion-flower with a soft red flower, and a leaf ending with two horns.*
11. PASSIFLORA (*Vespertillio*) foliis bilobis, basi rotundatis biglandulosis, lobis acutis divaricatis, subtus punctatis. Amœn. Acad. 1. 223. *Passion-flower having two lobes, and two glands at the base of their leaves, whose lobes are acute, spread from each other, and spotted on their under side.* Granadilla bicornis, flore candido, filamentis intortis. Hort. Elth. 164. tab. 137. *Passion-flower with a two-horned leaf, a white flower, and intorted filaments.*
12. PASSIFLORA (*Normalia*) foliis bilobis, basi emarginatis, lobis linearibus obtusis divaricatis, intermedio obsolete mucronato. Amœn. Acad. 5. 248. *Passion-flower with leaves having two linear obtuse lobes, which are indented at the base, and have foot-stalks.* Granadilla que Coanepilli seu Contrayerva. Hernand. *Passion-flower, called Coanepilli or Contrayerva, by Hernandes.*
13. flower with ample heart-shaped leaves, whose foot-stalks have six glands, and a square winged stalk.

The first sort grows naturally in Virginia and other parts of North America; this was the first known in Europe of all the species, but was not very common in the English gardens till of late years. The root of this plant is perennial, but the stalk is annual in North America, dying to the ground every winter, as it also does in England, unless it is placed in a stove. The stalks of this are slender, rising about four or five feet high, having tendrils or claspers at each joint, which fasten themselves about whatever plant stand near them, whereby the stalk is supported. At each joint comes out one leaf upon a short foot-stalk; these have for the most part three oblong lobes, which join at their base, but the two side lobes are sometimes divided part of their length into two narrow segments, so as to resemble a five-lobed leaf; they are thin, of a light green, and slightly sawed on their edges. The flowers are produced from the joints of the stalk at the foot-stalks of the leaves; these have long slender foot-stalks succeeding each other, as the stalks advance in height, during the summer months. The involucre of the flower is composed of five oblong blunt-pointed leaves, of a pale green; these open and disclose five more leaves or petals, which are white, having a fringe or circle of rays of a double order round the style, of a purple colour, the lower row being the longest. In the center of this arises the pillar-like style, with the roundish germen at the top, surrounded at the bottom, where it adheres to the style, with five flattish stamina which spread out every way, and sustain each of them an oblong summit which hang downward, and on their under side are covered with a yellow farina. The flowers have an agreeable scent, but are of short duration, opening in the morning, and fade away in the evening, never opening again, but are succeeded by fresh flowers, which come out at the joints of the stalk above them. When the flowers fade, the roundish germen swells to a fruit as large as a middling Apple, which changes to a pale Orange colour when ripe, inclosing many oblong rough seeds inclosed in a sweetish pulp. This sort is usually propagated by seeds which are brought from America, for the seeds do not often ripen in England; though I have sometimes had several fruit perfectly ripe on plants, which were plunged in a tan-bed under a deep frame; but those plants which are exposed to the open air, do not produce fruit here. The seeds should be sown upon a moderate hot-bed, which will bring up the plants much sooner than when they are sown in the open air, so they will have more time to get strength before winter. When the plants are come up two or three inches high, they should be carefully taken up, and each planted in a separate small pot filled with good kitchen-garden earth, and plunged into a moderate hot-bed to forward their taking new root; after which they should be gradually inured to bear the open air, to which they should be exposed in summer, but in the autumn they must be placed under a garden-frame to screen them from the frost; but they should have the free air at all times in mild weather. The spring following some of these plants may be turned out of the pots, and planted in a warm border, where, if they are covered with tanners bark every winter to keep out the frost, they will live several years, their stalks decaying in the autumn, and new ones arise in the spring, which in warm seasons will flower very well. If those plants which are continued in pots, are plunged into a tan-bed, some of them may produce fruit; and, if the stalks of these are laid down in the beginning of June, into pots of earth plunged near them, they will take root by the end of August, so that the plants may be easily propagated this way. The second sort has not been many years in England, but is now the most common. This grows naturally in the Brasils, yet is hardy enough to thrive in the open air here, and is seldom injured except in very severe winters, which commonly kills the branches to the ground, and sometimes destroys the roots; this rises

rises in a few years to a great height, if they have proper support. I have seen some of these plants, whose branches were trained up more than forty feet high. The stalks will grow almost as large as a man's arm, and are covered with a purplish bark, but do not become very woody. The shoots from these stalks are often twelve or fifteen feet long in one summer; they are very slender, so must be supported, otherwise they will hang to the ground, intermix with each other, and appear very unsightly. These are garnished at each joint with one hand-shaped leaf, composed of five smooth entire lobes, the middle one, which is the longest, being almost four inches long, and one broad in the middle, the other are gradually shorter, and the two outer lobes are frequently divided on their outer side into two smaller lobes or segments. Their foot-stalks are near two inches long, and have two small leaves or ears embracing the stalks at their base, and from the same point comes out a long clasper, which twists round the neighbouring plants, whereby the stalks are supported. The flowers come out at the same joint as the leaves; these have foot-stalks almost three inches long. The flowers have an outer cover, composed of three concave oval leaves, of a paler green than the leaves of the plant, which are little more than half the length of the empalement, which is composed of five oblong blunt leaves, of a very pale green; within these are five petals, nearly of the same shape and size with the empalement, standing alternately between them. In the center of the flower arises a thick club-like column about an inch long, on the top of which sits an oval germen, from whose base spreads out five awl-shaped horizontal stamina, which are terminated by oblong broad summits fastened in the middle of the stamina, hanging downward; these may be moved round without separating from the stamina, and their under surface is charged with yellow farina; on the side of the germen arise three slender purplish styles near an inch long, spreading from each other, terminated by obtuse stigmas. Round the bottom of the column are two orders of rays; the inner, which is the shortest, inclines toward the column the outer, which is near half the length of the petals, spread open flat upon them; these rays are composed of a great number of thread-like filaments, of a purple colour at bottom, but are blue on the outside. The flowers have a faint scent, and continue but one day; after they fade, the germen on the top of the column swells to a large oval fruit about the size and shape of the Mogul Plum, and when ripe is of the same pale yellow colour, inclosing a sweetish disagreeable pulp, in which are lodged oblong seeds. This plant begins to flower early in July, and there is a succession of flowers daily, till the frost in autumn puts a stop to them.

It may be propagated by seeds, which should be sown in the same manner as those of the first sort, and the plants treated in the same way till the following spring, when they should be turned out of the pots, and planted against a good aspected wall, where they may have height for their shoots to extend, otherwise they will hang about and entangle with each other, so make but an indifferent appearance; but where buildings are to be covered, this plant is very proper for the purpose. After they have taken good root in their new quarters, the only care they will require, is to train their shoots up against the wall, as they extend in length, to prevent their hanging about, and if the winter proves severe, the surface of the ground about their roots should be covered with mulch to keep the frost from penetrating of the ground; and if the stalks and branches are covered with mats, Peas-haulm, straw, or any such light covering, it will protect them in winter against severe frosts; but this covering must be taken off in mild weather, otherwise it will cause the branches to grow mouldy, which will be more injurious to them than the cold. In the spring the plants should be trimmed, when all the small weak shoots should be entirely cut off, and the strong ones shortened to about four or five feet long,

which will cause them to put out strong shoots for flowering the following year.

This plant is, also propagated by laying down the branches, which in one year will be well rooted, so may be taken off from the old plants, and transplanted, where they are designed to remain. The cuttings of this will also take root, if they are planted in a loamy soil not too stiff, in the spring, before they begin to shoot. If these are covered with bell or hand-glasses to exclude the air, they will succeed much better than when they are otherwise treated; but when the cuttings put out shoots, the air should be admitted to them, otherwise they will draw up weak and spoil, and they must be afterwards treated as the layers. Those plants which are propagated by layers or cuttings, do not produce fruit so plentifully as the seedling plants; and I have found the plants which have been propagated two or three times, either by layers or cuttings, seldom produce fruit, which is common to many other plants.

If in very severe winters the stalks of these plants are killed to the ground, the roots often put out new stalks the following summer, therefore they should not be disturbed; and where there is mulch laid on the ground about their roots, there will be little danger of their being killed, although all the stalks should be destroyed.

There is a variety of this; the lobes of the leaves are much narrower, and are divided almost to the bottom. The flowers come later in the summer; the petals of the flowers are narrower, and of a purer white, but I believe it is only a feminal variation of the other, so not worthy of being enumerated.

The third sort grows naturally in Virginia, and also in Jamaica; this hath a perennial creeping root, sending up many weak stalks about three or four feet high, which are garnished with leaves shaped very like those of Ivy, and are almost as large, but of a pale green and very thin consistence. The flowers come out from the wings of the stalk upon slender foot-stalks an inch and a half long, and at their base arise very slender tendrils, which clasp round any neighbouring support. The flowers are of a dirty yellow colour, and not larger than a six-pence when expanded, so make no great appearance. This may be propagated by its creeping roots, which may be parted in April, and planted where they are to remain. This sort will live in a warm border, if treated in the same way as is directed for the first sort. Some of these plants lived many years in the Chelsea Garden in a border to a south-west aspect, but in the year 1740 they were killed by the frost.

The fourth sort grows naturally in Jamaica; this hath a perennial root, from which arise several slender stalks four or five feet high, which have joints four or five inches asunder; at each of these come out one leaf, a tendril, and a flower. The leaves have three lobes; the middle one is three inches long, and almost an inch broad in the middle; the two side lobes are about two inches long, and three quarters of an inch broad, of a light green colour, and thin. The flowers are smaller than those of the last mentioned, and are of a greenish colour; these are succeeded by oval fruit, about the size of small Olives, which turn purple when they are ripe.

The fifth sort grows naturally in most of the West-India islands; this rises with a weak stalk to the height of twenty feet. As the stalks grow old, they have a thick fungous bark like that of the Cork-tree, which cracks and splits. The smaller branches are covered with a smooth bark, and garnished with smooth leaves at each joint, sitting upon very short foot-stalks; these have three lobes, the middle one being much longer than those on the sides, so that the whole leaf has the form of the point of those halberts used by the yeomen of the guards. The flowers are small, of a greenish yellow colour, and are succeeded by small oval fruit of a dark purple colour when ripe.

The sixth sort grows naturally in the West-Indies; this hath a perennial root, from which arise several slender

slender stalks, which rise eight or ten feet high, garnished with smooth green leaves standing upon slender foot-stalks. These are but slightly indented into three lobes, which end in acute points, and are shaped like the points of halberts, the middle one standing obliquely to the foot-stalk. The flowers come out from the wings of the leaves on very short foot-stalks; they are of a pale yellow. The petals of the flowers are very narrow, and longer than those of the two former sorts; the fruit is smaller and of an oval form, changing to a dark purple when ripe.

The seventh sort grows naturally in most of the islands in the West-Indies, where the inhabitants of the British islands call it Love in a Mist. The root of this is annual; the stalks rise five or six feet high when they are supported; they are channelled and hairy. The leaves are heart-shaped, divided into three lobes, the middle lobe being three inches long, and one and a half broad; the two side lobes are short but broad; they are covered with short brown hairs. The tendrils come out at the same place as the leaves, as do also the flowers, whose foot-stalks are two inches long, hairy, and pretty strong. The empalement of the flower is composed of slender hairy filaments, which are wrought like a net; these are longer than the petals of the flower, and turn up round them, so that the flowers are not very conspicuous at a distance. These are white, and of short duration; their structure is the same with the other sorts, and they are succeeded by roundish oval fruit about the size of an ordinary Golden Pippin, of a yellowish green colour, inclosed with a netted empalement. This plant is propagated by seeds, which should be sown upon a hot-bed early in the spring, and when the plants are fit to remove, they should be each transplanted into a small pot filled with light kitchen-garden earth, and plunged again into a hot-bed, observing to shade them from the sun till they have taken new root; after which time they must be treated in the same way as other plants from the same country, shifting them into larger pots as their roots increase; and when the plants are too tall to remain under the glasses of the hot-bed, they should be removed into an airy glass-case, where they should have the free air admitted to them in warm weather, but screened from the cold. In this situation the plants will flower in July, and their seeds will ripen in the autumn. The whole plant has a disagreeable scent when touched.

There is a variety of this, if it is not a distinct species, with hairy leaves not so broad as those of the former. The whole leaf is shaped more like the point of a halbert, and those leaves which grow toward the upper part of the stalks, have very small indentures, so approach near to simple leaves without lobes. The flowers are also smaller, but of the same form, and the roots are of a shorter duration, so that I am inclined to believe it is a distinct species.

The eighth sort has some appearance of the seventh, so that many persons have supposed it was only an accidental variety of it, but there can be no doubt of its being a different species. The stalks of this rise upward of twenty feet high, and will continue two or three years; the leaves are larger, but of the same shape, and hairy; the tendrils of this sort are very long, as are also the foot-stalks of the flowers, which are smooth, not hairy as the former; the empalement of the flowers is netted, but not so long as in the former sort; the flowers are larger, and the rays are of a light blue colour; the fruit is much less and rounder than those of the other, and when ripe changes to a deep yellow colour.

The ninth sort was discovered by the late Dr. Houstoun growing naturally at La Vera Cruz; this a perennial plant. The stalks rise twenty feet high, dividing into many slender branches, which are covered with a soft hairy down. The leaves are shaped like the point of a halbert; they are three inches long, and one inch and a half at their base, of a light green, soft and silky to the touch, standing obliquely to the foot-stalks. The flowers come out at the wings of the leaves like the other species; these are not half so large as those

of the second sort, but are of the same form. The petals are white, and the rays or filaments are purple, with a mixture of yellow. The fruit of this is small, roundish, and yellow when ripe.

The tenth sort grows naturally in Jamaica, from whence the late Dr. Houstoun sent the seeds to England; this is a perennial plant. The stalks are slender, and rise to twenty feet high when they are supported, and divide into many weak branches; the leaves, flowers, and tendrils come out at each joint. The leaves are four inches long, and three broad, rounded at their base in form of a heart, but end at their points with two horns, which in some leaves are more acute than in others, several of them appearing as if they were cut a little hollow at the top, like the leaves of the Tulip-tree. They have three longitudinal veins, which join at the base of the leaf to the foot-stalk, but the two outer diverge toward the borders of the leaf in the middle, drawing inward again at the top. The leaves are of a deep green on their upper side, but are pale on their under, and stand upon short foot-stalks; the foot-stalks of the flowers are very slender, of a purplish colour, about an inch and a half long. The flowers are shaped like those of the other species, but when expanded are not more than an inch and a half diameter, of a soft red colour, and little scent. The fruit is small, oval, and when ripe, changes to a purple colour.

The eleventh sort was discovered by the late Mr. Robert Millar, growing naturally near Carthagena in New Spain. This hath slender striated stalks of a brownish red colour, dividing into many slender branches, which are garnished with leaves shaped like the wings of a bat when extended; they are about seven inches in length, measuring from the two extended points, which may rather be termed the breadth, for from the base to the top they are not more than two inches and a half. The foot-stalk is set half an inch from the base of the leaf, from which come out three ribs or veins; two of them extend each way to the two narrow points of the leaf, the other rises upright to the top, where is the greatest length of the leaf, if it may be so termed. The figure of this leaf is the most singular of any I have yet seen. The flowers come out at the joints of the stalk like the others, upon short slender foot-stalks; they are about three inches diameter when expanded. The petals and rays are white; the rays are twisted and slender, extending beyond the petals. The fruit of this I have not seen entire.

The twelfth sort was discovered by the late Dr. Houstoun, growing naturally at La Vera Cruz in New Spain. This hath slender angular stalks which rise twenty feet high, sending out many branches, which are garnished with moon-shaped leaves, and have two blunt lobes, spreading asunder each way, so as to have the appearance of a half moon. The flowers and tendrils come out from the same joints of the stalks. The flowers are of a pale colour and small, but shaped like those of the other sorts; these are succeeded by oval fruit of a purple colour, about the size of small oval Grapes.

The thirteenth sort has some resemblance of the twelfth, but the stalks are rounder and become ligneous. The leaves are almost as stiff as those of the Bay-tree, and are not so deeply divided as those of the former. The flowers stand upon long foot-stalks, which are horizontal; they are small, white, and shaped like those of the other sort. The fruit is oval, small, and of a purple colour, sitting close to the petals of the flowers, which are permanent. This was discovered by the late Dr. Houstoun growing naturally at Carthagena in New Spain.

The fourteenth sort grows naturally in most of the islands in the West-Indies; this is by Tournefort separated from this genus, and titled by him *Murucua*, which is the Brazilian name for this, and some of the other species. This hath slender climbing stalks, which are channelled, putting out tendrils at the joints, which fasten themselves about the neighbouring plants for support, and climb to the height of ten

or twelve feet; they are garnished with leaves which are cut into two lobes at their base, but at the top are only a little hollowed at a distance from each point, rising again in the middle opposite the foot-stalk. The base of the two lobes spread and meet, so that they appear as if they embraced the stalk; but when they are viewed near, they are found divided to the short crooked foot-stalk, which does scarcely appear. There are two purplish veins arising from the foot-stalk, which extend each way to the points of the lobes. The leaves are of a lucid green on their upper surface, but pale on their under; the tendrils, which come out with the leaves, are very long, tough, and of a purple colour. The flowers are produced toward the end of the branches, coming out by pairs on each side the branches; these have purple foot-stalks an inch and a half long, sustaining one flower at the top, whose empalement is composed of five purple leaves, which form a kind of tube, and within are five very narrow purple petals. The column in the center of the flower is of the same length as the petals, but the stamina are extended an inch above. When the flowers fade, the germen swells to an oval purple fruit, the size of the small red Gooseberry, inclosing a soft pulp, in which are lodged the seeds.

The fifteenth sort grows naturally in the West-Indies, where the inhabitants call it Granadilla; the fruit of this sort is commonly eaten there, being served up to their table in deserts. This hath a thick, climbing, herbaceous, triangular stalk, sending out slender tendrils at each joint, which fasten to the bushes and hedges for support, rising to the height of fifteen or twenty feet, garnished at each joint with one large, oval, heart-shaped leaf, six inches long, and four broad in the middle, indented at the base, where the short foot-stalk is fastened to the branches, round at the top, having an acute point. There are two large stipulæ or ears joined to the stalks, which encompass the foot-stalks of the flowers and leaves, as also the base of the tendril. The leaves are of a lively green and thin texture, having one strong nerve or midrib running longitudinally, from which arise several small veins, which diverge to the sides, and incurve again toward the top. The flowers stand upon pretty long foot-stalks, which have two small glandules in the middle; the cover of the flower is composed of three soft velvety leaves, of a pale red, with some stripes of a lively red colour; the petals of the flower are white, and the rays are blue. These flowers are large, so make a fine appearance during their continuance; but they are like the other species, of short duration, but there is a succession of flowers for some time on the same plants. After the flowers are past, the germen swells to a roundish fruit, the size of a large Apple, of a yellow colour when ripe, having a thicker rind than any of the other sorts, inclosing a sweetish pulp, in which are lodged many oblong flat seeds, of a brownish colour, a little rough to the touch.

The sixteenth sort grows naturally in the islands of the West-Indies; this hath climbing rough stalks, which put out clasps at every joint like the others, which fasten to the neighbouring trees and hedges for support, and rise upward of twenty feet high, sending out many side branches. The leaves are four or five inches long, and two broad, of a pretty thick consistence, and of a bright green on their upper side, but pale on their under. The flowers come out at the joints of the stalks, upon foot-stalks an inch and a half long; the buds of the flowers are as large as pigeons eggs before they begin to expand. The cover of the flower is composed of three large, oval, green leaves, which are indented on their edges, and hollowed like a spoon: within these is the empalement of the flower, which is composed of five oblong leaves, of a pale green on their outside, but whitish within; these are about an inch and a half long, and half an inch broad. The petals of the flower are white, and stand alternately with those of the empalement, but are not more than half their breadth, and are marked

with several small, brownish, red spots. The rays of the flower are of a Violet colour; the column in the center is yellowish, as is also the round germen at the top, but the three styles are of a purple colour. These flowers have an agreeable odour, and when they fade, the germen swells to the size of a pullet's egg, and nearly of the same shape, which turns yellow when ripe. The rind is soft and thick; the pulp has an agreeable acid flavour, which quenches thirst, abates the heat of the stomach, gives an appetite, and recruits the spirits, so is commonly given in fevers. The seeds are heart-shaped and brownish.

The seventeenth sort grows naturally in the Bahama Islands, from whence the late Mr. Catesby sent the seeds to England; this hath slender, climbing, three-cornered stalks, which send out tendrils at each joint, fastening themselves to any neighbouring support. The stalks climb to the height of twelve or fourteen feet, and are garnished with oblong oval leaves about two inches long, and one broad, of a light green, and entire. Their foot-stalks are slender, and an inch long, from which arise three longitudinal veins, one running through the middle of the leaf, the other two diverge to the sides, drawing toward each other again at the point. The flowers come out from the wings of the stalk, upon slender foot-stalks an inch long; the empalement of the flower is composed of five oblong, narrow, purplish leaves, and within are five narrower petals of the same colour, which turn backward after they have been some time expanded. The column in the middle of the flower is very long and slender, supporting a round germen, from whose base spread out five slender stamina, terminated by oblong hanging summits, and from the top of the germen arise three slender styles, which spread asunder, and are crowned by roundish summits. When the flowers fade, the germen swells to an oval fruit about the size of sparrow's egg, which changes to a purple colour when ripe, filled with oblong seeds inclosed in a soft pulp.

The nineteenth sort was discovered by the late Dr. Houstoun at La Vera Cruz in New Spain, where it grows naturally, from whence he sent the seeds in 1731 to England, which succeeded in several gardens. This hath slender climbing stalks, sending out many small branches, which climb to the height of twenty-five or thirty feet, when they meet with neighbouring support, to which they fasten themselves by tendrils. The stalks by age become ligneous toward the bottom; their joints are not far asunder. The leaves stand upon short slender foot-stalks; they are three inches and a half long, and two broad in the middle, rounded at their base, but terminate in a point at the top; they are smooth, entire, and of a lively green colour. The flowers come out from the wings of the leaves, standing upon long foot-stalks; the empalement of the flower is composed of five oblong leaves, green on their outside, but whitish within. The flower has five oblong white petals, situated alternately to the leaves of the empalement, which spread open; the rays are of a bluish purple colour, inclining at bottom to red; the column in the center is short and thick; the germen on the top is oval, and, after the flowers fade, swells to the size of a pullet's egg, and changes to a pale yellow when ripe, having many oblong seeds inclosed in a soft pulp. The flowers of this kind have an agreeable odour, but are of short duration, seldom continuing twenty hours open; but there is a succession of flowers on the plants from June to September, and sometimes the fruit will ripen here.

The twentieth sort has much the appearance of the fifteenth, both in stalk and leaves; but the stalks of this have four angles, whereas those of the fifteenth have but three: the leaves also of that are not hollowed at their base, but those of twentieth sort are almost heart-shaped; the flower of it is much larger, though very like it in colour, and the fruit is near twice as large, and of a very agreeable flavour.

This requires the same culture as the fifteenth, with which it will produce flowers, and often will ripen its fruit in England. By some persons this is confounded with the fifteenth sort, and passes for the Granadilla.

All these perennial sorts which are natives of the hot parts of America, require a stove to preserve them here, without which they will not thrive; for although some of the sorts will live in the open air during the warm months in summer, yet they make but little progress; nor will the plants produce many flowers, unless the pots in which they are planted are plunged into the tan-bed of the stove, and their branches are trained against an espalier. The best way to have them in perfection, is to make a border of earth on the back side of the tan-bed, which may be separated by planks to prevent the earth from mixing with the tan; and when the plants are strong enough, they should be turned out of the pots, and planted in this border; adjoining to which, should be a trellis erected to the top of the stove; against this the stalks of the plants must be trained, and as they advance they will form a hedge to hide the wall of the stove, and their leaves continuing green all the year, together with their flowers, which will be plentifully intermixed in summer, will have a very agreeable effect.

As there will be only a plank partition between the earth and the tan, so the earth will be kept warm by the tan-bed, which will be of great service to the roots of the plants. This border should not be less than two feet broad and three deep, which is the usual depth of the pit for tan; so that where these borders are intended, the pits should not be less than eight feet and a half, or nine feet and a half broad, that the bark-bed, exclusive of the border, may be six and a half or seven feet wide. If the border is fenced off with strong ship planks, they will last some years, especially if they are well painted over with a composition of melted pitch, brick-dust and oil, which will preserve them sound a long time; and the earth should be taken out carefully from between the roots of the plants, at least once a year, putting in fresh: with this management, I have seen these plants in great perfection. But where there has not been this convenience, I have turned the plants out of the pots, and planted them into the tan-bed when it was half rotten, into which they have rooted exceedingly, and have thriven for two or three years as well as could be desired; but when their roots extended to a great distance in the tan-bed, they have been injured by renewing of the bark; and when it has fermented pretty violently, the roots have been scalded, and the plants have been killed, so that the other method is more eligible.

These plants are propagated by seeds, which should be sown upon a good hot-bed in the spring, and when the plants are fit to remove, they should be each planted in a small pot filled with good kitchen-garden earth, and plunged into a bed of tanners bark, observing to shade them from the sun till they have taken new root; then they must be treated like other tender plants from the same countries. When they are too high to remain under the glasses of the hot-bed, they should be turned out of the pots and planted in the stove, in the manner before mentioned.

As these sorts do not often perfect their seeds here, so they may be propagated by laying down their branches, which, if done in April, they will put out roots by the middle of August, when they may be separated from the old plants, and either planted in pots to get strength, or into the border of the stove, where they are to remain.

Some of these sorts may also be propagated by cuttings; these should be planted into pots about the middle or latter end of March, and plunged into a moderate hot-bed, observing to screen them from the sun, and refresh them with water gently, as often as the earth may require it; and in about two months or ten weeks, they will put out roots, and may then be treated as the seedling plants.

PASSION-FLOWER. See PASSIFLORA.

PASTINACA. Tourn. Inst. R. H. 319. tab. 170. Lin. Gen. Plant. 324. [of Pastus, Lat. fed; because it is a plant whose root is edible.] Parsnep; in French, *Panaïs*.

The CHARACTERS are,

It hath an umbellated flower; the principal umbel is composed of many smaller, and these are likewise composed of several rays. They have no involucre, and the empalement is scarce visible; the umbel is uniform. The flowers have five spear-shaped incurved petals, and five hair-like stamina, terminated by roundish summits. The germen is situated under the flower, supporting two reflexed styles, crowned by obtuse stigmas. The germen afterward becomes an elliptical, plain, compressed fruit, dividing into two parts, having two bordered elliptical seeds.

This genus of plants is ranged in the second section of Linnæus's fifth class, which contains those plants whose flowers have five stamina and two styles.

The SPECIES are,

1. PASTINACA (*Sylvestris*) foliis simpliciter pinnatis hirsutis. Parsnep with single, winged, hairy leaves. Pastinaca sylvestris latifolia. C. B. P. 155. Broad-leaved Wild Parsnep.
2. PASTINACA (*Sativa*) foliis simpliciter pinnatis glabris. Parsnep with single winged smooth leaves. Pastinaca sativa, latifolia. C. B. P. 155. Broad-leaved Garden Parsnep.
3. PASTINACA (*Opopanax*) foliis decompositis pinnatis. Hort. Cliff. 105. Parsnep with decomposed winged leaves. Pastinaca sylvestris altissima. Tourn. Inst. 319. Tallest wild Parsnep, by Caspar Bauhin titled, *Panax Costivum*. Pin. 156.

The first sort grows naturally on the side of banks, and on dry land, in many parts of England. This is a biennial plant, the first year shooting out leaves which spread on the surface of the ground; these are singly winged, and the lobes are irregularly cut; the leaves are hairy. The following year the stalks rise four or five feet high, which are channelled, hairy, and garnished with winged leaves like those at the bottom, but smaller; the stalk branches out toward the top, each branch being terminated by a large umbel of yellow flowers; these are succeeded by compressed fruit, having two flat bordered seeds. The plant flowers in June, and the seeds ripen in August.

The root and seed of this sort is sometimes used in medicine, but it is seldom cultivated in gardens, the markets being supplied from the fields; yet the druggists commonly sell the seeds of the garden kind for it, which they may purchase at an easy price when it is too old to grow, but then the seeds can have no virtue left.

The second sort hath smooth leaves, of a light or yellowish green colour, in which this differs from the former; the stalks also rise higher, and are deeper channelled; the foot-stalks of the umbels are much longer, and the flowers are of a deeper yellow colour. These two sorts have been thought only varieties, the Garden Parsnep they have supposed to differ from the wild only by culture; but I have cultivated both many years, and have never found that either of the sorts have varied; the seeds of each having constantly produced the same sort as they were taken from, so that I am certain they are distinct species.

This sort is cultivated in kitchen-gardens, the roots of which are large, sweet, and accounted very nourishing. They are propagated by seeds, which should be sown in February or March, in a rich mellow soil, which must be well dug, that their roots may run downward, the greatest excellency being the length and bigness of the roots. These may be sown alone, or with Carrots, as is practised by the kitchen-gardeners near London; some of whom also mix Leeks, Onions, and Lettuce, with their Parsneps; but this I think very wrong, for it is not possible, that so many different sorts can thrive well together, except they are allowed a considerable distance; and if so, it will be equally the same to sow the different sorts separate. However, Carrots and Parsneps may be sown together very well, especially where the Carrots are designed

to be drawn off very young ; because the Parsneps generally spread most towards the latter end of the summer, which is after the Carrots are gone, so that there may be a double crop upon the same ground.

When the plants are come up, you should hoe them out, leaving them about ten inches or a foot asunder ; observing at the same time to cut up all the weeds, which, if permitted to grow, would soon overbear the plants and choke them. This must be repeated three or four times in the spring, according as you find the weeds grow ; but in the latter part of summer, when the plants are so strong as to cover the ground, they will prevent the growth of weeds, so that after that season they will require no farther care.

When the leaves begin to decay, the roots may be dug up for use, before which time they are seldom well tasted ; nor are they good for much in the spring, after they are shot out again ; so that those who would preserve these roots for spring use, should dig them up in the beginning of February, and bury them in sand, in a dry place, where they will remain good until the middle of April, or later.

If you intend to save the seeds of this plant, you should make choice of some of the longest, straightest, and largest roots, which should be planted about two feet asunder, in some place where they may be defended from the strong south and west winds ; for the stems of these plants commonly grow to a great height, and are very subject to be broken by strong winds, if exposed thereto ; they should be constantly kept clear from weeds, and if the season should prove very dry, if you give them some water twice a week, it will cause them to produce a greater quantity of seeds, which will be much stronger than if they were wholly neglected. Toward the latter end of August or the beginning of September, the seeds will be ripe ; at which time you should carefully cut off the umbels, and spread them upon a coarse cloth for two or three days to dry ; after which, the seeds should be beaten off, and put up for use ; but you must never trust to these seeds after they are a year old, for they will seldom grow beyond that age.

The leaves of the Garden Parsnep are dangerous to handle, especially in a morning, while the dew remains upon them ; at which time, if they are handled by persons who have a soft skin, it will raise it in blisters. I have known some gardeners, when they have been drawing up Carrots from among Parsneps in a morning, when their leaves were wet with dew, they have drawn the sleeves of their shirts up to their shoulders, to prevent their being wet ; by doing of which they have had their arms, so far as they were bare, covered over with large blisters ; and these were full of a scalding liquor, which has proved very troublesome for several days.

The third sort rises with a green rough stalk seven or eight feet high, garnished with large, compounded, winged leaves, which are very rough to the touch, and of a dark green colour ; the juice is very yellow, which flows out where either the leaf or stalk is broken ; the stalks are divided upward into many horizontal branches, each being terminated by a large umbel of yellow flowers. These appear in July, and are succeeded by plain seeds which are bordered, and a little convex in the middle, which ripen in the autumn. The Opapanax of the shops is thought to be the concrete juice of this plant.

PASTURE.

Pasture ground is of two sorts : the one is low meadow land, which is often overflowed, and the other is upland, which lies high and dry. The first of these will produce a much greater quantity of hay than the latter, and will not require manuring or dressing so often ; but then the hay produced on the upland is much preferable to the other, as is also the meat which is fed in the upland more valued than that which is fatted in rich meadows ; though the latter will make the fatter and larger cattle, as is seen by those which are brought from the low rich lands in Lincolnshire. But where people are nice in their meat, they

will give a much larger price for such as hath been fed on the downs, or in short upland Pasture, than for the other, which is much larger. Besides this, dry Pastures have an advantage over the meadows, that they may be fed all the winter, and are not so subject to poach in wet weather ; nor will there be so many bad weeds produced, which are great advantages, and do, in a great measure, recompense for the smallness of the crop.

I have already mentioned the advantages of meadow land, or such as is capable of being overflowed with water, and given directions for draining and improving low Pasture land, under the article of LAND ; therefore shall not repeat what is there said, but I shall just mention some method for improving of upland Pasture.

The first improvement of upland Pasture is, by fencing it, and dividing it into small fields of four, five, six, eight, or ten acres each, planting timber trees in the hedge rows, which will screen the Grass from the drying pinching winds of March, which prevents the Grass from growing in large open lands ; so that if April proves a cold dry month, the land produces very little hay ; whereas in the sheltered fields the Grass will begin to grow early in March, and will soon after cover the ground, and prevent the sun from parching the roots of the Grass, whereby it will keep growing, so as to afford a tolerable crop, if the spring should prove dry. But in fencing of land, it must be observed (as was before directed) not to make the inclosures too small, especially where the hedge rows are planted with trees ; because when the trees are advanced to a considerable height, they will spread over the land ; and, where they are close, will render the Grass sour ; so that instead of being an advantage, it will greatly injure the Pasture.

The next improvement of upland Pastures is, to make the turf good, where, either from the badness of the soil, or want of proper care, the Grass hath been destroyed by Rushes, bushes, or mole-hills. Where the surface of the land is clayey and cold, it may be improved by paring it off, and burning it in the manner before directed under the article of LAND ; but if it is a hot sandy land, then chalk, lime, marle, or clay, are very proper manures to lay upon it ; but this should be laid in pretty good quantities, otherwise it will be of little service to the land.

If the ground is over-run with bushes or Rushes, it will be of great advantage to the land, to grub them up toward the latter part of the summer, and after they are dried to burn them, and spread the ashes over the ground just before the autumnal rains ; at which time the surface of the land should be levelled, and sown with Grass-seed, which, if done early in the autumn, will come up in a short time, and make good Grass the following spring. So also, where the land is full of mole-hills, these should be pared off, and either burnt for the ashes, or spread immediately on the ground, when they are pared off, observing to sow the bare patches with Grass-seed, just as the autumnal rains begin.

There are some Pasture lands which are full of ant-hills, which are not only disagreeable to the sight, but where they are in any quantity, the Grass cannot be mowed ; therefore the turf which grows over them should be divided with an instrument into three parts, and pared off each way ; then the middle or core of the hills should be dug out and spread over the ground, leaving the holes open all the winter to destroy the ants, and in the spring the turf may be laid down again, and after the roots of the Grass are settled again in the ground, it should be rolled to settle the surface, and make it even. If this is properly managed, it will be a great improvement to such land.

Where the land has been thus managed, it will be of great service to roll the turf in the months of February and March, with a heavy wood roller, always observing to do it in moist weather, that the roll may make an impression : this will render the surface level, and make it much easier to mow the Grass, than when

when the ground lies in hills; and will also cause the turf to thicken, so as to have what the people usually term a good bottom. The Grass likewise will be the sweeter for this husbandry, and it will be a great help to destroy bad weeds.

Another improvement of upland Pastures is the feeding them every other year; for where this is not practised, the land must be manured at least every third year; and where a farmer hath much arable land in his possession, he will not care to part with his manure to the Pasture. Therefore every farmer should endeavour to proportion his Pasture to his arable land, especially where manure is scarce, otherways he will soon find his error; for the Pasture is the foundation of all the profit, which may arise from the arable land. Whenever the upland Pastures are mended by manure, there should be a regard had to the nature of the soil, and a proper sort of manure applied: as for instance, all hot sandy lands should have a cool manure; neats dung and swines dung are very proper for such lands, as also marle and clay; but for cold lands, horse dung, ashes, or sand, and other warm manures, are proper. And when these are applied, it should be done in autumn, before the rains have soaked the ground, and rendered it too soft to cart on; and it should be carefully spread, breaking all the clods as small as possible, and early in the spring harrowed with bushes, to let it down to the roots of the Grass. When the manure is laid on at this season, the rains in winter will wash down the salts, so that the following spring the Grass will receive the advantage of it.

There should also be great care had to the destroying of weeds in the Pasture, every spring and autumn; for where this is not practised, the weeds will ripen their seeds, which will spread over the ground, and thereby fill it with such a crop of weeds as will soon overbear the Grass, and render it very weak, if not destroy it; and it will be very difficult to root them out, after they have gotten such possession; especially Ragwort, Hawkweed, Dandelion, and such other weeds as have down adhering to their seeds.

These upland Pastures seldom degenerate the Grass which is sown on them, if the land is tolerably good; whereas the low meadows, which are overflowed in winter, in a few years turn to a harsh rushy Grass, but the upland will continue a fine sweet Grass for many years without renewing.

There is no part of husbandry, of which the farmers are in general more ignorant, than that of the Pasture; most of them suppose, that when the old Pasture is ploughed up, it can never be brought to have a good sward again; so their common method of managing their land after ploughing, and getting two or three crops of Corn is, to sow with their crop of Barley, some Grass-seeds, as they call them; that is, either the red Clover, which they intend to stand two years after the Corn is taken off the ground, or Ryegrass mixed with Trefoil; but as all these are at most but biennial plants, whose roots decay soon after their seeds are perfected, so the ground having no crop upon it, is again ploughed for Corn; and this is the constant round which the lands are employed in, by the better sort of farmers; for I never have met with one of them, who had the least notion of laying down their land to Grass for any longer continuance; therefore the seeds which they usually sow, are the best adapted for this purpose.

But whatever may have been the practice of these people, I hope to prove, that it is possible to lay down land, which has been in tillage, with Grass, in such manner as that the sward shall be as good, if not better, than any natural Grass, and of as long duration. But this is never to be expected, in the common method of sowing a crop of Corn with the Grass-seeds; for wherever this hath been practised, if the Corn has succeeded well, the Grass has been very poor and weak; so that if the land has not been very good, the Grass has scarcely been worth standing; for the following year it has produced but little hay, and

the year after the crop is worth little, either to mow or feed. Nor can it be expected it should be otherwise, for the ground cannot nourish two crops; and if there were no deficiency in the land, yet the Corn being the first, and most vigorous of growth, will keep the Grass from making any considerable progress; so that the plants will be extremely weak and but very thin, many of them which came up in the spring being destroyed by the Corn; for wherever there are roots of Corn, it cannot be expected there should be any Grass. Therefore the Grass must be thin, and, if the land is not in good heart to supply the Grass with nourishment, that the roots may branch out after the Corn is gone, there cannot be any considerable crop of Clover; and as these roots are biennial, many of the strongest plants will perish soon after they are cut; and the weak plants, which had made but little progress before, will be the principal part of the crop for the succeeding year, which is many times not worth standing.

Therefore, when ground is laid down for Grass, there should be no crop of any kind sown with the seeds; and the land should be well ploughed, and cleaned from weeds; otherwise the weeds will come up the first, and grow so strong, as to overbear the Grass, and if they are not pulled up, will entirely spoil it. The best season to sow the Grass seeds upon dry land is about the middle of August, if there is an appearance of rain; for the ground being then warm, if there happen some good showers of rain after the seed is sown, the Grass will soon make its appearance, and get sufficient rooting in the ground before winter, so will not be in danger of having the roots turned out of the ground by the frost, especially if the ground is well rolled before the frost comes on, which will press it down, and fix the earth close to the roots. Where this hath not been practised, the frost has often loosened the ground so much, as to let in the air to the roots of the Grass, and done it great damage; and this has been brought as an objection to the autumnal sowing of Grass; but it will be found to have no weight, if the above direction is practised; nor is there any hazard in sowing the Grass at this season, but that of dry weather after the seeds are sown; for if the Grass comes up well, and the ground is well rolled in the middle or end of October, and repeated the beginning of March, the sward will be closely joined at bottom, and a good crop of hay may be expected the same summer. In very open, exposed, cold lands, it is proper to sow the seeds earlier than is here mentioned, that the Grass may have time to get good rooting, before the cold season comes on to stop its growth; for in such situations, vegetation is over early in the autumn, so the Grass being weak, may be destroyed by frost: but if the seeds are sown in the beginning of August, and a few showers follow soon after to bring up the Grass, it will succeed much better than any which is sown in the spring, as I have several years experienced, on some places as much exposed as most in England. But where the ground cannot be prepared for sowing at that season, it may be performed the middle or latter end of March, according to the season's being early or late; for in backward springs and in cold land, I have often sowed the Grass in the middle of April with success; but there is danger in sowing late of dry weather, and especially if the land is light and dry; for I have seen many times the whole surface of the ground removed by strong winds at that season, so that the seeds have been driven in heaps to one side of the field. Therefore whenever the seeds are sown late in the spring, it will be proper to roll the ground well soon after the seeds are sown, to settle the surface, and prevent its being removed.

The sorts of seeds which are the best for this purpose, are the best sort of upland hay-seeds, taken from the cleanest Pastures, where there are no bad weeds; if this seed is sifted to clean it from rubbish, three, or at most four bushels, will be sufficient to sow an acre of land. The other sort is the *Trifolium pratense*

pratense album, which is commonly known by the names of White Dutch Clover, or White Honey-suckle Grass. Eight pounds of this seed will be enough for one acre of land. The Grass-seed should be sown first, and then the Dutch Clover-seed may be afterward sown; but they should not be mixed together, because the Clover-seeds being the heaviest, will fall to the bottom, and consequently the ground will be unequally sown with them.

After the seeds are sown, the ground should be lightly harrowed to bury the seeds; but this should be performed with a short-toothed harrow, otherwise the seeds will be buried too deep. Two or three days after sowing, if the surface of the ground is dry, it should be rolled with a Barley roller to break the clods and smooth the ground, which will settle it, and prevent the seeds from being removed by the wind.

When the seeds are come up, if the land should produce many weeds, these should be drawn out before they grow so tall as to overbear the Grass; for where this has been neglected, the weeds have taken such possession of the ground, as to keep down the Grass and starve it; and when these weeds have been suffered to remain until they have shed their seeds, the land has been so plentifully stocked with them, as entirely to destroy the Grass; therefore it is one of the principal parts of husbandry, never to suffer weeds to grow on the land.

If the ground is rolled two or three times at proper distances after the Grass is up, it will press down the Grass, and cause it to make a thicker bottom; for as the Dutch Clover will put out roots from every joint of the branches which are near the ground, so by pressing down the stalks, the roots will mat so closely together, as to form a sward so thick as to cover the whole surface of the ground, and form a green carpet, which will better resist the drought. For if we do but examine the common Pastures in summer (in most of which there are patches of this White Honey-suckle Grass growing naturally) we shall find these patches to be the only verdure remaining in the fields. And this the farmers in general acknowledge, is the sweetest feed for all sorts of cattle, yet never had any notion of propagating it by seeds till of late years. Nor has this been long practised in England; for till within a few years, that some curious persons imported the seed from Brabant, where it had been long cultivated, there was not any of the seeds saved in England; though now there are several persons who save the seeds here, which succeed full as well as any of the foreign seeds which are imported.

As this White Clover is an abiding plant, so it is certainly the very best sort to sow where Pastures are laid down to remain; for as the hay-seeds which are taken from the best Pastures, will be composed of various sorts of Grass, some of which may be but annual and others biennial, so when those go off, there will be many and large patches of ground left bare and naked, if there is not a sufficient quantity of the White Clover to spread over and cover the land. Therefore a good sward can never be expected where this is not sown; for in most of the natural Pastures, we find this plant makes no small share of the sward; and it is equally good for wet and dry land, growing naturally upon gravel and clay in most parts of England; which is a plain indication how easily this plant may be cultivated to great advantage, in most sorts of land throughout this kingdom.

Therefore the true cause why the land which is in tillage is not brought to a good turf again, in the usual method of husbandry is, from the farmers not distinguishing which Grasses are annual, from those which are perennial; for if annual or biennial Grasses are sown, these will of course soon decay; so that unless where some of their seeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. Therefore this, together with the covetous method of laying down the ground with a crop of Corn, has occasioned the general failure of increasing the Pasture in many parts of England,

where it is now much more valuable than any arable land.

After the ground has been sown in the manner before directed, and brought to a good sward, the way to preserve it good is, by constantly rolling the ground with a heavy roller, every spring and autumn, as hath been before directed. This piece of husbandry is rarely practised by farmers, but those who do, find their account in it, for it is of great benefit to the Grass. Another thing should also be carefully performed, which is, to cut up Docks, Dandelion, Knapweed, and all such bad weeds, by their roots, every spring and autumn; this will increase the quantity of good Grass, and preserve the Pastures in beauty. Dressing of these Pastures every third year, is also a good piece of husbandry, for otherwise it cannot be expected the ground should continue to produce good crops. Besides this, it will be necessary to change the seasons of mowing, and not to mow the same ground every year, but to mow one season, and feed the next; for where the ground is every year mown, it must be constantly dressed, as most of the Grass grounds near London, otherwise the ground will be soon exhausted.

Of late years there has been an emulation, especially among gentlemen, to improve their Pastures, by sowing several sorts of Grass-seeds; and there have been some persons of little skill in these matters, who have imposed on many ignorant people, by selling them seeds of some foreign Grass, recommending them for some particular quality, but when tried have proved of little worth, whereby they have lost a season or two, and have had their work to begin again. Therefore I would advise every person, not to trust too much upon the faith of such practitioners, who, upon slight experiments, have ventured to recommend without judgment; for of all the sorts of Grass-seeds which have been brought from America (of which I have, at various times, sown more than a hundred different species) I have found none equal to the common Poa Grass, which grows naturally in England, either for duration or verdure; therefore that, and about six or seven other sorts, are the best worth cultivating; but the trouble of collecting these in quantity is so great, as to deter most people from attempting it; and in the purchasing of hay-seeds, there is generally more seeds of weeds than Grass, which will fill the ground; therefore for some years past, I have recommended and sown only the White Dutch Clover-seeds, and have waited for the natural Grass coming up amongst it, and have generally succeeded better this way than by sowing hay-seed with it; for if the Pasture is duly weeded, rolled, and dressed, all bad weeds may be destroyed, and a fine durable turf obtained: whereas the Burnet, and many other plants, which have been extolled as a good winter pabulum, are of short duration, so very improper for improving land; nor are there two better plants yet known for the purpose of fodder, than the Lucern and Saint-foin; for where these are properly sown upon right soils and duly cultivated, they will produce a much greater quantity of food, than can be procured from the same quantity of land, sown with any other abiding plant: therefore I wish those who are curious to have much fodder for their cattle, to apply themselves to the culture of these, and not engage in uncertain experiments.

P A V I A. Boerh. Ind. alt. 2. p. 260. Esculus. Lin. Gen. Plant. 420. The scarlet, flowering, Horse Chestnut.

The CHARACTERS are,

The flower has a small bellied empalement of one leaf, indented in five parts at the top. The flower has five roundish petals, waved and plaited on their borders, and narrow at their base, where they are inserted in the empalement. It hath eight stamina which are declined, and as long as the petals, terminated by rising summits; and a roundish germen sitting upon an awl-shaped style, crowned by an acuminate stigma. The germen afterward becomes an oval, Pear-shaped, leathery capsule with three cells.

in which is sometimes one, and at others two, almost globular seeds.

This genus of plants should be ranged in the first section of Linnæus's eighth class, which includes those plants whose flowers have eight stamina and one style; but he has joined this to the Horse Chestnut, under the title *Esculus*, and places it in his seventh class; but as the flowers of this have eight stamina, and those of the Horse Chestnut but seven; and the capsule of this is smooth, and that of the Horse Chestnut prickly, so they may be very well separated.

There is but one SPECIES of this genus, viz.

- PAULLINIA (*Octandria*.) Boerh. Ind. alt. 2. p. 260. *The scarlet Horse Chestnut*. Dr. Linnæus titles it, *Esculus floribus octandris*. Sp. Plant. 344. *Esculus with flowers having eight stamina*.

This plant grows naturally in Carolina and the Brazils; from the first the seeds were brought to England, where the plants have been of late years much cultivated in the gardens. In Carolina it is but of humble growth, seldom rising more than eight or ten feet high; the stalk is pretty thick and woody, sending out several branches, which spread out on every side, which are garnished with hand-shaped leaves, composed of five or six spear-shaped lobes, which unite at their base where they join the foot-stalk; they are of a light green, having a rough surface, and are sawed on their edges; these have long foot-stalks, and stand opposite on the branches. The flowers are produced in loose spikes at the end of the branches, standing upon long naked foot-stalks, which sustain five or six tubulous flowers spread open at the top, where the petals are irregular in size and length, having an appearance of a lip flower; they are of a bright red colour, and have eight stamina the length of the petals. When the flowers fade, the germen swells to a Pear-shaped fruit, with a thick russet cover having three cells, one of which, and sometimes two, are pregnant with globular seeds. It flowers in July, and the seeds sometimes ripen here in autumn. It may be propagated by sowing the seeds in the spring, upon a moderate hot-bed covered with light sandy earth; and when the plants come up, they should be carefully cleared from weeds, but they must not be transplanted until the year following. But as these seedling plants are tender while they are young, so they should be covered with mats the following winter; and this should be carefully performed in autumn, when the early frosts begin; for as the tops of these young plants are very tender, so a small frost will pinch them; and when the tops are killed, they generally decay to the ground; and when this happens, they seldom make good plants after. Therefore this should be constantly observed for two or three years at least, by which time the plants will have gotten strength enough to resist the frost, when they should be removed just before they begin to shoot, and placed either in a nursery to be trained up, or otherwise where they are to remain; observing, if the season proves dry, to water them until they have taken root, as also to lay some mulch upon the surface of the ground, to prevent the sun and wind from drying it too fast; and as the plants advance, the lateral branches should be pruned off, in order to reduce them to regular stems.

You must also observe to dig the ground about their roots every spring, that it may be loose, to admit the fibres of the roots, which, while young, are too tender to penetrate the ground if it be very hard.

With this management the plants will greatly advance, and in four or five years will produce flowers and often fruits, which in warm seasons ripen enough to grow, so that the plants may be multiplied therefrom very fast.

This tree may also be propagated by budding or grafting it upon the common Horse Chestnut, which is the common method practised by the nurserymen; but the trees thus raised, seldom make a good appearance long, for the common Horse Chestnut will be more than twice the size of the other, and fre-

quently put out shoots below the graft, and sometimes the grafts are blown out of the stocks, after ten years growth; but these stocks render the trees hardy, and of a larger growth.

- PAULLINIA. Lin. Gen. Plant. 446. Serjana. Plum. Nov. Gen. 34. tab. 35. Cururu. Plum. Nov. Gen. 34. tab. 35.

The CHARACTERS are,

The flower has a spreading permanent empalement, composed of four small oval leaves. It hath four oblong oval petals twice the size of the empalement, and eight short stamina, terminated by small summits, with a turbinate germen, having three obtuse corners, supporting three short slender styles, crowned by spreading stigmas. The germen afterward turns to a large three-cornered capsule with three cells, each containing one almost oval seed. The capsule of Plumier's Serjana has the seeds fastened to the base, and that of Cururu has the seeds growing to the top. This genus of plants is ranged in the third section of Linnæus's eighth class, which includes those plants whose flowers have eight stamina and three styles.

The SPECIES are,

1. PAULLINIA (*Serjana*) foliis ternatis, petiolis teretibus, foliolis ovato-oblongis. Lin. Sp. Plant. 365. *Three-leaved Paullinia with taper foot-stalks, and oblong oval lobes to the leaves*. Serjana scandens, triphylla & racemosa. Plum. Nov. Gen. 34. *Climbing branching Serjana with three leaves*.
2. PAULLINIA (*Mexicana*) foliis biternatis, petiolis marginatis, foliolis ovatis integris. Lin. Sp. Plant. 366. *Paullinia with nine lobes in each leaf, bordered foot-stalks, having oval entire lobes*. Serjana scandens enneaphylla & racemosa. Plum. Nov. Gen. 34. *Climbing branching Serjana with nine leaves*.
3. PAULLINIA (*Cururu*) foliis ternatis, foliolis cuneiformibus, obtusis subdentatis. Lin. Sp. Plant. 365. *Three-leaved Paullinia with trifoliate leaves having wedge-shaped lobes, which are obtuse and somewhat indented*. Cururu scandens triphylla. Plum. Nov. Gen. 34. *Climbing three-leaved Cururu*.
4. PAULLINIA (*Curassavica*) foliis biternatis, foliolis ovatis. Lin. Sp. Plant. 366. *Paullinia with double trifoliate leaves, having oval sinuated lobes*. Cururu scandens enneaphylla, fructu racemoso rubro. Plum. Nov. Gen. 34. *Climbing nine-leaved Cururu, with a red branching fruit*.
5. PAULLINIA (*Pinnata*) foliis pinnatis, foliolis incisis, petiolis marginatis. Hort. Cliff. 52. *Paullinia with winged leaves whose lobes are cut, and bordered foot-stalks*. Cururu scandens pentaphylla. Plum. Nov. Gen. 37. *Climbing five-leaved Cururu*.
6. PAULLINIA (*Tomentosa*) foliis pinnatis tomentosis, foliolis ovatis incisis, petiolis marginatis. *Paullinia with winged woolly leaves whose lobes are oval, cut on their edges, and bordered foot-stalks*. Cururu scandens, pentaphylla & villosa, fructu racemoso rubro. Houst. MSS. *Climbing Cururu with five leaves which are hairy, and a red fruit growing in long bunches*.

These plants all grow naturally in the West-Indies, where there are several other species which are not here enumerated. They have climbing stalks with tendrils at each joint, by which they fasten themselves to the neighbouring trees, and rise to the height of thirty or forty feet, garnished at each joint with one leaf, which in some species is composed of three lobes like Trefoil, in others of five lobes; some have nine, and others have many lobes. These are in some species entire, in others they are indented at the point, and some are cut on their edges; in some species their surface is smooth, in others they are woolly. The flowers come out in long bunches like those of Currants; they are small and white, so make no figure; these are succeeded by three-cornered capsules having three cells, which in the Cururu of Plumier, contain roundish seeds; but those of the Serjana have winged seeds like those of the Maple reversed, being fastened at the extremity of the wing to the capsule, the seed hanging downward.

As these plants are so tender as not to live through the winter in England, unless they are placed in a warm stove,

P E G

stove, and requiring a large share of room, they are seldom propagated in Europe, unless in botanic gardens for the sake of variety, for their flowers have very little beauty to recommend them.

They are propagated by seeds, which must be obtained from the countries where they naturally grow, for they do not produce seeds in England. These should be sown in small pots, filled with light earth, as soon as they arrive, and the pots should be plunged into a moderate hot-bed of tanners bark. If these seeds arrive in the autumn, the pots should be plunged into the bark-bed in the stove, and then there will be a probability of the plants coming up the following spring; but those seeds which do not arrive here till spring, will not come up the same year, so the pots in which they are sown, should be plunged into a moderate hot-bed under a frame, where they may be continued all the summer, but in the autumn they should be removed into the stove, where they should remain during the winter, and as the earth in the pots will be dry, so they should be now and then watered, but it should be given sparingly. The following spring the pots should be removed out of the stove and plunged into a new hot-bed under a frame, which will bring up the plants in about six weeks if the seeds are good. When the plants are fit to remove, they should be each planted in a small pot filled with light earth, and plunged into a hot-bed of tanners bark, observing to shade them every day from the sun till they have taken new root, after which they should have free air admitted to them daily, in proportion to the warmth of the season. In the autumn they must be removed into the bark-stove, where they should constantly remain, and must be treated in the same way as other tender plants.

PEACH. See **PERSICA**.

PEAR. See **PYRUS**.

PEAS. See **PISUM**.

PEASEVERLASTING. See **LATHYRUS**.

PEDICLE is that part of a stalk which immediately sustains the leaf, a flower, or a fruit, and is commonly called a foot-stalk.

PEDICULARIS, Rattle, Cocks-comb, or Lousewort.

There are four different kinds of this plant, which grow wild in pastures in several parts of England, and in some low meadows are very troublesome to the pastures, especially one sort with yellow flowers, which rises to be a foot high, or more, and is often in such plenty, as to be the most predominant plant; but this is very bad food for cattle, and when it is mowed with the Grass for hay, renders it of little value. The seeds of this plant are generally ripe by the time the Grass is mowed, so that whenever persons take Grass-seed for sowing, they should be very careful that none of this seed is mixed with it. As these plants are never cultivated, I shall not trouble the reader with their several varieties.

PEGANUM. Lin. Gen. Plant. 530. Harmala. Tourn. Inst. R. H. 257. tab. 133. Wild Assyrian Rue.

The **CHARACTERS** are,

The flower has a permanent empalement, composed of five narrow erect leaves the length of the petal. It has five oblong oval petals which spread open, and fifteen awl-shaped stamina about half the length of the petals, whose bases spread into a nectarium under the germen, and are terminated by erect oblong summits. It has a three-cornered roundish germen, elevated at the base of the flower, with a three-cornered slender style the length of the summits, and three stigmas which are longer than the style. The germen afterward becomes a roundish three-cornered capsule, having three cells, filled with oval acute-pointed seeds.

This genus of plants is ranged in the first section of Linnaeus's eleventh class, which includes those plants whose flowers have from eleven to nineteen stamina, and one style.

We have but one **SPECIES** in the English gardens at present, viz.

PEGANUM (*Harmala*) foliis multifidis. Hort. Upsal. 144.

P E N

Peganum with many-pointed leaves. Harmala. Doq. Pempt. 121. Ruta sylvestris, flore magno albo. C.B.P. 336. *Wild Rue with a large white flower.*

This plant grows naturally in Spain and Syria; it has a root as large as a man's little finger, which by age becomes woody. The stalks decay every autumn, and new ones arise in the spring; these grow about a foot long, and divide into several small branches, which are garnished with oblong thick leaves cut into several narrow segments; they are of a dark green, and of a gummy bitterish taste. The flowers are produced at the end of the branches, sitting close between the leaves; they are composed of five roundish white petals, which open like a Rose, having fifteen awl-shaped stamina, terminated by oblong, yellow, erect summits. In the center is situated a roundish three-cornered germen, having a three-cornered style the length of the stamina, with three stigmas which are longer than the style. The germen afterward becomes a roundish three-cornered capsule, having three cells, which contain several oval acute-pointed seeds. It flowers in July, and in warm summers the seeds will ripen here in the autumn.

It is propagated by seeds, which should be sown thinly on a bed of light earth the beginning of April, and when the plants come up, they must be constantly kept clean from weeds, which is all the culture they will require till the end of October, or the beginning of November, when their stalks decay. At which time, if the bed is covered with tanners bark, ashes, saw-dust, or such like covering to keep out the frost, it will be a secure way to preserve the roots, which when young are somewhat tender. The following March the roots may be taken up, and transplanted into a warm situation and a dry soil, where they will continue several years. This is sometimes used in medicine.

PELECINUS. See **BISERRULA**.

PELLITORY OF SPAIN. See **ANTHEMIS**.

PELLITORY OF THE WALL. See **PARIETARIA**.

PELTARIA. Jacq. Vind. 260. Lin. Gen. Plant. 806. Mountain Treacle Mustard.

The **CHARACTERS** are,

The empalement of the flower is composed of four small, concave, coloured leaves which fall off; the flower has four petals placed in form of a cross, whose necks are shorter than the empalement, and six awl-shaped stamina, two of which are shorter than the empalement, terminated by single summits, with a roundish germen supporting a short style, crowned by an obtuse stigma. The germen afterward becomes a roundish compressed pod with one cell, containing one roundish seed.

This genus of plants is ranged in the first section of Linnaeus's fifteenth class, intitled Tetrastemonia Sili-culosa, the flower having four long and two short stamina, and the seeds being included in short pods.

We have but one **SPECIES** of this genus, viz.

PELTARIA (*Alliacea*.) Jacq. Vind. 260. Lin. Sp. Plant. 910. *Peltaria or Treacle Mustard.* Thlaspi montanum, glast folio majus. C. B. P. 106. *Mountain Treacle Mustard with a Wood leaf.*

This plant grows naturally upon the mountains in Austria and Istria; it is a biennial, so generally dies soon after the seeds are perfected. It rises with an upright branching stalk about a foot high, garnished with heart-shaped smooth leaves, which embrace the stalks with their base; the stalks are terminated by clusters of white flowers growing in form of umbels, each flower having four petals placed in form of a cross; these are succeeded by roundish compressed pods, each containing one seed of the same form. The plant flowers in May, and the seeds ripen in July. This is easily propagated by seeds, which may be sown in small patches in the borders of the flower-garden the beginning of April, and when the plants are up, there should be four or five left in each patch; the others should be pulled out, to give these room to grow; after this, they will require no other culture but to keep them clean from weeds.

P E N D U

PENDULOUS HEADS OF FLOWERS are such as hang downward.

PENNATED. A pennated leaf (called in Latin *Folium Pennatum*) is a compound leaf, divided into several parts (each of which is called a lobe,) placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is said to be unequally pennated, and equally pennated, when it is not terminated by an odd lobe. When the lobes are all nearly of the same form and bigness, it is called an uniform pennated leaf; when they are not so, it is said to be difform. Examples of pennated leaves are the Ash, Walnut, &c.

PENNY-ROYAL. See **PULEGIUM**.

PENTAPETALOUS FLOWERS are such as have five leaves.

PENTAPETES. Lin. Gen. Plant 757. Alcea. Raii Supp. 523.

The CHARACTERS are,

The flower has for the most part a double empalement, the outer being small and composed of three leaves, the inner is cut into five parts which are reflexed. It has five oblong petals which spread open, and fifteen narrow stamina joined in a tube at their base, with five long coloured summits, which are erect and barren; between each of these are three stamina, terminated by oblong erect summits. It has a roundish germen, with a cylindrical style the length of the stamina, crowned by a thick stigma. The germen afterward becomes an oval capsule with five cells, filled with oblong seeds.

This genus of plants is ranged in the third section of Linnaeus's sixteenth class, which includes those plants whose flowers have many stamina which are connected with the style, forming together a column.

We have but one SPECIES of this genus at present in the English gardens, viz.

PENTAPETES (*Phœnicia*) foliis hastato-lanceolatis serratis. Lin. Sp. Plant. 698. *Pentapetes with halbert-pointed, spear-shaped, sawed leaves.* Alcea Indica lucido hastato folio, flore bfattarie Phœnicio. Raii Supp. 523. *Indian Vervain Mallow with a lucid spear-shaped leaf, and a scarlet flower like Moth Mullein.*

This plant grows naturally in India, from whence I have several times received the seeds; it is an annual plant which dies in the autumn, soon after it has ripened the seeds. It hath an upright stalk from two to near three feet high, sending out side branches the whole length; those from the lower part of the stalks are the longest, the others gradually diminish, so as to form a sort of pyramid. These are garnished with leaves of different forms; the lower leaves, which are largest, are cut on their sides towards the base into two side lobes which are short, and the middle is extended two or three inches farther in length, so that the leaves greatly resemble the points of halberts in their shape; they are slightly sawed on their edges, and are of a lucid green on their upper side, but are paler on their under, standing upon pretty long foot-stalks. The leaves which are on the upper part of the branches are much narrower, and some of them have very small indentures on their sides; these sit closer to the stalks, and are placed alternately. From the wings of the stalks the flowers come out; they are for the most part single, but sometimes there are two arising at the same place from the sides of the foot-stalk of the leaves. The foot-stalk of the flower is short and slender. The exterior empalement of the flower is composed of three short leaves, which fall off soon; the interior is of one leaf, cut at the top into five acute segments, which spread open, and are almost as long as the petal. The flower is of one petal, cut into five obtuse segments almost to the bottom, but as they are joined and fall off in one piece, so the flower is monopetalous, according to Mr. Ray and Tournefort. In the center of the flower arises a short thick column, to which adhere fifteen short stamina, terminated by oblong erect summits, and between every third stamina is situated a larger stamina, with an oblong erect summit of a deep red colour; these

five large summits are barren, having no farina fecundens upon them. Between the stamina is situated a roundish germen, supporting a style the length of the stamina, which is crowned by a thick stigma. These being all joined at their base into a sort of column, distinguish the tribe to which it belongs, which is the malvaceous; so that though the flower at first appearance greatly resembles the flowers of Moth Mullein, yet upon examination of its essential characters, it will be found to belong to the class here mentioned. The flowers are of a fine scarlet colour, appearing in July; and are succeeded by roundish capsules with five cells, which are a little woody, each cell inclosing three or four oblong seeds, which ripen in the autumn.

The seeds of this plant must be sown upon a good hot-bed early in March, and when the plants are fit to transplant, there should be a new hot-bed prepared to receive them, into which should be plunged some small pots filled with good kitchen-garden earth; in each of these should be one plant put, giving them a little water to settle the earth to their roots; they must also be shaded from the sun till they have taken new root, then they should be treated in the same way as other tender exotic plants, admitting the free air to them every day in proportion to the warmth of the season, and covering the glasses with mats every evening to keep them warm. When the plants are advanced in their growth so as to fill the pots with their roots, they should be shifted into larger pots, filled with the same sort of earth as before, and plunged into another hot-bed, where they may remain as long as they can stand under the glasses of the bed without being injured; and afterward they must be removed either into a stove or a glass-case, where they may be screened from the cold, and in warm weather have plenty of fresh air admitted to them. With this management the plants will begin to flower early in July, and there will be a succession of flowers continued till the end of September, during which time they will make a good appearance. The seeds ripen gradually after each other in the same succession as the flowers were produced, so they should be gathered as soon as their capsules begin to open at the top. These plants are sometimes turned out of the pots, when they are strong and planted in warm borders, where, if the seasons prove very warm, the plants will flower pretty well; but these very rarely perfect their seeds, so that in order to have them in perfection, they must be treated in the manner before directed.

PENTAPHYLLOIDES. See **POTENTILLA**.

PENTHORUM. Gronov. Virg. 51. Lin. Gen. Plant. 580.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, cut into five equal segments; the flower has sometimes five small narrow petals situated between the segments of the empalement, and ten equal bristly stamina twice the length of the empalement, which are permanent, terminated by roundish deciduous summits. It hath a coloured germen with five styles the length of the stamina, crowned by obtuse stigmas; and a single five-cornered conical capsule having five cells, filled with small compressed seeds.

This genus of plants is ranged in the fourth section of Linnaeus's tenth class, intitled Decandria Pentagynia, which contains those plants whose flowers have ten stamina and five styles.

We have but one SPECIES of this genus, viz.

PENTHORUM (*Sedoides*.) Gron. Virg. 51. Lin. Sp. 620. *Penthorum like Houseleek.*

This is a biennial plant, which grows naturally in Virginia. The stalks rise about a foot high, garnished with oblong leaves placed alternately, and are terminated by clusters of greenish yellow flowers, which make little appearance; these are succeeded by five-cornered conical capsules, filled with small compressed seeds. The flowers appear the latter end of July, and the seeds ripen in the autumn.

P E R

As this plant makes but a mean appearance, so it is rarely cultivated, except in botanic gardens for the sake of variety; but such as are desirous to have it, should sow the seeds on a moist shady spot of ground, and when the plants come up, if they are thinned and kept clean from weeds, they will require no other culture.

PEONY. See PÆONIA.

PEPO. See CUCURBITA.

PERENNIAL PLANTS are such whose roots will abide many years, whether they retain their leaves in winter or not; those which retain their leaves are called Evergreens, but such as cast their leaves are called Deciduous or Perdifols. Some of these have annual stalks, which die to the root every autumn, and shoot up again in the spring; to which Jungius gives the title of Radix restibilis.

PERESKIA. Plum. Nov. Gen. 37. tab. 26. Cactus. Lin. Gen. Plant. 539. Gooseberry, vulgò.

The CHARACTERS are,

It hath a Rose-shaped flower consisting of several leaves, which are placed orbicularly, whose cup afterward becomes a soft, fleshy, globular fruit beset with leaves. In the middle of the fruit are many flat roundish seeds included in a mucilage.

We have but one SPECIES of this plant, viz.

PERESKIA (*Aculeata*) aculeata, flore albo, fructu flavascente. Plum. Nov. Gen. 37. *Prickly Pereskia with a white flower, and a yellowish fruit.* Cactus caule tereti arboreo spinoso, foliis lanceolato-ovatis. Lin. Hort. Upsal. 122. *Cactus with a taper, tree-like, prickly stalk, and spear-shaped oval leaves.*

This plant grows in some parts of the Spanish West-Indies, from whence it was brought to the English settlements in America, where it is called a Gooseberry, and by the Dutch it is called Blad Apple. It hath many slender branches which will not support themselves, so must be supported by stakes, otherwise they will trail on whatever plants grow near them. These branches, as also the stem of the plant, are beset with long whitish spines, which are produced in tufts. The leaves are roundish, very thick, and succulent, and the fruit is about the size of a Walnut, having tufts of small leaves on it, and hath a whitish mucilaginous pulp.

It may be propagated by planting of the cuttings during any of the summer months: these cuttings should be planted in pots filled with fresh light earth, and plunged into a moderate hot-bed of tanners bark, observing to shade them from the sun in the heat of the day, as also to refresh them every third or fourth day with water. In about two months the cuttings will have made good roots, when they may be carefully taken out of the pots, and each planted into a separate pot filled with fresh earth, and then plunged into the hot-bed again, where they may remain during the summer season; but at Michaelmas, when the nights begin to be cold, they should be removed into the stove, and plunged into the bark-bed. During the winter season the plants must be kept warm, and should be watered twice a week; but in cold weather it should not be given in large quantities. In summer they must have a large share of air, and must be more plentifully watered, but they should constantly remain in the stove; for though they will bear the open air in summer in a warm situation, yet they will make no progress if they are placed abroad; nor do they thrive near so well in the dry stove, as when they are plunged in the tan; so that the best way is to set them next a trellis, at the back of the tan-bed, to which their branches may be fastened, to prevent their trailing on other plants. This plant has not as yet produced either flowers or fruit in England, but as there are several plants pretty well grown in the gardens of the curious, we may expect some of them will flower in a short time.

PERICLYMENUM. Tourn. Inst. R. H. 608. tab. 578. Caprifolium. Tourn. Inst. R. H. 608. tab. 379. Lonicera. Lin. Gen. Plant. 210. Honeysuckle; in French, *Cbevre-feuille*.

P E R

The CHARACTERS are,

The empalement of the flower is small, and cut into five parts sitting upon the germen. The flower is of one petal, having an oblong tube, which is cut at the top into five segments which turn backward. It has five awl-shaped stamina almost the length of the petal, terminated by oblong summits, and a roundish germen situated below the flower, supported by a slender style, crowned by an obtuse stigma. The germen afterward becomes an umbilicated berry with two cells, each containing one roundish seed.

This genus of plants is by Dr. Linnæus placed in the first section of his fifth class, which includes those plants whose flowers have five stamina and one style, and joins it to the Lonicera of Plumier, and the Chamaecerasus of Tournefort; but as the flowers of this genus differ greatly in their form from either of those genera, so I have taken the liberty of separating it from them.

The SPECIES are;

1. PERICLYMENUM (*Sempervirens*) floribus capitatis terminalibus omnibus connatis sempervirentibus. *Honeysuckle with flowers growing in heads at the end of the branches, and evergreen leaves joined round the stalk. Periclymenum perfoliatum Virginianum sempervirens & florens. H. L. Perfoliate, evergreen, Virginia Honeysuckle which always flowers, commonly called Trumpet Honeysuckle.*
2. PERICLYMENUM (*Racemosum*) racemis lateralibus oppositis, floribus pendulis, foliis lanceolatis integerrimis. *Honeysuckle with flowers in long bunches growing opposite, hanging down, and entire spear-shaped leaves. Periclymenum racemosum flore flavascente, fructu niveo. Hort. Elth. 306. tab. 228. Honeysuckle with yellowish flowers growing in bunches, and a snowy fruit.*
3. PERICLYMENUM (*Verticillatum*) corymbis terminalibus, foliis ovatis verticillatis petiolatis. *Honeysuckle with round bunches of flowers at the end of the branches, and oval leaves growing in whorls, having foot-stalks. Periclymenum aliud arboreum ramulis inflexis, flore corallino. Plum. Cat. 17. Another tree-like Honeysuckle with inflexed branches, and a coral-coloured flower.*
4. PERICLYMENUM (*Germanicum*) capitulis ovatis imbricatis terminalibus, foliis omnibus distinctis. *Honeysuckle with oval imbricated heads terminating the stalks, and the leaves distinct. Caprifolium Germanicum. Dod. p. 411. The German Honeysuckle.*
5. PERICLYMENUM (*Italicum*) floribus verticillatis terminalibus sessilibus, foliis summis connato-perfoliatis. Hort. Cliff. 45. *Honeysuckle with whorls of flowers sitting close at the ends of the branches, and the upper leaves surrounding the stalk. Caprifolium Italicum. Dod. p. 411. Italian Honeysuckle.*
6. PERICLYMENUM (*Vulgare*) floribus corymbosis terminalibus, foliis hirsutis distinctis, viminibus tenuioribus. *Honeysuckle with a corymbus of flowers terminating the stalks, hairy leaves growing distinct, and very slender branches, commonly called English Honeysuckle, or Woodbine.*
7. PERICLYMENUM (*Americanum*) floribus verticillatis terminalibus sessilibus, foliis connato-perfoliatis sempervirentibus glabris. *Honeysuckle with whorled flowers sitting close, terminating the stalks, and smooth evergreen leaves surrounding the stalks. Caprifolium perfoliatum sempervirens, floribus speciosis. Hort. Chelf. The evergreen Honeysuckle, having beautiful flowers.*

The first sort grows naturally in Virginia, and many other parts of North America, but has been long cultivated in the English gardens by the title of Virginia Trumpet Honeysuckle. Of these there are two varieties, if not distinct species, one being much hardier than the other. The old sort, which came from Virginia, has stronger shoots; the leaves are of a brighter green; the bunches of flowers are larger, and deeper coloured than the other which came from Carolina. These plants have the appearance of the common Honeysuckle, but the shoots are weaker than any of those, except the wild sort called Woodbine; they are of a purplish red colour, and smooth. The leaves are of an oblong oval shape inverted, and

closely surround the stalk; of a lucid green on their upper side, but pale on their under. The flowers are produced in bunches at the end of the branches; these have long slender tubes, which are enlarged at the top, where they are cut into five almost equal segments. The outside of the flower is of a bright scarlet, and the inside yellow; they have great appearance of the Honeysuckle, but are not so deeply divided, nor are the segments reflexed. They have no odour, but for the beauty of their flowers, and their long continuance, together with their leaves being evergreen, they are preserved in most curious gardens.

These plants should be planted against walls or pales, to which their branches should be trained for support, otherwise they will fall to the ground; for they cannot be reduced to heads like many of the Honeysuckles, because their branches are too weak and rambling, and are liable to be killed in severe winters; therefore they should be planted to a warm aspect, where they will begin to flower the latter end of June, and there will be a succession of flowers till the autumn. These are propagated by laying down their young branches, which will easily take root, and may be afterward treated like the Honeysuckle.

The second sort grows naturally in Jamaica; this hath many slender branches which cannot support themselves, but trail upon any neighbouring bushes. They grow eight or ten feet long, are covered with a brown bark, and garnished with spear-shaped leaves about two inches and a half long, and one broad in the middle; of a lucid green on their upper side, but pale on their under, standing by pairs opposite. The flowers come out from the side of the branches at each joint; they are ranged on each side the foot-stalk in long bunches like Currants. The bunches come out opposite; they are three or four inches long. The flowers are small, of a yellowish green, and are succeeded by small berries of a snow white colour, from whence the plant is called Snowberry-bush in America.

The third sort grows naturally in some of the islands in the West-Indies; this rises with a shrubby stalk ten or twelve feet high, sending out many slender branches, covered with a light brown bark, garnished with oval leaves near two inches long, and an inch and a quarter broad, four of them coming out at each joint in whorls round the stalk; they stand upon short foot-stalks, and have one strong midrib, with several veins running from the midrib to the sides. The flowers come out in round bunches at the end of the branches; they are of a deep coral colour on their outside, but of a pale red within. This was found growing in Jamaica by the late Dr. Houstoun, who brought it to England.

These two sorts are too tender to thrive in this country without artificial heat; they are propagated by seeds, which must be procured from the countries where they naturally grow, for they do not ripen seeds here. These should be sown in pots, and plunged into a moderate hot-bed, where they may remain till the autumn, for the plants rarely come up the first year; so the pots should be removed into the stove for the winter season, and the following spring placed on a fresh hot-bed, which will bring up the plants; and when they are fit to remove, they should be each planted in a separate small pot filled with light earth, and plunged into a fresh hot-bed, shading them from the sun till they have taken new root, after which they must be treated in the manner as other tender plants from those countries. As the plants obtain strength, they should be more hardily treated, by placing them abroad in a sheltered situation for two months or ten weeks, in the warmest part of the summer, and in the winter they may be placed in a dry stove, kept to a moderate temperature of warmth, where they will thrive, and produce their flowers in the autumn.

The fourth sort is the common Dutch or German Honeysuckle, which has been generally supposed the

same with the English wild sort called Woodbine, but is undoubtedly a very different species, for the shoots of this are much stronger. The plants may be trained with stems, and formed into heads, which the wild sort cannot, their branches being too weak and trailing for this purpose. The branches of this are smooth, of a purplish colour, garnished with oblong oval leaves three inches long, and an inch and three quarters broad, of a lucid green on their upper side, but pale on their under, having very short foot-stalks; they are placed by pairs, but are not joined at their base. The flowers are produced in bunches at the end of the branches, each flower arising out of a scaly cover, which cover, after the flowers fade, forms an oval head, whose scales lie over each other like those outside, and yellowish within, of a very agreeable of fish. The flowers are of a reddish colour on their odour. This sort flowers in June, July, and August. There are two other varieties of this species, one is called the long blowing, and the other the late red Honeysuckle.

The fifth sort is commonly called the Italian Honeysuckle; of this there are two or three varieties, the early white Honeysuckle is one; this is the first which flowers, always appearing in May. The branches of this are slender, covered with a light green bark, and garnished with oval leaves of a thin texture, placed by pairs, sitting close to the branches, but those which are situated toward the end of the branches, join at their base, so that the stalk seems as if it came through the leaves. The flowers are produced in whorled bunches at the end of the branches; they are white, and have a very fragrant odour, but are of short duration, so that in about a fortnight they are entirely over; and soon after the leaves appear as if blighted and sickly, making an indifferent appearance the whole summer, which has rendered them less valued than the others. The other variety is the yellow Italian Honeysuckle, which is the next in succession to the white. The shoots of this are much like those of the former, but have a darker bark; the leaves are also of a deeper green; the flowers are of a yellowish red, and appear soon after the white; they are not of much longer duration, and are succeeded by red berries, containing one hard seed inclosed in a soft pulp, which ripens in the autumn.

The sixth sort is the common wild English Honeysuckle or Woodbine; this grows naturally in the hedges in many parts of England. The branches are very slender and hairy, trailing over the neighbouring bushes, and twining round the boughs of trees; the leaves are oblong, hairy, and distinct, not joined at their base; they are placed opposite; the flowers are produced in long bunches at the end of the branches. There are two varieties, one with white, and the other yellowish red flowers. These appear in July, and there is a succession of flowers till the autumn.

There is also a variety of this with variegated leaves, and one with cut leaves somewhat like the leaves of Oak, and one of these with variegated leaves; but, as these are accidental varieties, I have not enumerated them.

The seventh sort, is supposed to grow naturally in North America; this hath strong branches, covered with a purple bark, which are garnished with lucid green leaves embracing the stalks, which continue their verdure all the year. The flowers are produced in whorled bunches at the end of the branches; there are frequently two and sometimes three of these bunches rising one out of another; they are of a bright red on their outside, and yellow within, of a strong aromatic flavour. This sort begins to flower in June, and there is a succession of flowers till the frost puts a stop to them, so that it is the most valuable of all the sorts.

All the sorts of Honeysuckles are propagated either by layers or cuttings: when they are propagated by layers, the young shoots only should be chosen for that purpose; they should be layed in the autumn,

and by the following autumn they will have taken root, when they should be cut off from the plants, and either planted where they are to remain, or into a nursery to be trained up, either for standards, which must be done by fixing down stakes to the stem of each plant, to which their principal stalk should be fattened, and all the other must be cut off; the principal stalk must be trained to the intended height of the stem, then it should be shortened to force out lateral branches, and these should be again stopped to prevent their growing too long; by the constant repeating this as the shoots are produced; they may be formed into a sort of standard; but if any regard is had to their flowering, they cannot be formed into regular heads, for by constantly shortening their branches, the flower-buds will be cut off, so that few flowers can be expected; and as it is an unnatural form for these trees, so there should be but few of them reduced to it, for when they are planted near other bushes, in whose branches the shoots of the Honeyuckles may run and mix, they will flower much better, and have a finer appearance than when they are more regularly trained; therefore, when the plants are in the nursery, if two or three of the principal shoots are trained up to the stakes, and the others are entirely cut off, they will be fit to transplant the following autumn, to the places where they are to remain; for though the roots may be transplanted of a greater age, yet they do not thrive so well as when they are removed while they are young. When these plants are propagated by cuttings, they should be planted in September, as soon as the ground is moistened by rain. The cuttings should have four joints, three of which should be buried in the ground, and the fourth above the surface, from which the shoots should be produced. These may be planted in rows, at about a foot distance row from row, and four inches asunder in the rows, treading the earth close to them; and as the evergreen and late red Honeyuckles, are a little more tender than the other sorts, so if the ground between the rows where these are planted, is covered with tanners bark or other mulch to keep out the frost in winter, and the drying winds of the spring, it will be of great advantage to the cuttings; and if the cuttings of these sorts have a small piece of the two years wood at their bottom, there will be no hazard of their taking root. The plants which are raised from cuttings, are preferable to those which are propagated by layers, as they have generally better roots.

These plants will grow in almost any soil or situation (except the last mentioned, which will not thrive where they are too much exposed to the cold in winter) they thrive best in a soft sandy loam, and will retain their leaves in greater verdure in such ground than if planted in a dry gravelly soil, where in warm dry seasons their leaves often shrink, and hang in a very disagreeable manner; nor will those sorts which naturally flower late in the autumn, continue so long in beauty on a dry ground, unless the season should prove moist and cold, as those in a gentle loam, not too stiff or wet.

There are few sorts of shrubs which deserve cultivation better than most of these, for their flowers are very beautiful, and perfume the air to a great distance with their odour, especially in the mornings and evenings, and in cloudy weather, when the sun does not exhale their odour, and raise it too high to be perceptible; so that in all retired walks, there cannot be too many of these intermixed with the other shrubs. I have seen these plants intermixed in hedges planted either with Alder or Laurel, where the branches have been artfully trained between those of the hedge; from which the flowers have appeared dispersed from the bottom of the hedge to the top, and being intermixed with the strong green leaves of the plants which principally compose the hedge, they have made a fine appearance; but the best sorts for this purpose, are the evergreen and long-blowing Honeyuckles, be-

cause their flowers continue in succession much longer than the other sorts.

These plants may be propagated by seeds, but unless they are sown in the autumn soon after they are ripe, the plants will not come up the first year.

PERIPLOCA. Tourn. Inst. R. H. 93. tab. 22. Lin. Gen. Plant. 267. [*Περιπλοκή*, of *περί*, about, and *πλοκή*, a knitting or plaiting, because this plant entangles itself with itself, or any other neighbouring plants.] Virginian Silk.

The CHARACTERS are,

The flower hath a small permanent empalement, cut into five points. The flower has one plain petal, cut into five narrow segments, which are indented at their points, with a small nectarium going round the center of the petal, and the five incurved filaments which are not so long as the petal, and five short stamina terminated by erect summits which join in a head. It has a small bifid germen with scarce any style, crowned by two simple stigmas. The germen afterward becomes two oblong bellied capsules with one cell, filled with seeds crowned with down, lying over each other like the scales of fish.

This genus of plants is ranged in the second section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and two styles.

The SPECIES are,

1. **PERIPLOCA** (*Græca*) floribus internè hirsutis. Lin. Sp. Plant. 211. *Virginia Silk, with flowers hairy on their inside.* Periploca foliis oblongis. Tourn. Inst. R. H. 93. *Virginia Silk with oblong leaves.*
2. **PERIPLOCA** (*Africana*) caule hirsuto. Lin. Sp. Plant. 211. *Virginia Silk with a hairy stalk.* Apocynum scandens, Africanum, vincæ pervincæ folio subincanum. Com. Plant. Rar. 18. *Climbing African Dogbane, with a hoary Periwinkle leaf.*
3. **PERIPLOCA** (*Fruticosa*) foliis oblongo-cordatis pubescentibus, floribus alaribus, caule fruticoso scandente. *Virginia Silk, with oblong heart-shaped leaves which are covered with soft hairs, and flowers proceeding from the sides of the stalks, which are shrubby.* Periploca foliis cordatis holosericeis, floribus parvis, albis, campaniformibus. Houst. MSS. *Periploca with heart-shaped silky leaves, and small, white, bell-shaped flowers.*

The first sort grows naturally in Syria, but is hardy enough to thrive in the open air in England. It hath twining shrubby stalks, covered with a dark bark, which twist round any neighbouring support, and will rise more than forty feet high, sending out slender branches from the side, which twine round each other, and are garnished with oval spear-shaped leaves near four inches long, and two broad in the middle, of a lucid green on their upper side, but pale on their under, standing by pairs, upon short foot-stalks. The flowers come out toward the end of the small branches in bunches; they are of a purple colour, and hairy on their inside, composed of one petal, cut into five segments almost to the bottom, which spread open in form of a star, and within is situated a nectarium, which goes round the five short stamina and germen, and is hairy. The germen afterward turns to a double long taper pod or capsule, filled with compressed seeds, lying over each other like the scales of fish, having a soft down fixed to their top. This plant flowers in July and August, but rarely ripens its seeds in England.

It is easily propagated by laying down of the branches, which will put out roots in one year, and may then be cut from the old plant, and planted where they are to remain. These may be transplanted either in autumn, when the leaves begin to fall, or in the spring before they begin to shoot, and must be planted where they may have support, otherwise they will trail on the ground, and fasten themselves about whatever plants are near them.

The second sort grows naturally in Africa; this hath many slender stalks, which twine about each other, or any neighbouring support, and will rise near three feet high, putting out several small side branches; these are hairy, as are also the leaves, which are oval, about

P E R

about three quarters of an inch long, and half an inch broad, standing by pairs upon very short foot-stalks. The flowers come out in small bunches from the side of the stalks; they are small, and of a worn-out purplish colour, and a sweet scent, being cut into five narrow segments almost to the bottom. It flowers in the summer months, but does not produce seeds here. There is a variety of this with smooth leaves and stalks, from the same country.

The third sort was discovered by the late Dr. Houttoun, growing naturally at La Vera Cruz in America. This rises with a strong woody stalk to the height of five or six feet, covered with a gray bark, putting out many weak branches, which twist themselves about any neighbouring support, and rise to the height of twenty feet; they are garnished with heart-shaped leaves three inches long, and two broad near their base; they are of a yellowish green, covered with silky hairs, which are soft to the touch; they stand opposite upon pretty long foot-stalks. The flowers come out in small bunches from the wings of the leaves; they are small, white, and of the open bell shape; these are succeeded by swelling taper pods, filled with seeds crowned with long feathery down.

The second sort is hardy enough to thrive in this country, with a little protection from the frost in winter. If the plants are sheltered under a common frame or placed in a green-house during the winter season, and placed abroad with other hardy exotic plants in summer, they will thrive and flower very well; but as all the plants of this genus have a milky juice, so they should not have much wet, especially in cold weather, lest it rot them. They are easily propagated by laying down of their branches, which in one year will have roots enough to transplant; these should be planted in a light sandy loam not rich, and the pots must not be too large, for when they are over potted they will not thrive.

The third sort is tender, so will not thrive in England, unless the plants are placed in a warm stove. They may be propagated by laying down of their branches in the same manner as the former; or from seeds, when they can be procured from the places where they naturally grow. These should be sown upon a good hot-bed, and when the plants come up, they must be treated in the same manner as other tender exotic plants.

If these plants are constantly kept plunged in the tan-bed of the stove, they will thrive and flower much better than in any other situation, but the stove should not be kept too warm in winter; and in the summer the plants should have a large share of free air admitted to them; for when they are kept too close, their leaves will be covered with insects, and the plants will become sickly in a short time.

All the species of this genus are supposed to be hurtful to animals, as the Dogbanes in general are, and these are very near a-kin to them, both in their characters and qualities.

PERIWINKLE. See VINCA.

PERSEA. Plum. Nov. Gen. 44. tab. 20. Laurus. Lin. Gen. Plant. 452. The Avocado, or Avogato Pear.

The CHARACTERS are,

The flower hath no empalement, but is composed of six petals ending in acute points, which spread open. It hath six stamina which are about half the length of the petals, terminated by roundish summits, and a short style, crowned by a pyramidal germen, which afterward becomes a large fleshy pyramidal fruit, inclosing an oval seed having two lobes.

This genus of plants Dr. Linnæus has joined to his genus of Laurus, which he places in the first section of his ninth class, which includes those plants whose flowers have nine stamina and one style.

We have but one SPECIES of this plant, viz.

PERSEA (Americana.) Clus. Hist. The Avocado, or Avogato Pear.

This tree grows in great plenty in the Spanish West-

P E R

Indies, as also in the island of Jamaica, and hath been transplanted into most of the English settlements in the West-Indies on account of its fruit; which is not only esteemed by the inhabitants as a fruit to be eaten by way of desert, but is very necessary for the support of life. The fruit of itself is very insipid, for which reason they generally eat it with the juice of Lemons and sugar, to give it a piquancy. It is very nourishing, and is reckoned a great incentive to venery. Some people eat this fruit with vinegar and Pepper.

In the warm countries where this is planted, it grows to the height of thirty feet or more, and has a trunk as large as our common Apple-trees; the bark is smooth, and of an Ash colour; the branches are beset with pretty large, oblong, smooth leaves, like those of Laurel, which are of a deep green colour, and continue on the tree throughout the year. The flowers and fruit are, for the most part, produced toward the extremity of the branches. The fruit is as large as one of the largest Pears, inclosing a large seed with two lobes, included in a thin shell.

In Europe this plant is preserved as a curiosity, by those persons who delight in collecting exotic plants; and though there is little hope of its producing fruit, yet for the beauty of its shining green leaves, which continue through the winter, it deserves a place in every curious collection of plants.

It is propagated by seeds, which should be obtained as fresh as possible from the countries of its growth; and if they are brought over in sand, will be more likely to grow, than such as are brought over dry. These nuts or seeds should be planted in pots, filled with light rich earth, and plunged into a hot-bed of tanners bark, which should be kept pretty warm. The pots should be also frequently watered when the earth appears dry, which will greatly facilitate the vegetation of the seed, provided the water is not given in large quantities, which would rot them. In about five or six weeks the plants will come up, when they must be treated very tenderly, for the bed must be kept in a due temperature for heat; and when the weather proves warm, the fresh air should be admitted to the plants, by raising the glasses a little. When they have grown about four inches high, they should be carefully transplanted; and where there are several plants in one pot, they must be parted, being careful to preserve a ball of earth to the root of each, and planted into separate small pots filled with light rich earth, and then plunged into a hot-bed of tanners bark, observing to shade them until they have taken new root; after which time they should have fresh air admitted to them, in proportion to the warmth of the season. Towards Michaelmas the plants must be removed into the stove, and plunged into the bark-bed, where, during the winter season, they should be kept in a moderate warmth, and must be gently watered twice a week. In the spring the plants should be shifted into pots a size larger than the former, and the bark-bed should be then renewed with fresh tan, which will set the plants in a growing state early, whereby they will make a fine progress the following summer. These plants must be constantly kept in the stove, for they are too tender to bear the open air in this country at any season, but in warm weather should have a large share of air admitted to them.

PERSICA. Tourn. Inst. R. H. 624. tab. 402. [so called of Persia in Asia, from whence this kind of plant was brought into our climate.] The Peach-tree. Amygdalus. Lin. Gen. 619.

The CHARACTERS are,

The flower has a tubulous empalement of one leaf, cut into five obtuse segments which spread open. It hath five oblong, oval, obtuse petals, which are inserted in the empalement, and about thirty erect slender stamina which are shorter than the petals, terminated by single summits; these are also inserted in the empalement. It hath a roundish hairy germen, supporting a style the length of the stamina, crowned by a beaded stigma. The germen afterward

afterward becomes a roundish, woolly, large, excellent fruit, with a longitudinal furrow, inclosing an oval nut with a netted shell, having many punctures.

This genus of plants is ranged in the first section of Linnaeus's twelfth class, which includes those plants whose flowers have from twenty to thirty stamina, which are inserted in the empalement of the flower, and one style.

There is a great variety of these trees, which are cultivated in the gardens of those who are curious in collecting the several sorts of fruit from the different parts of Europe: I shall therefore first beg leave to mention two or three sorts, which are cultivated for the beauty of their flowers; after which I shall enumerate the several varieties of good fruit which have come to my knowledge.

The SPECIES are,

1. PERSICA (*Vulgaris*) vulgaris, flore pleno. Tourn. Inst. R. H. 625. *Common Peach-tree with double flowers.*
2. PERSICA (*Nana*) Africana nana, flore incarnato simplici. Tourn. Inst. R. H. 625. *Dwarf Almond with single flowers, vulgò.*
3. PERSICA (*Amygdalus*) Africana nana flore incarnato pleno. Tourn. Inst. R. H. 925. *Double flowering Dwarf Almond, vulgò.*

The first of these trees is a very great ornament in a garden early in the spring, the flowers being very large, double, and of a beautiful red or purple colour. This may be planted in standards, and if intermixed with other flowering trees of the same growth, makes a very agreeable variety; or it may be planted against the walls of the pleasure-garden, where the beautiful appearance of its flowers early in the spring, will be more acceptable in such places than the choicest fruits, which must be exposed to servants, and others, so that they seldom can be preserved in large families until they are ripe. This tree may be propagated by budding it on the Almond or Plum stocks, in the same manner as the other sort of Peaches, and should be planted in a good fresh soil that is not over moist.

The other two sorts are of humbler growth, seldom rising above three or four feet high; these may be budded upon Almond stocks, or propagated by layers; they will also take upon Plum stocks, but they are very apt to canker, after they have stood four or five years upon those stocks, especially that with double flowers, which is tenderer than the other, which sends out suckers from the root, whereby it may be propagated in great plenty.

These shrubs make a very agreeable variety amongst low flowering trees, in small wilderness quarters. The single sort flowers in the beginning of April, and the double is commonly three weeks later.

I shall now proceed to mention the sorts of good Peaches which have come to my knowledge; and though perhaps a greater number of sorts may be found in some catalogues of fruits, yet I doubt whether many of them are not the same kinds called by different names; for, in order to determine the various kinds, it is necessary to observe the shape and size of the flowers, as well as the different parts of the fruit; for this does sometimes determine the kind, when the fruit alone is not sufficient; besides, there is a vast difference in the size and flavour of the same Peach, when planted on different soils and aspects; so that it is almost impossible for a person who is very conversant with these fruits to distinguish them, when brought from various gardens.

The present confusion of the names of fruits, hath been many times owing to the bringing over trees from France; for the persons who are generally employed to bring over those trees for sale, are entirely ignorant of their various sorts, and do themselves take them upon trust, from the persons who make it their business to propagate great quantities, to supply the markets of France, whither they are brought in waggon, and sold out in parcels to those persons who bring them into England. It also happens many times, if they are received by right names, that these

in length of time are lost, or the trees come into the possession of other persons, who not knowing the true name of the fruit, do often give them new names, whereby there is such a confusion in the names of fruit, as is impossible to rectify; and hence some persons have supposed a much greater variety of Peaches than there is in reality, though as the greatest part of these have been obtained from seeds, so their varieties may be multiplied annually, until there be no end of the sorts. However, I shall content myself with enumerating the principal sorts now known in England, which are sufficient for any gentleman to make a collection to continue through the whole season of fruit.

1. The white Nutmeg (called by the French, L'Avant Pêche Blanche:) this tree has sawed leaves, but generally shoots very weak, unless it is budded upon an Apricot stock; the flowers are large and open, the fruit is small and white, as is also the pulp at the stone, from which it separates; it is a little musky and sugary, but is only esteemed for its being the first sort ripe. It is in eating pretty early in July, and soon becomes meally.

2. The red Nutmeg (called by the French, L'Avant Pêche de Troyes:) this tree has sawed leaves, the flowers are large and open; the fruit is larger and rounder than the white Nutmeg, and is of a bright vermilion colour; the flesh is white, and very red at the stone; it has a rich musky flavour, and parts from the stone. This Peach is well esteemed, it ripens toward the end of July.

3. The early or small Mignon (called by the French, La Double de Troyes, or Mignonette:) this tree has small contracted flowers, the fruit is of a middling size, and round; it is very red on the side next the sun; the flesh is white, and separates from the stone, where it is red; the juice is vinous and rich. It is ripe the end of July, or beginning of August.

4. The yellow Alberge: this tree has smooth leaves; the flowers are small and contracted; the fruit is of a middling size, somewhat long; the flesh is yellow and dry; it is seldom well flavoured, but should be perfectly ripe before it is gathered, otherwise it is good for little. It is ripe early in August.

5. The white Magdalen: this tree has sawed leaves; the flowers are large and open; the wood is generally black at the pith; the fruit is round, of a middling size; the flesh is white to the stone, from which it separates; the juice is seldom high flavoured; the stone is very small. This ripens early in August.

6. The early purple (called by the French, La Pourprée hâtive:) this tree has smooth leaves; the flowers are large and open; the fruit is large, round, and of a fine red colour; the flesh is white, but very red at the stone; is very full of juice, which has a rich vinous flavour, and is by all good judges esteemed an excellent Peach. This is ripe before the middle of August.

7. The large or French Mignon: the leaves of this tree are smooth; the flowers are large and open; the fruit is a little oblong, and generally swelling on one side; it is of a fine colour; the juice is very sugary, and of a high flavour; the flesh is white, but very red at the stone, which is small. This is ripe in the middle of August, and is justly esteemed one of the best Peaches; this separates from the stone. This sort of Peach is tender, and will not thrive on a common stock, so is generally budded upon some vigorous shooting Peach, or an Apricot, by the nurserymen, which enhances the price of the trees. But the best method is to bud this Peach into some old healthy Apricot, which is planted to a south or south-east aspect, and to cut away the Apricot when the buds have taken, and made shoots: upon some trees which I have seen thus managed, there has been a much greater quantity of fairer, and better flavoured fruit than I have ever observed elsewhere, and the trees have been much more healthy.

8. The Chevreuse, or Belle Chevreuse: this tree has smooth leaves; the flowers are small and contracted; the

the fruit is of a middling size, a little oblong, of a fine red colour; the flesh is white, but very red at the stone, from which it separates; it is very full of a rich sugary juice, and ripens toward the end of August. This is a very good bearer, and may be ranged with the good Peaches.

9. The red Magdalen (called by the French about Paris, Madeleine de Courlon :) the leaves of this tree are deeply sawed; the flowers are large and open; the fruit is large and round, of a fine red colour; the flesh is white, but very red at the stone, from which it separates; the juice is very sugary, and of an exquisite flavour. The fruit is ripe the end of August; it is one of the best sort of Peaches.

10. The early Newington (or Smith's Newington :) this is very like, if not the same, with what the French call Le Pavie blanc. This tree has sawed leaves; the flowers are large and open; the fruit is of a middling size, is of a fine red on the side next the sun; the flesh is firm and white, but very red at the stone, to which it closely adheres. It hath a sugary juice, and is ripe the end of August.

11. The Montauban: this tree has sawed leaves; the flowers are large and open; the fruit is of a middling size, of a deep red, inclining to purple next the sun, but of a pale colour toward the wall; the flesh is melting and white to the stone, from which it separates; the juice is rich, and the tree is a good bearer. It ripens the middle of August, and is well esteemed.

12. The Malta (which is very like, if not the same, with the Italian Peach :) this tree has sawed leaves; the flowers are large and open; the fruit is of a middling size, of a fine red next the sun: the flesh is white and melting, but red at the stone, from which it separates; the stone is flat and pointed; the tree is a good bearer. This ripens the end of August.

13. The Noblest: this tree has sawed leaves; the flowers are large and open; the fruit is large, of a bright red next the sun; the flesh is white and melting, and separates from the stone, where it is of a faint red colour; the juice is very rich in a good season. It ripens the end of August.

14. The Chancellor: the leaves of this tree are smooth; the flowers are small and contracted; the fruit is shaped somewhat like the Belle Chevreuse, but is rounder; the flesh is white and melting, and separates from the stone, where it is of a fine red colour; the skin is very thin, and the juice is very rich. It ripens about the end of August, and is esteemed one of the best sort of Peaches. This tree is very tender, and will not succeed on common stocks, so is budded twice as the Mignon; and if budded on Apricots, as was directed for that sort, will thrive much better than in any other method.

15. The Bellegarde (or as the French call it, the Gallande :) this tree has smooth leaves; the flowers are small and contracted; the fruit is very large and round, of a deep purple colour on the side to the sun; the flesh is white, melting, and separates from the stone, where it is of a deep red colour; the juice is very rich. This ripens the beginning of September, and is an excellent Peach, but at present not common.

16. The Lisle (or as the French call it, La petite Violette hâtive :) this tree has smooth leaves; the flowers are small and contracted; the fruit is of a middling size, of a fine Violet colour toward the sun; the flesh is of a pale yellow and melting, but adheres to the stone, where it is very red; the juice is very vinous. This ripens the beginning of September.

17. The Bourdine: this tree has smooth leaves; the flowers are small and contracted; the fruit is large, round, and of a fine red colour next the sun; the flesh is white, melting, and separates from the stone, where it is of a fine red colour; the juice is vinous and rich; this ripens the beginning of September, and is greatly esteemed by the curious. The tree bears plentifully, and will produce fruit in standards very well.

18. The Rossanna: this tree has smooth leaves; the flowers are small and contracted; the fruit is large, a little longer than the Alberge; the flesh is yellow and separates from the stone, where it is red; the juice is rich and vinous. This ripens the beginning of September, and is esteemed a good Peach. This is the same with what some call the purple, and others the red Alberge, it being of a fine purple colour on the side next the sun.

19. The Admirable: this tree hath smooth leaves; the flowers are small and contracted; the fruit is large, round, and red on the side next the sun; the flesh is white, melting, and separates from the stone, where it is of a deep red colour; the juice is sugary and rich. This ripens the beginning of September. This is by some called the early Admirable, but is certainly what the French call L'Admirable, and they have no other of this name which ripens later.

20. The old Newington: this tree has sawed leaves; the flowers are large and open; the fruit is fair and large, of a beautiful red colour next the sun; the flesh is white, melting, and closely adheres to the stone, where it is of a deep red colour; the juice is very rich and vinous. This is esteemed one of the best sorts of Pavies. It ripens about the middle of September.

21. The Rambouillet (commonly called Rumbullion :) this tree has smooth leaves; the flowers are large and open; the fruit is of a middling size, rather round than long, deeply divided by a sulcus or furrow in the middle; it is of a fine red colour next the sun, but of a light yellow next the wall; the flesh is melting, of a bright yellow colour, and separates from the stone, where it is of a deep red colour; the juice is rich, and of a vinous flavour. This ripens the middle of September, and is a good bearer.

22. The Bellis (which I believe to be what the French call La Belle de Vitry :) the leaves of this tree are sawed; the flowers are small and contracted; the fruit is of a middle size, round, and of a pale red next the sun; the flesh is white and adheres to the stone, where it is red; the juice is vinous and rich. This ripens the middle of September.

23. The Portugal: this tree has smooth leaves; the flowers are large and open; the fruit is large, and of a beautiful red colour towards the sun, the skin generally spotted; the flesh is firm, white, and closely adheres to the stone, where it is of a faint red colour; the stone is small, but full of deep furrows; the juice is rich and vinous. This ripens the middle of September.

24. La Téton de Venus (or Venus's breast,) so called from its having a rising like a dug, or bubbly: this tree has smooth leaves; the flowers are small and contracted; the fruit is of a middling size resembling the Admirable, of a pale red colour next the sun; the flesh is melting, white, and separates from the stone, where it is red; the juice is sugary and rich. This ripens late in September.

25. La Pourprée (or as the French call it Pourprée tardive, i. e. the late purple :) this tree has very large leaves which are sawed; the shoots are very strong; the flowers are small and contracted; the fruit is large, round, and of a fine purple colour; the flesh is white, melting, and separates from the stone, where it is red; the juice is sugary and rich. This ripens late in September.

26. The Nivette: this tree has sawed leaves; the flowers are small and contracted; the fruit is large, somewhat longer than round, of a bright red colour next the sun, and of a pale yellow on their other side; the flesh is melting, and full of rich juice, and is very red at the stone, from which it separates. This is esteemed one of the best Peaches; it ripens in the middle of September.

27. The Royal (La Royale :) this tree has smooth leaves; the flowers are small and contracted; the fruit is large, round, and of a deep red on the side next the sun, and of a paler colour on the other side; the flesh is white, melting, and full of a rich juice; it parts from the stone, where it is of a deep red colour.

lour. This ripens the middle of September, and, when the autumn is good, is an excellent Peach.

28. The *Perfique*: this tree has sawed leaves; the flowers are small and contracted; the fruit is large, oblong, and of a fine red colour next the sun; the flesh is melting, and full of a rich juice; it separates from the stone, where it is of a deep red colour. The stalk has a small knot upon it; this makes a fine tree, and is a good bearer; it ripens the end of September. Many gardeners call this the *Nivette*.

29. The monstrous *Pavy* of *Pomponne* (called by the French, *La Pavie rouge de Pomponne*): the leaves of this tree are smooth; the flowers are large and open; the fruit is very large and round, many times fourteen inches in circumference; the flesh is white, melting, and closely adheres to the stone, where it is of a deep red colour; the outside is a beautiful red next the sun, and of a pale flesh colour on the other side. This ripens the end of October, and when the autumn is warm, is an excellent Peach.

30. The *Catharine*: this tree hath smooth leaves; the flowers are small and contracted; the fruit is large, round, and of a dark red colour next the sun; the flesh is white, melting, and full of a rich juice. It closely adheres to the stone, where it is of a deep red colour; it ripens the beginning of October, and in very good seasons is an excellent Peach, but being so very late ripe, there are not many situations where it ripens well.

31. The *Bloody Peach* (called by the French, *La Sanguinolle*): this Peach is of a middling size, of a deep red next the sun; the flesh is of a deep red quite to the stone, and from thence is by some gardeners called the *Mulberry Peach*. This fruit rarely ripens in England, so is not often planted, but it bakes and preserves excellently; for which, as also the curiosity, one or two trees may be planted, where there is extent of walling.

There are some other sorts of Peaches which are kept in some of the nurseries, but those which are here enumerated, are the sorts most worth planting, and in the list, the choicest only should be planted; but I shall just mention the names of those sorts omitted, for the satisfaction of the curious.

The *Sion*; the *Bordeaux*; the *Swalch* or *Dutch*; the *Carlisle*; the *Eaton*; the *Pêche de Pau*; yellow *Admirable*; the *double Flower*. This last sort is generally planted more for the beauty of the flowers, than for the goodness of the fruit, of which some years the standard trees produce great plenty; but they are late ripe, and have a cold, watery, insipid juice. The *Dwarf Peach* is also preserved in some places as a curiosity. This is a very tender tree, making very weak shoots, which are very full of flower-buds. The fruit is not so large as a *Nutmeg*, and not good, nor will the tree last any time, so it is not worth cultivating.

And indeed, from these thirty-one above-named, there are not above ten of them which I would advise to be planted; because, when a person can be furnished with those which are good, or has the best of the season, it is not worth while to plant any which are middling or indifferent, for the sake of variety; therefore the sorts which I should prefer, are these after-mentioned.

The early purple; the *Grosse Mignon*; *Belle Chevreuse*; red *Magdalen*; *Chancellor*; *Bellegarde*; *Bourdine*; *Rossanna*; *Rambouillet*, and *Nivette*. These are the sorts best worth planting; and as they succeed each other, they will furnish the table thro' the season of Peaches; and, where there is room, and the situation very warm, one or two trees of the *Catharine Peach* should have place, for in very warm seasons it is an excellent fruit.

As these eleven sorts do follow each other in their time of ripening, so unless there is extent of good aspected walls, these will be sufficient to furnish any family during the season of this fruit: but as in some seasons there will be some sorts of Peaches very good, which in other seasons often prove but indifferent; there-

fore when there is a sufficient extent of good walls, I would recommend the planting three or four other sorts, which some years are excellent, though in general are not so good as those before-mentioned. These are the *Montauban*, the *Lisle*, the old *Newington*, *La Teton de Venus*, the *Catharine*, and the *Perfique*.

The French distinguish those we call Peaches into two sorts, viz. *Pavies* and *Peaches*; those are called *Peaches* which quit the stone, and those, whose flesh closely adheres to the stone, are called *Pavies*. These are much more esteemed in France than the *Peaches*, though in England the latter are preferred to the former by many persons.

The French also distinguish them into male and female; the *Pavies* they make to be the male, and the *Peaches* the female; but this division is without foundation, since the kernels of both sorts will produce trees equally; for the flowers of Peach-trees are generally hermaphrodite, and have all the parts of generation in them, so that there is no necessity for supposing any of them to be entirely male or female: but it is likely, that this distinction is of long standing, before persons had a perfect notion of male and female in plants, or at least they did not know how to distinguish them asunder.

The *Nectarines* (as I have in another place said) are by the French called *Brugnons*, which differ from the other two sorts, in having a firm hard flesh, and the skin quite smooth, without any down upon them. The sorts of these I have already mentioned under the article *NECTARINES*, to which the reader may readily turn, therefore I shall not repeat them in this place.

I shall now set down the good qualities of *Peaches*, by which any person may judge of their worth.

A good Peach ought to have a firm flesh; the skin should be thin, of a deep or bright red colour next the sun, and of a yellowish cast next the wall. The flesh should be of a yellowish colour, full of juice, which should be high-flavoured, the stone small, and the pulp or flesh very thick. When a Peach hath all these qualities, it may be esteemed a valuable fruit.

All the different sorts of *Peaches* have been originally obtained from the stones, which, being planted produce new varieties, as do the seeds of all other fruits; so that where persons have garden enough to allow room for propagating these fruits from seeds, there is no doubt but many good sorts may be obtained, which will be better adapted to our climate, than such as are brought from warmer countries; though it is true, that there will be many of them good for nothing, as is the case of most fruits and flowers which are produced from seeds, amongst which there may be some valuable kinds, superior to those from whence the seeds were taken, yet there is always a great number which are little worth; but if we can obtain only two or three valuable sorts, it is sufficient to make amends for the trouble of raising them; but where persons are so curious as to plant the stones of these fruits, great regard should be had to the sorts; and if the fruits were permitted to remain upon the trees until they dropped off, the kernels would be fitter for planting, and more likely to grow. The best sorts for sowing are those whose flesh is firm, and cleaves to the stone; and from amongst these you should chuse such as ripen pretty early, and have a rich vinous juice, from which sorts some good fruit may be expected.

These stones should be planted in autumn, on a bed of light dry earth, about three inches deep, and four inches asunder; and in the winter the beds should be covered to protect them from the frost, which, if permitted to enter deep into the ground, will destroy them. In the spring, when the plants come up, they should be carefully cleared from the weeds, which should also be observed throughout the summer; and if the spring should prove very dry, if you refresh them now and then with a little water, it will greatly promote their growth. In this bed they should remain

main until the following spring, when they should be carefully taken up, so as not to break their tender roots, and transplanted into a nursery in rows three feet asunder, and one foot distant plant from plant in the rows, observing to lay a little mulch upon the surface of the ground about their roots, to prevent its drying too fast; and if the spring should prove very dry, you should give them a little water once a week, until they have taken root; after which they should be constantly kept clear from weeds, and the ground between the rows carefully dug every spring to loosen it, so as that the tender fibres may strike out on every side.

In this nursery they may continue one or two years, according to the progress they make; after which they should be transplanted where they are to remain, to produce fruit.

In removing these trees, you should observe to prune their downright roots, if they have any, pretty short, and to cut off all bruised parts of the roots, as also all the small fibres, which generally dry, and when left upon the roots after planting again, grow mouldy and decay, so that they are injurious to the new fibres which are shot out from the roots, and very often prevent the growth of the trees; but you should by no means prune their heads, for the plants which are produced from stones, are generally of a more spongy texture, and so more liable to decay when cut, than those which are budded upon other stocks. Besides, as these trees are designed for standards (for it is not proper to plant them against walls, until you see the produce of the fruit, to shew which of them deserves to be cultivated,) they will never require any other pruning, but only to cut out decayed branches, or such as shoot out very irregular from the sides, for more than this is generally very injurious to them.

In planting these trees, it will be the better way to dispose them singly in the quarters of the kitchen-garden, where they will thrive, and produce fruit much better than if they are planted near each other in rows; and, as they are thus singly disposed, they will not do much injury to the crops which grow under them.

When they have produced fruit, you will soon be a judge of their goodness, therefore such of them as you dislike may be destroyed; but those which are good, may be propagated by inoculating them upon other stocks, which is the common method now practised to propagate these fruits, therefore I shall now proceed to treat of that more particularly; in the doing of which, I shall set down the method now commonly practised by the nursery-gardeners, and then propose some few things of my own as an improvement thereon, for such persons who are very curious to have good fruit. But first,

You should be provided with stocks of the Muscle and white Pear Plums, which are generally esteemed the two best sorts of Plums for stocks to inoculate Peaches and Nectarines upon; as also some Almond and Apricot stocks, for some tender sorts of Peaches which will not grow upon Plum stocks. These should be all produced from the stone (as hath been already directed in the article NURSERY,) and not from suckers, for the reasons there laid down. These stocks should be transplanted, when they have had one year's growth in the seed-bed, for the younger they are transplanted, the better they will succeed, and hereby they will be prevented from sending tap-roots deep in the ground; for by shortening those roots which seem so disposed, it will cause them to put out horizontal roots. These stocks should be planted at the distance above-mentioned, viz. the rows three feet asunder, and one foot apart in the rows. This is wider than most nurserymen plant them, but I shall give my reasons hereafter for this.

When these stocks have grown in the nursery two years, they will be strong enough to bud; the season for which is commonly about Midsummer, or any time in July, when the rind will easily separate from

the wood, when you should make choice of some good cuttings of the sorts of fruit you intend to propagate, always observing to take them from healthy trees, and such as generally produce a good quantity of well-tasted fruit; for it is very certain, that any sort of fruit may be so far degenerated where this care is wanting, as not to be like the same kind. Besides, whenever a tree is unhealthy, the buds taken from that tree will always retain the distemper, in a greater or less degree, according as it hath imbibed a greater or less quantity of the distempered juice. Thus, for instance, where a Peach or Nectarine-tree hath been greatly blighted, so as that the shoots have grown busled, and the leaves curled up to a great degree, that distemper is seldom recovered again by the greatest art, or at least not under several years management; for let the seasons prove ever so favourable, yet these trees will continually shew the same distemper, which many persons are so weak as to suppose a fresh blight, whereas in reality it is no other but the remains of the former sickness, which are spread and intermixed with all the juices of the tree; so that whatever buds are taken from such trees, will always retain a part of the distemper.

Upon the care which is taken in the choice of the buds, the whole success depends; therefore a person who is curious to have good fruit, cannot be too careful in this particular; for in general no more is regarded by those nurserymen who are the most careful in propagating the several sorts of fruit-trees, than the taking their buds or grafts from the true kinds of fruit-trees; but there is still more care required to have sound healthy trees, especially in this of Peaches and Nectarines; for if the buds are taken from young plants in the nursery which have not produced fruit, the shoots of which are generally very strong and vigorous, these buds will have so vicious a habit, as rarely to be corrected and brought into good order; for they will shoot more like the Willow than the Peach, the joints being extended to a great distance from each other, the shoots very gross, and the wood pithy; therefore where the practice of taking the buds from nursery-trees is long continued, there can be little hopes of the trees so raised. I would therefore recommend it to every curious person, to procure their buds from such trees as have been long growing, whose fruit are well flavoured, and the trees perfectly sound; as also never to make choice of the strongest or most luxuriant shoots of these trees, but such shoots as are well conditioned, and whose buds grow pretty close together. And although these do not make so strong shoots the following years, as those which are taken from luxuriant branches, yet they will be better disposed to bear fruit, and will make much better trees.

The cuttings with which you are thus to be provided, should always be taken from the trees either in a morning or evening, or else in a cloudy day; for if they are cut off when the sun is very hot, the shoots will perspire so freely, as to leave the buds destitute of moisture, which is often the cause of their miscarrying; and the sooner they are put into the stocks when cut from the trees, the better they will take. The manner of this operation being fully explained under the article of INOCULATION, I shall not repeat it in this place. The management of these trees, during their remaining time in the nursery, is likewise fully set down under that article. I shall therefore proceed to give some directions for the choice of these trees, when they are to be procured from a nursery. The first care should be to find out a person of character to deal with, on whose integrity you may depend, not only for having the trees of those kinds which you propose, but also for their buds being taken from bearing trees; and either see them taken up, or let some person you can confide in do it for you; because, as most of the nurserymen have dealings with each other, if the person applied to has not the sort of fruit desired in his own nursery, he procures them from another; and if the gardener from whom

whom he gets them, is not as honest and careful as himself, it is a great chance if the trees prove to be of the right kinds.

The trees should also be chosen in the autumn, before others have drawn out the best; for those who go first to the nurseries, if they have skill, will always draw the finest plants. In the choice of the trees, you should observe the stocks upon which they have been budded, that they are of the right sort, whether Plum or Apricot; that they are sound and young, not such as had been budded the preceding year and failed, nor those which have been cut down. If the size of the stock is near that of a man's finger, it will be better than if they are larger; these should be clear of moss or canker. The buds should be of one year's growth only, and not such as have been cut down in the spring, and made a second shoot; nor should those trees be chosen whose shoots are very strong and luxuriant, but such as have clean shoots, of a moderate size, whose joints are not too far asunder; and those trees which stand on the outside rows, or near the ends of the rows, where they have most air, are generally such; for, where they stand close in the nursery, their shoots are drawn up in length, their joints are much farther asunder, and their buds or eyes are flat; for which reason, I have before advised the planting of the stocks at a greater distance than the nurserymen generally allow them; and, if a careful discreet nurseryman would be at the trouble and expence in the raising of his Peach-trees according to this method, he would better deserve three shillings per tree, than one in the manner they are usually raised; for every person who is at the expence of building walls for fruit, should not think of saving a few shillings in the purchase of their trees; because, if they are bad, or not of the right kinds, there is a great loss of time and expence to no purpose, and the disappointment will be so great, after waiting three or four years, as to discourage many from making farther trials, thinking themselves liable to the same ill success.

When the trees are chosen in the nursery, the next care must be to have them carefully taken up out of the ground, so as not to break or tear their roots, nor injure their bark; for as these trees are very apt to gum in those places where they are wounded, there cannot be too much care taken of this. If the trees are to be transported to a distant place, their roots should be closely wrapped either with haybands, straw, or Peas-haulm, and mats sewed over these, to prevent the air from drying their roots and branches. If the leaves of the trees are not fallen when they are taken up, they should be carefully stripped off, before the trees are packed up; for when there are many of these left, they are very apt to heat, if they are long in their passage, and often occasion a mouldiness very hurtful to the branches.

We come next to the preparing of the ground to receive the trees. The best earth for Peach-trees is such as is taken from a pasture-ground, that is neither too stiff and moist, nor over dry, but of a middling nature, such as is termed hazel loam. This should be dug from the surface of the ground about ten inches deep, taking the turf with it, and should be laid in heaps eight or ten months at least; but that which is prepared one year or more is still better before it be used, that it may have the winter's frost, and summer's heat to mellow it; during which time it should be often turned, to rot the turf and break the clods, whereby it will be rendered very light and easy to work; and about the beginning of September you should carry it into the garden, and make the borders, which must be raised in height proportionable to the moisture of the garden; but if the ground be very wet, it will be advisable to lay some rubbish in the bottom of the border to drain off the moisture, also to prevent the roots of the trees from running downward; and in this case it will be proper to make some under-ground drains at the bottom of the border, to convey off the superfluous moisture; which, if

detained about the roots of the trees, will greatly prejudice them; then raise a border of earth at least a foot, or in very wet land two feet above the level of the ground, so that the roots of the trees may always remain dry; but if the ground be pretty dry, the borders should not be raised above six or eight inches higher than the surface, which will be sufficient to allow for their sinking.

As to the breadth of these borders, that cannot be too great; but they should never be less than six or eight feet broad, where fruit-trees are planted, for when the borders are made very narrow, the roots of the trees will be so confined in four or five years time; that they will seldom thrive well after. The depth of these borders should not be greater than two feet and a half; for when they are prepared to a great depth, it only entices the roots of the trees downward, which may be the cause of their future barrenness; for their roots being got down below the influences of the sun and showers, imbibe a great quantity of crude juices, which only add to the luxuriant growth of the trees, and destroy their fruitfulness; besides, whatever fruit are produced from such trees, are not near so well tasted as those are which grow upon those trees whose roots lie near the surface, and enjoy the kindly benefit of the sun's heat, to correct and digest whatever crudities there may be in the earth.

Where the natural soil of the garden is shallow, and either chalk, clay, or gravel lies near the surface, these should not be dug out to make pits to receive the earth for the border, as is by some practised, for this will be no better than planting the trees in tubs or cases, for their roots will be confined to these pits; so that when they are extended to the sides, and can get no farther, the trees will blight and decay; and if it is clay on the sides, the wet will be detained as in a basin, and the earth of the border will be like mud in very wet seasons, so unfit for the roots of these trees. Therefore, whenever it so happens that the ground is of either of the sorts before-mentioned, it will be the best way to raise the borders of a proper thickness of good earth over these, rather than to sink down into them; for when the roots of the trees lie near the surface of the ground, they will extend to a great distance in search of nourishment; but if they get below the staple of the land, they can find nothing but sour crude pasture very unfit for vegetation.

Your borders being thus prepared, should lie about three weeks or a month to settle, by which time the season for planting will be come, which should be performed as soon as the leaves begin to decay, that the trees may put out new roots, before the frost comes on to prevent them. Your ground being ready, and the trees brought carefully to the place, the next work is to prepare them for planting, which is to be performed in the following manner: you must shorten all the roots, and cut off smooth and broken or bruised roots, as also all the small fibres should be taken off, for the reasons before given; and where any of the roots cross each other, the worst of them must be cut out, that they may not injure the other.

And having thus prepared your trees, you should measure out their distance, which ought never to be less than twelve feet; but where the ground is very good, they should be planted fourteen feet asunder. This I doubt not, will be thought too great a distance by many persons, especially since it is contrary to the general practice at this time; but I am satisfied whoever shall try the experiment, will find it no more than is sufficient for these trees where they are rightly managed; for if they take kindly to the soil, their branches may be so trained as to furnish all the lower part of the wall in a few years, which is what should be principally regarded, and not, as is too often the practice, run up the shoots in height, and leave all the lower part of the tree destitute of bearing wood, so that in a few years there will not be any fruit but upon the upper part of the trees; which also must be the case where they are planted too close, because there being no room to extend the branches on either side,

they are obliged to lead them upright, which produces the before-mentioned ill effect.

There may be also some persons, who may think this distance too small for these trees, because Plums, Cherries, and most other sorts of fruit-trees require much more room; but when it is considered, that Peach and Nectarine-trees produce their fruit only upon the former year's wood, and not upon spurs, as Cherries, Plums, and Pears do, so that the shoots of these trees must be annually shortened in every part of them to obtain bearing wood; therefore the trees may be kept in much less compass than those of any other sort of fruit, and thereby every part of the wall may be constantly supplied with bearing branches; for when the trees are planted at a great distance, the branches are often extended to such lengths as to leave the middle of the trees naked, for there are never any good shoots produced from the old branches of these trees.

And here I cannot help taking notice of another very great error in planting of wall-fruit, which is the placing standard or half standard trees between the others, to cover the upper part of the wall, and to produce fruit, until the trees underneath are grown up sufficient to furnish the walls, when the standards are to be taken away. This is done, without considering that the greater number of trees which are planted in a small compass, the less nourishment they can receive, and so consequently must be the weaker, for the same space of ground cannot nourish twenty trees equally as well as it could ten; so that whatever strength the standard-trees may have, the dwarfs will be proportionably weaker; and it is a common observation, that most trees extend their roots as far under ground, as their branches spread above ground; so that there should always be the same allowance given to the wall-trees, if we would have them strong and vigorous; therefore the building very high walls for fruit, unless for Pears, is to no purpose, for a ten or twelve feet wall will be sufficient for most sorts of fruit. I have seen gardens planted with fruit-trees by persons of great esteem for their skill in this art, where Peach and Nectarine-trees have been placed against walls exposed to the east and west, but could never see any of the fruit on those trees come to perfection; for which reason I would caution every person never to follow such examples, because it is well known, that the best aspected walls do barely ripen many of the latter Peaches some years; therefore the only aspect to which these trees should be exposed, is south, or with a point or two to the east, and some sorts may do well if they are a point or two to the west.

In the disposition of the trees, it will not be amiss to plant those sorts of Peaches near each other, which ripen about the same time; for by so doing, the fruit may be the better guarded from men and insects, and this will save a great deal of trouble in gathering of the fruit; for if a person is obliged to go from one part of the garden to the other, or perhaps to look over all the walls of the garden every time the fruit is gathered, it is a great loss of time, which may be avoided by this first care in planting the trees.

But to return to planting; after you have marked out the places where each tree is to stand, you must with your spade make a hole wide enough to receive the roots of the tree; then you should place it down, observing to turn the bud outwards, that the wounded part of the stock may be hid from sight; and let the stem of the tree be placed about four or five inches from the wall, with its head inclining thereto; then fill in the earth with your hands, observing to break the clods, that the earth may fall in between the roots, so as no void spaces may be left about them. You should also gently shake the tree with your hands, to settle the earth down the better between the roots; then with your foot gently press down the earth about the stem, but do not tread it down too hard, which is many times a very great fault; for when the ground is inclinable to bind, the treading it close doth often

render the ground so hard, as that the tender fibres of the roots cannot strike into it, whereby the tree remains at a stand for some time; and if the earth be not loosened in time, it frequently dies; so that whenever you observe the earth of your borders to be bound, either by great rains, or from any other cause, you should dig or fork it, to loosen it again, observing always to do it in dry weather, if in winter or spring; but in summer it should be done in a moist season.

Although I have here given directions for the choice of trees from the nursery, after the usual method of planting these trees, which is that of taking such as have made one year's shoot, yet I would prefer those which were budded the preceding summer, and have made no shoot; for if the bud is found and plump, and the bark of the stock well closed where the bud is inserted, there will be no danger of its growing; and when the bud has made a shoot the following spring the length of five or six inches, if it is stopped by pinching off the top, it will put out lateral branches, which may be trained to the wall, and this will prevent any cutting off the head, as must be done to those trees which have had one year's growth in the nursery; for these trees do not care for those large amputations, especially some of the more tender sorts; so by this method of planting these trees in bud, no time will be lost, when it is considered that the trees which have shot must be cut down, and there is a hazard of their shooting again; therefore I am convinced from experience, that it is the best method.

After you have thus planted your trees, which have made their shoots in the nursery, you should fasten their heads to the wall, to prevent their being shaken by the wind, which would disturb their roots, and break off the tender fibres soon after they were produced, to the no small prejudice of the trees; you should also lay some mulch upon the surface of the ground about their roots, before the frost sets in, to prevent it from penetrating the ground, which would injure, if not destroy, the small fibres; but this mulch should not be laid upon the ground too early, lest it prevent the autumnal rains from penetrating to the roots.

These things being duly observed, they will require no farther care till the beginning or middle of March, according as the season is earlier or later; when you must cut off the heads of the new planted trees, leaving only four or five eyes above the bud; in doing of which, you must be very careful not to disturb their roots; to prevent which, you should place your foot down close to the stem of the tree, and take fast hold of that part of the stock below the bud with one hand, to hold it steady, while with the other hand you gently slope off the head of the tree with a sharp knife at the intended place, which should always be just above a bud; this should always be done in dry weather, for if there should be much rain soon after it is done, there will be some danger that the wet will enter the wounded part, and damage the tree; nor should it be done in frosty weather for the same reason, for that would enter the wounded part and prevent its healing over. After you have headed the trees, you should gently loosen the earth of the borders, to admit the fibres of the roots; but you must be very careful in doing of this, not to cut or bruise their new roots, which would also damage them; and if the mulch which was laid about their roots in autumn be rotten, you may dig it into the border at some distance from the roots of the trees; and when the dry weather comes on, you should pare off some turf from a pasture ground, which should be laid upon the surface of the border about the roots of the trees, turning the Grass downward, which will preserve a gentle moisture in the earth, better than any other sort of mulch; and this will not harbour insects, as most sorts of dung and litter do, to the no small detriment of the trees.

Those trees which are planted in bud, and have not made any shoots, should have their stocks cut down

at this season just above the bud, for the buds will rarely shoot unless this is performed; and the nearer they are cut to the bud, the sooner will the head of the stock be covered by the buds; for although it may be necessary to leave a part of the stock above the bud, in those trees which are in the nursery, to which the shoots made by the buds may be fastened, to prevent their being broken by the wind; yet as these are placed against the wall, to which the shoots may be fastened, there will be no want of any part of the stock.

In watering these new planted trees, which should not be done unless the spring proves very dry, you should observe to do it with a nosse upon the watering-pot, so as to let it out in drops; for when it is hastily poured down, it causes the ground to bind; and if you water over the head of the tree, it will be of great service to it. Your waterings should not be repeated too often, nor should they be given in great quantity, both which are very injurious to new planted trees.

In the middle or latter end of May, when these trees will have several shoots six or eight inches in length, you should nail them to the wall, observing to train them horizontally, rubbing off all fore-right shoots, or such as are weak, whereby those which are preserved will be much stronger; but if there are not more than two shoots produced, and those very strong, you should at the same time nip off their tops, which will cause each of them to push out two or more shoots, whereby the wall will be better supplied with branches; you must also continue to refresh them with water in dry weather, during the whole season, otherwise they will be apt to suffer; for their roots having but little hold of the ground the first year after transplanting, if the season should prove very dry, it will greatly retard their growth, if due care be not taken to water them.

In the beginning of October, when you observe the trees have done shooting, you should prune them; in doing of which, you must shorten the branches in proportion to the strength of the tree; which, if strong, may be left eight inches long, but if weak, should be shortened to four or five; then you should train them horizontally to the wall (as was before directed,) so that the middle of the trees may be void of branches, for that part of the tree will be easily furnished with wood afterwards; whereas, if the shoots are trained perpendicularly to the wall, those which are the strongest, will draw the greatest share of the sap from the roots, and mount upwards; so that the side branches will be deprived of their nourishment and grow weaker, until they many times decay; and this is the reason that we see so many Peach-trees with one or two upright shoots in the middle, and the two sides wholly unfurnished with branches, whereby the middle of each tree cannot produce any fruit, that being filled with large wood, which never produces any bearing shoots. Nor can the two sides of the trees be regularly filled with fruitful branches, when this defect happens to them; therefore this method should be carefully observed in the training up young trees, for when they are permitted to run into disorder at first, it will be impossible to reduce them into a regular healthful state afterwards, the wood of these trees being too soft and pithy to admit of being cut down (as may be practised on many other hardy fruit-trees, which will shoot out vigorously again;) whereas these will gum at the places where they are wounded, and in a few years entirely decay.

The summer following, when the trees begin to shoot, you should carefully look over them, to rub off all fore-right buds, or such as are ill placed, and train those which are designed to remain horizontally to the wall, in their due order as they are produced, for this is the principal season when you can best order the trees as you would have them; whereas, if they are neglected until Midsummer, as is the common practice, a great part of the nourishment will be exhausted by fore-right shoots, and other useless branches, which must afterwards be cut off; and hereby the re-

maining shoots will be rendered very weak, and perhaps some part of the wall be entirely furnished with branches; which might have been easily supplied in May, by stopping some of the stronger shoots in such parts of the tree where there is a necessity for more branches, which would cause each of them to shoot out two or more side branches below the ends of the shoots, which may be guided into the vacant parts of the tree as they are produced, so as that every part may be regularly furnished with proper wood, which is the greatest beauty and excellency of wall-trees; but you should always forbear stopping the shoots in summer, where there is not a necessity for branches to fill the wall; for there cannot be a greater fault committed, than that of multiplying the number of shoots, so as to cause a confusion, whereby the branches will be too weak to produce good fruit; besides, when they are too close laid in against the wall, the air is excluded from the shoots by the great number of leaves, so that they are never duly ripened; and consequently, what fruit is produced thereon, cannot be so well tasted, as those which are produced upon such trees where the shoots receive all the advantages of the sun and air to bring them to maturity.

Thus having set down the method of training up young trees, I shall now proceed to their pruning and future management; which, being the same as with full grown trees, will serve for general directions how to manage these sorts of fruit.

In the pruning of Peach and Nectarine-trees (which require the same management) the two following rules should be strictly observed, viz. First, That every part of the tree be equally furnished with bearing wood; and secondly, That the branches are not laid in too close to each other for the reasons before laid down (with some others which will be hereafter inserted.) As to the first, it must be observed, That Peach and Nectarine-trees produce their fruit upon the young wood, either of the preceding year, or at most, the two years shoots, after which age they do not bear; therefore the branches should be shortened, so as to cause them to produce new shoots annually in every part of the tree; which cannot be done in the ordinary method of pruning, where persons neglect their trees at the proper season when they are most capable of management, which is in April, May, and June; at which time the luxuriant growth of branches may be checked by pinching, and new shoots produced where they are wanting, by stopping the neighbouring branches; which shoots, being produced at that season, will have time enough to ripen and gain strength before the autumn comes on; whereas all those shoots which are produced after the middle of June, will be crude and pithy; and though they may sometimes produce a few blossoms, yet those rarely bring fruit; nor are the future branches good which are produced from such wood, the vessels being too large to strain the juices, so that they easily admit of great quantities of crude nourishment to pass through them. Therefore those persons who only regard their wall-trees at two different seasons, viz. the winter and Midsummer pruning, cannot possibly have them in good order; for when all the branches which were produced in the spring, are permitted to remain until the middle or latter end of June (as is the common practice) some of the most vigorous will draw the greatest part of the nourishment from the weaker branches, which, when the strong ones are taken off, will be too weak to produce fair fruit; and hereby the strength of the tree is exhausted, to nourish the useless branches which are annually cut off again; and thus are too many trees managed, and at the same time complaints made of their luxuriance; because two or three shoots, by drawing away the greatest share of the nourishment grow very strong and woody (whereas, if the nourishment had been equally distributed to a regular quantity of branches, there would be no sign of their too great strength) until by often cutting off these vigorous branches, the trees are either entirely destroyed, or at least rendered so weak as not to be able

able to produce fruit; for although by thus weakening the branches, it is often the means to produce a good number of blossoms (as may many times be observed also upon autumnal shoots;) yet the utmost of their strength is spent in expanding the flowers, so that they rarely produce fruit; and very often the greatest part of the branches die soon after, which is supposed to be occasioned by a blight (as I have elsewhere said) when in reality it is nothing less than the fault of those who have the management of the trees. It is therefore of the greatest consequence to wall-trees, especially of these sorts, to go over them two or three times in the months of April, May, and June, to rub off all irregular shoots, and to train in the branches that are left in due order to the wall, that each shoot may have an equal advantage of sun and air, both of which are absolutely necessary to ripen and prepare the wood for the next year's bearing; therefore the oftener the trees are looked over, to divest them of the useless branches, from the time they first begin to shoot in the spring till the autumn, the better will the wood be ripened for the succeeding year. And by duly observing this in summer, there will not be occasion for so much cutting as is often practised on Peach-trees, to their great injury; for their wood branches are generally soft, tender, and pithy, which when greatly wounded, are not healed over again so soon as in many other sorts of trees; and the wet insinuating into the wounded parts, doth often cause the branches to canker and die; which may be entirely avoided by the gentle easy method of pinching and rubbing off the buds in the manner here directed, which makes no wounds on the tree; and hereby a vast deal of labour is saved, for one person who is ready at this business will go over a greater quantity of walling in one day, than three or four can when suffered to grow rude; so that if the trees are permitted to grow rude all the spring, they will require six times the labour to reduce them into order. Besides, it is a great disadvantage to the fruit, in permitting the branches of the trees to extend from the wall and shade them; and when they have grown under the shelter of these branches and leaves all the spring, until Midsummer, then by pruning off and shortening most of these shoots, and nailing the others close to the wall, the fruit are suddenly exposed to the sun and air, whereby they receive a very great check, and are not only retarded in their growth, but often rendered ill-tasted, and have tough skins. The distance which the branches of these trees should be allowed against the wall, must be proportioned to the size of the fruit or the length of the leaves; for if we observe how the branches of the trees are naturally disposed to grow, we shall always find them placed at a greater or less distance, as their leaves are larger or smaller, as I have already observed under the article LEAVES. And there is no surer guide to a curious artist than nature, from whence a gardener should always be directed in every part of his profession, since his business is to aid and assist nature, where she is not capable of bringing her productions to maturity; or where there is room, to make considerable improvements by art; which cannot be any otherwise effected, than by gently assisting her in her own way.

But to return to pruning these trees: the branches being carefully trained in, as before directed, in the spring and summer seasons, we come now to treat of the winter pruning, which is commonly performed in February or March. But the best season for this work is in October, when their leaves begin to fall, which will be early enough for their wounds to heal before the frost comes on, so that there will be no danger of their being hurt hereby; and the branches of the trees being proportioned to the strength of the roots at that season, all the ascending sap in the spring will be employed to nourish only those useful parts of the branches which are left; whereas, if they are left unpruned till February, the sap in the branches being then in motion, as may be observed by the

swelling of the buds, the greatest part of it will be drawn up to the extreme parts of the branches, to nourish such blossoms as must be afterwards cut off; and this may be easily known by observing the strongest shoots at that season, when you will find the extreme buds to swell faster than most of the lower ones; for there being no leaves then upon the branches to detain the sap to nourish the lower buds, the upper ones will always draw from those below.

But it is a constant practice amongst gardeners, founded upon long experience, to prune weak trees early in the winter, and luxuriant trees late in the spring, in order to check their luxuriance. Now it is evident, that this check does not proceed from any considerable loss of sap at the wounds of the pruned tree (excepting a few of the bleeding trees, when cut at that season) but must arise from some other cause; for by several experiments made by the Rev. Dr. Hales, in fixing mercurial gages to the stems of fresh cut trees, he found those wounds were constantly in an imbibing state, except the Vine in the bleeding season.

Therefore when a weak tree is pruned early in the beginning of winter, the orifices of the sap-vessels are closed up long before the spring; and consequently, when in the spring and summer, the warm weather advancing, the attracting force of the perspiring leaves is not then weakened by many inlets from fresh wounds, but is wholly exerted in drawing sap from the root; whereas, on the other hand, when a luxuriant tree is pruned late in the spring, the force of its leaves to attract sap from the root, will be much spent and lost at the several fresh cut inlets.

Besides, if it were no advantage to the trees to prune them at this season, (which I think no one will have reason to doubt after making the trial) but that it only succeeds as well as the spring pruning; yet there is a great advantage in doing it at Michaelmas, for that being a much more leisure season with gardeners than the spring, they will have more time to perform it carefully; and then they will not have so many things come together, which may require to be immediately executed; for the spring being the principal season for cropping their kitchen-gardens and attending their hot-beds, if they are disengaged from the business of pruning at that time, it will be of great advantage, especially where there is a great quantity of walling. And here is also another benefit in pruning at this season, which is, the having the borders at liberty to dig and make clean before the spring, so that the garden may not appear in a litter at that season.

Having said thus much concerning the time of pruning, I shall now proceed to give some general directions how it is to be performed on Peach and Nectarine-trees, which require a very different management from most other sorts of fruits.

In pruning these trees, you should always observe where branches are shortened, to cut them behind a wood-bud, which may be easily distinguished from the blossom-buds, which are shorter, rounder, and more turgid than the wood-buds; for if the shoot have not a leading bud where it is cut, it is very apt to die down to the next leading bud; so that what fruit may be produced above that, will come to nothing, there being always a necessity of a leading bud to attract the nourishment; for it is not sufficient to have a leaf-bud, as some have imagined, since that will attract but a small quantity of nourishment, the great use of the leaves being to perspire away such crude juices as are unfit to enter the fruit. The length you should leave these branches, should be proportioned to the strength of the tree, which, in a healthy strong tree, may be left ten or twelve inches, or more; but in a weak one, they should not be more than six inches; however, in this you must be guided by the position of a leading bud; for it is better to leave a shoot three or four inches longer, or to cut it two or three inches shorter than might be proper to do, provided there be one of these buds, it being absolutely necessary for the future welfare of the tree;

you

you should also cut out entirely all weak shoots, tho' they may have many blossom-buds upon them; for these have not strength enough to nourish the fruit, but they will weaken the other parts of the tree.

In nailing the shoots to the wall, you must be careful to place them at as equal distances as possible, that their leaves, when come out, may have room to grow without shading the branches too much; and you should never nail them upright if it can be avoided; for when they are thus trained, they are very subject to shoot from the uppermost eyes, and the lower part of the shoots will thereby become naked.

There is not any thing in the business of gardening, which has more exercised the thoughts of the curious, than how to preserve their tender sorts of fruit from being blighted in the spring of the year, and yet there has been little written upon this subject which is worth notice: some have proposed mattresses of straw or Reeds to be placed before the fruit-trees against walls, to prevent their being blasted; others have directed the fixing horizontal shelters in their walls, to prevent the perpendicular dew or rain from falling upon the blossoms of the fruit-trees, which they supposed to be the chief cause of their blighting; but both these contrivances have been far from answering the expectations of those persons who have put them in practice, as I have elsewhere shewn; therefore it may not be improper to repeat some things in this place, which I have before mentioned in relation to this matter. And

First, I have already said, that the blights which are so often complained of, do not so often proceed from any external cause, or inclemency in the season, as from a distemper or weakness in the trees; for if we observe the trees at that season, where they are the most subject to what is called a blight, we shall find the branches very small, weak, and not half ripened, as also trained in very close to each other; these branches are, for the most part, full of blossom-buds (which is chiefly occasioned by their want of strength.) These buds do indeed open, and to persons not skilled in fruit-trees, shew a great prospect of a plentiful crop of fruit; whereas the whole strength of the branches is spent in nourishing the flowers, and being unable to do any more, the blossoms fall off, and the small efforts of the leaf-buds are checked, so that many times great part of the branches die away, and this is called a great blight; whereas, at the same time it may be often observed, that some trees of a different sort, nay, even some of the same sort, were stronger and in health, though placed in the same soil, exposed to the same aspect, and subject to the same inclemency of air, have escaped very well, when the weak trees have appeared to be almost dead; which is a plain indication, that it proceeds from some cause within the tree, and not from any external blight. All this will therefore be remedied, by observing the foregoing directions in the pruning and management of the trees, so as never to over-burden them with branches, nor to suffer any particular part of the trees to exhaust the whole nourishment from the root, which will cause the other parts to be very weak; but to distribute the nourishment equally to every shoot, that there may be none too vigorous, at the same time that others are too weak; and by continually rubbing off useless or fore-right shoots as they are produced, the strength of the trees will not be spent, to nourish such branches as must be afterwards cut out, which is too often seen in the management of these trees. And

Secondly, It sometimes happens, that the roots of these trees are buried too deep in the ground, which, in a cold or moist soil is one of the greatest disadvantages that can attend these tender fruits; for the sap which is contained in the branches, being by the warmth of the sun, put strongly into motion early in the spring, is exhausted in nourishing the blossoms; and a part of it is perspired through the wood-branches, so that its strength is lost before the warmth can reach to their roots, to put them into an equal motion in

search of fresh nourishment, to supply the expence of the branches; for want of which, the blossoms fall off and decay, and the shoots seem to be at a stand, until the farther advance of the warmth penetrates to the roots, and sets them in motion; when suddenly after, the trees, which before looked weak and decaying, make prodigious progress in their shoots; and before the summer is spent, are furnished with much stronger branches than those trees which have the full advantage of sun and showers, and are more fruitful and healthy; which must certainly be owing to the cause here mentioned, as also to their drawing in a great quantity of crude moisture, which, though productive of wood, is yet unkindly for fruit: if therefore this be the case, there is no way of helping it, but by raising up the trees, if they are young; or if they are too old to remove, it is the better way to root them out and make new borders of fresh earth, and plant down young trees; for it is a great vexation to be at the trouble and expence of pruning and managing these trees, without having the pleasure of reaping any advantage from them, which will always be the case where the trees are thus injudiciously planted. Or,

Thirdly, This may proceed from the trees wanting nourishment, which is many times the case, where they are planted in a hard gravelly soil, in which it is the common practice to dig borders three or four feet wide, and three feet deep into the rock of gravel, which is filled with good fresh earth, into which the trees are planted, where they will thrive pretty well for two years, until their roots reach the gravel, where they are confined as if planted in a pot; and for want of proper nourishment, the branches continually decay every year. This cannot be helped where the trees have been growing some years, without taking them entirely up, or by digging away the gravel from their roots, and adding a large quantity of fresh earth, that may afford them a supply of nourishment a few years longer; but trees so planted, cannot by any art be continued long in health.

But if the unfruitfulness of the trees does not proceed from any of the before-mentioned causes, and is the effect of unkindly seasons, then the best method yet known is, in dry weather, when little dew falls, to sprinkle the branches of the trees gently with water soon after the blossoming season, and while the young-set fruit is tender, which should always be done before noon, that the moisture may evaporate before the night comes on; and if in the night you carefully cover the trees with mats, canvas, or some such light covering, it will be of great service to them: however, where the trees are strong and vigorous, they are not so liable to suffer by a small inclemency, as are those which are weak, so that there will be few seasons in which there may not be hopes of a moderate quantity of fruit from them, though there should be no covering used; for where these coverings are used, if it is not performed with great care and diligence, it is much better to have no covering, but to trust to the clemency of the season; for if the coverings are kept too close, or continued too long, the trees will receive more injury hereby, than from being constantly exposed; or, if after having been covered for some time, and then incautiously removed, so as to expose the trees too suddenly to the open air, they will suffer more thereby than if they had not been covered. However, I must repeat in this place what has been before mentioned under another article, of a management which has been generally attended with success, which is, the putting up two feather-edge deal boards joined together over the top of the trees, so as to form a pent-house to cast off perpendicular wet. These should be fixed up when the trees begin to blossom, and should remain till the fruit is well set, when they should be taken down to admit the dew and rain to the leaves and branches of the trees, which must not be longer kept off; and where the wall is long, and exposed to currents of wind, if at the distance of forty feet from each other, are fixed some cross Reed-

hedges, to project about ten feet from the wall, these will break the force of the wind, and prevent its destroying of the blossoms; and these may be removed away as soon as the danger is over. Where these things have been practised, they were generally attended with success; and as there will be no trouble of covering and uncovering in this method, after they are fixed up, there can be no danger of neglect, as very often is the case, when the trouble is great, or to be often repeated.

When your fruit is set, and grown to the bigness of a small nut, you should look over the trees and thin them, leaving them at least five or six inches asunder; for when they are permitted to remain in bunches, as they are often produced, the nourishment which should be employed wholly to the fruits designed to stand, will be equally spent amongst the whole number, a great part of which must be afterwards pulled off; so that the sooner this is done, the better it will be for the remaining fruit; and if it should sometimes happen, that a part of those left, by any accident, should be destroyed, yet the remaining ones will be much the larger and better tasted for it, and the trees will gain more strength, for a moderate quantity of fruit is always preferable to a great crop; the fruit when but few, will be much larger, better tasted, and the trees in a condition to bear well the succeeding year; whereas when they are overcharged with fruit, it is always small, ill tasted, and the trees are generally so much weakened thereby, as not to be in a condition for bearing well for two or three years after; so that upon the whole, it is much better to have a lesser number of fruit than is commonly esteemed a crop, than to have too many, since the fruit and also the trees are benefited thereby. The quantity of fruit to be left on large full-grown trees should never be greater than five dozen upon each; but on middling trees, three or four dozen will be enough.

If the season should prove hot and dry, it will be proper to draw up the earth round the stem of each tree, to form a hollow basin of about six feet diameter, and cover the surface of the ground in this basin with mulch; and once in a week or fortnight, according to the heat and drought of the season, pour down eight or ten gallons of water to the root of each tree; or where there is an engine which will disperse the water in gentle easy drops like rain, if the same, or a larger quantity of water is sprinkled all over the branches of the trees, and this, soaking down to the roots, will keep the fruit constantly growing, which will prevent their falling off the trees, as they generally do where this method is not practised; and the fruit being thus constantly nourished, will be much better tasted, and hereby the trees will be maintained in vigour; so that it is what I can from long experience recommend, as one of the most necessary things to be practised by all lovers of good fruit. But this should not be continued longer than while the fruit are growing, for afterward it will be hurtful to the trees and fruit, for a dry autumn ripens both wood and fruit better than a moist later season.

When the Peach-trees are carefully managed in the spring of the year, according to the rules before laid down, all the nourishment which the roots can supply will be usefully employed in nourishing such shoots only as are to be continued, as also the quantity of fruit which is proper for each tree, therefore both must of consequence be rendered better; for where there is not this care, the trees soon grow ragged, and are not furnished properly with branches; and those shoots which are produced, are some of them very weak, and others very luxuriant, whereby the trees are rendered very unsightly, as also unhealthy, and never continues many years fruitful; and by thus training the branches to the wall as they are produced, the fruit will be always exposed to the sun and air; which in the common method of managing these trees, by letting their branches grow rude all the spring, they are deprived from, and consequently do not receive the benefit from these equal to those

which are properly managed; and by the timely rubbing off useless and luxuriant shoots, it will save much trouble, and prevent the use of the knife in summer, which is very hurtful to these trees, for there will be no need to shorten any of the shoots in summer.

When these rules are duly executed, there will be no occasion to pull off the leaves of the trees, to admit the sun to the fruit, which is often practised; for if we consider, that the leaves are absolutely necessary to cherish the blossom-buds, which are always formed at the foot-stalks of the leaves, the pulling them off before they have performed the office assigned them by nature, is doing great injury to the trees, therefore I caution every one against that practice.

It is a common opinion which has for some years prevailed, even amongst persons of good understanding, that Peach-trees are not long lived, therefore should be renewed every twenty years; but this is a great mistake, for I have eaten some of the finest Peaches of various kinds, which grew on trees which had been planted above fifty years: and I am convinced by experience, that when the trees are budded upon proper stocks, and carefully planted and managed, they may be continued fruitful and healthy sixty years and upward; and the fruit produced on these old trees will be much better flavoured, than any of those upon young trees; but I suppose the foundation of the above opinion was taken from the French, who generally bud their Peaches upon Almond stocks, which are of short duration, these seldom lasting good more than twenty years; but this seldom being practised in England, the case is widely different; nor indeed should we fetch our examples from that nation, where the professors of the art of gardening are at least a century behind the English; and from their present disposition, seem unlikely to overtake them; for they depart from nature in almost every part of gardening, and are more pleased with introducing their little inventions of pruning and managing their fruit-trees, according to their own fancy, than they are careful to draw their instructions from nature, from whence the true art is to be obtained; so that in very few instances gardeners should deviate from nature, unless it be in those particulars, where art may be practised to the greatest advantage, which is in the procuring many sorts of esculent plants and fruits earlier and better flavoured than can be obtained without, in which the French are extremely deficient; and herein they trust too much to nature, and use too little art.

In one of the most celebrated of their authors, who treats very particularly of fruit-trees, there are directions for planting of Peach-trees twelve feet asunder, and at the same time he advises the planting of Pear-trees but nine or ten feet distance; and yet he says, that a Pear-tree in health will shoot three feet on each side every year; therefore he does not allow room for these trees to grow more than two years, before they meet. There is also another thing positively laid down by the same author, which is, never to lay any dung upon the borders where fruit-trees are growing, which, he says, will render the fruit ill tasted; and this opinion has too generally prevailed in England; but this hath been exploded by one of his own countrymen, who affirms, that from upward of twenty years experience, those trees where the borders had been constantly dunged, always produced the most delicious fruit, and the trees were in the greatest vigour; and the same gentleman mentions the practice of the gardeners at Montréuil near Paris, who have for some generations been famous for the culture of Peaches; and are as careful to dung the borders where their Peach-trees grow every other year, as the kitchen-gardeners are for their legumes.

And from a long experience it is, that I can subscribe to the truth of this; for in some particular gardens, where the best fruit grew that I have yet tasted, the ground was constantly dunged every other year; therefore it is what I must recommend to the practice of every curious person, with this caution, always to use such dung for their borders as is well rotted, and to dig

dig it into the borders in November, that the rain may wash down the salts before the spring comes on; and where the ground is very loose or sandy, it will be the best way to make use of neats dung, which is cooler than that of horses, but for cold strong land the latter is to be preferred.

If the ground is well trenched every year about the roots, it will be of great service to them; and where the soil is subject to bind very close, if it is forked two or three times in a year to loosen the surface, it will greatly help the trees. The borders should not be crowded with any large growing plants, which will draw away the nourishment from the trees; therefore when any sort of kitchen herbs are planted on these borders, they should be only such as are of small growth, and which may be taken off early in the spring; and if this is carefully observed, the cultivating small things on these borders can do no harm, because the ground will be stirred the oftener, on account of these small crops, than perhaps it would have been, when no use was to be made of the borders. These rules which are here laid down, if properly observed, will direct any curious person how to have plenty of good fruit, as also to preserve the trees in vigour a great number of years.

PERVINCA. See VINCA.

PETALS are the fine coloured leaves which compose the most conspicuous parts of a flower; these are called in Latin Petala, to distinguish them from the leaves of plants, which are called Folia.

PETASITES. See TUSSILAGO.

PETIVERIA. Plum. Nov. Gen. 50. tab. 39. Lin. Gen. Plant. 417. Guinea Henweed.

The CHARACTERS are,

The flower hath a permanent empalement, composed of five narrow obtuse leaves which are equal. It hath four small white petals, placed in form of a cross, which soon fall off, and six awl-shaped erect stamina terminated by single summits. In the center is situated an oblong compressed germen, with four awl-shaped styles, crowned by obtuse permanent stigmas. The germen afterward becomes one oblong seed, narrow at the bottom and taper, but broad above; where it is compressed and indented at the top, resembling an inverted shield armed with the acute style, which is reflexed.

This genus of plants is ranged in the fourth section of Linnæus's sixth class, which includes those plants whose flowers have six stamina and four styles.

The SPECIES are,

1. PETIVERIA (*Alliacea*) floribus hexandris. Hort. Cliff. 141. *Petiveria with six stamina in the flowers.* Verberna aut scorodonix affinis anomala, flore albido calyce aspero, alii odore. Sloan. Hist. 1. p. 171. commonly called Guinea Henweed.
2. PETIVERIA (*Ostandra*) floribus octandris. Lin. Sp. Plant. 486. *Petiveria with eight stamina in the flowers.* Petiveria solani foliis, loculis spinosis. Plum. Nov. Gen. 50.

The title of this genus was given to it by Father Plumier, who discovered it in America, in honour of Mr. James Petiver, an apothecary of London, who was a curious botanist.

The first is a very common plant in Jamaica, Barbadoes, and most of the other islands in the West-Indies, where it grows in shady woods, and all the savannas, in such plenty, as to become a troublesome weed; and as this plant will endure a great deal of drought, it remains green when other plants are burned up, which occasions the cattle to browse on it; and having a most unsavoury strong scent, somewhat like wild Garlick, it gives the cows milk the same flavour, and the cattle which are killed soon after feeding on this plant, have a most intolerable scent, and their flesh is good for little. The roots are strong, and strike deep in the ground; the stalks rise from two to three feet high; they are jointed and become lignedus at bottom, and are garnished with oblong leaves three inches long, and an inch and a half broad, of a deep green, and veined; these are placed alternately upon short foot-stalks. The flow-

ers are produced in slender spikes at the end of the branches; they are very small, so make no figure. They appear in June, and are succeeded by short seed-vessels shaped like an inverted shield, containing one oblong seed which ripens in the autumn.

The second sort is very like the first, from which it differs in having a shorter and narrower stalk, and the flowers having eight stamina; but unless these marks are distinguished by a nice observer, they may both pass for one plant.

In Europe, these plants are preserved in the gardens of those persons who are curious in botany; but they have little beauty, and having so strong rank scent upon being handled, renders them less valuable. They are propagated by seeds, which must be sown on a hot-bed early in the spring, and when the plants are come up, they should be each transplanted into a separate pot, and plunged into a moderate hot-bed to bring them forward. When the plants have obtained a good share of strength, they should be inured to bear the open air by degrees, into which they may be removed toward the latter end of June, placing them in a warm situation, where they may remain till autumn, when they should be removed into the stove, and in winter must have a moderate degree of warmth, otherwise they will not live in this country.

They will produce flowers and seeds every summer, and will continue several years, remaining constantly green throughout the year, and may be propagated by slips or cuttings.

PETREA. Houst. Gen. Nov. Lin. Gen. Plant. 682.

The CHARACTERS are,

The flower hath a bell-shaped empalement of one leaf, cut into five large obtuse segments almost to the bottom, which are coloured, expanded and permanent. The flower hath one petal, having a short tube, but is cut above into five almost equal segments, which are expanded. It hath four short stamina situated in the tube, two of which are a little longer than the other, terminated by single summits, and four germen supporting a slender style, crowned by an obtuse stigma. The germen afterward become four seeds wrapped up in a fringed cover.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, which includes those plants whose flowers have two long and two shorter stamina, and the seeds are inclosed in a cover.

The title of this genus was given to this plant by the late Dr. Houstoun, who discovered it growing naturally at La Vera Cruz in New Spain, in honour of Lord Petre, who was a great encourager of botany, and was possessed of a noble collection of exotic plants.

We have but one SPECIES of this genus, viz.

PETREA (*Clusilis*) frutescens foliis lanceolatis rigidis, flore racemoso pendulo. *Shrubby Petrea with stiff spear-shaped leaves, and flowers growing in long hanging bunches.*

This plant was first discovered by the late Dr. Houstoun, growing naturally at La Vera Cruz in New Spain, in 1731, since which time it was sent me from the island Barbuda, where it also grows naturally. It rises with a woody stalk to the height of fifteen or sixteen feet, which is covered with a light gray bark, sending out several long branches; these have a whiter bark than the stem, and are garnished with leaves at each joint, which on the lower part of the branches are placed by threes round them, but higher up they stand by pairs; they are about five inches long, and two inches and a half broad in the middle, drawing to a point at each end; they are stiff, and their surface rough, of a light green, having a strong dark midrib, with several transverse veins running from the midrib to the borders, which are entire. The flowers are produced at the end of the branches growing in loose bunches, which are nine or ten inches long, each flower standing upon a slender foot-stalk about an inch long; the empalement of the flower is composed of five narrow obtuse leaves about an inch long, which are of a fine blue colour, so are much more conspicuous than the petals, which are white;

white, and not more than half the length of the empalement. After the flower is past, the four germen in the center become so many oblong seeds wrapped up in a fringed cover.

The Doctor found a variety of this with blue petals, of the same bright colour with the empalement, which made a fine appearance, every branch being terminated by a long string of these flowers, so that he has ranked this among the first class of beautiful American trees.

So far as I have been able to discover from the dried samples which the Doctor brought to England, it appears that there are male and female flowers either on different parts of the same tree, or upon different trees; for one spike of flowers seems to be entirely male, and the other spikes are female, but the Doctor has not noticed this in his manuscript.

This is propagated by seeds, which must be obtained from the places where the trees grow naturally, and these are very few good; for, from the seeds which the Doctor sent to England, there were but two plants raised, though the seeds were distributed to several persons; and this is a sort of confirmation of the spikes of flowers being of different sexes, and that the seeds gathered by the Doctor, were taken either from trees at some distance from the male, or such parts of the same tree which were remote from the male flowers. The seeds must be sown in a good hot-bed, and when the plants come up, they should be each planted in a separate small pot filled with light loamy earth, and plunged into a hot-bed of tanners bark, and afterwards placed in the bark-bed in the stove, where they should constantly remain, and be treated like other plants of the same country.

PETROSELINUM. See APIUM.

PEUCEDANUM. Tourn. Inst. R. H. 318. tab. 169. Lin. Gen. Plant. 302. Hogs-fennel, or Sulphur-wort.

The CHARACTERS are,

It hath an umbelliferous flower. The principal umbel is composed of several long narrow umbels which spread open. The cover of the large umbel is composed of many linear reflexed leaves. The empalement of the flower is small and indented in five parts. The petals of the great umbel are uniform. Each flower is composed of five oblong incurved petals, which are equal and entire; they have each five hair-like stamina, terminated by single summits, with an oblong germen situated under the flower, supporting two small styles, crowned by obtuse stigmas. The germen afterward turns to an oval fruit channelled on each side, splitting in two parts, containing two seeds convex on one side, compressed on the other, with three raised furrows, and a broad membranaceous border indented at the top.

This genus of plants is ranged in the second section of Linnæus's fifth class, which includes the plants whose flowers have five stamina and two styles.

The SPECIES are,

1. PEUCEDANUM (*Officinale*) foliis quinquies tripartitis linearibus. Lin. Sp. Plant. 358. *Hogs-fennel with leaves which are divided by fives, and these are again divided into three linear segments. Peucedanum Germanicum. C. B. P. 149. German Hogs-fennel.*
2. PEUCEDANUM (*Italicum*) foliis tripartitis filiformibus longioribus, umbellis difformibus. *Hogs-fennel with leaves cut into three parts, which are longer, slender, and have irregular umbels. Peucedanum majus Italicum. C. B. P. 149. Greater Italian Hogs-fennel.*
3. PEUCEDANUM (*Alpestre*) foliolis linearibus ramosis. Hort. Cliff. 94. *Hogs-fennel with leaves branching, which are very slender. Ferula foliis libanotidis brevioribus, alpestris, umbellis amplissimis. Boerh. Ind. alt. 1. p. 65.*
4. PEUCEDANUM (*Minus*) foliis pinnatis, foliolis pinnatifidis, laciniis linearibus oppositis, caule ramosissimo patulo. Flor. Angl. 101. *Hogs-fennel with winged leaves whose cuts are linear and opposite, with a spreading branching stalk.*
5. PEUCEDANUM (*Nodosum*) foliolis alternatim multifidis. Hort. Cliff. 94. *Hogs-fennel with many-pointed*

leaves placed alternately. Silaum (quod ligusticum Creticum, foliis fœniculi caule nodoso. Tourn. Cor. 23.)

The first sort is said to grow naturally in England, but I have not been lucky enough to find it, though I have searched the places where it is mentioned, but it grows in several parts of Germany in marshy meadows. This hath a perennial root, which divides into many strong fibres running deep in the ground, from which arise the foot-stalks of the leaves which are channelled; these are naked at bottom, but about four or five inches from the root branches into five smaller foot-stalks, and these again divide into three, and each of these divisions sustain three narrow leaves, which when bruised emit a strong scent like sulphur. The stalks rise near two feet high; they are channelled, and divide into two or three branches, each being terminated by a large regular umbel of yellow flowers, composed of several small umbels which are circular. These flowers appear in June, and are succeeded by compressed seeds, which are deeply furrowed, and ripen in the autumn.

The second sort grows naturally on the mountains, and also in the low valleys by the sides of rivers in Italy. The root of this is perennial, striking deep into the ground; the foot-stalks of the leaves are large and furrowed, dividing into three small branches, which are again divided into three, and these end with three long narrow lobes or small leaves, which are much longer than those of the other sort. The stalks which sustain the umbels rise near three feet high, and divide toward the top into several small branches, each sustaining an umbel composed of several smaller rays or umbels, which stand upon very long foot-stalks, that spread out irregularly. The flowers of this are yellow, and shaped like those of the former, but are much larger, as are also the seeds, but have the same form as the other. It flowers and perfects seeds about the same time as the former.

The third sort grows naturally in the forest of Fontainebleau, and some other parts of France; it hath a perennial root, from which come out leaves which branch into several divisions, that divide again into smaller; each of these smaller divisions are garnished with five short narrow leaves. The stalks are round, and not so deeply channelled as either of the former, sustaining a large umbel of yellow flowers shaped like those of the former sorts; the seeds are shorter, but of the same shape as those. It flowers in June, and the seeds ripen the beginning of September.

The fourth sort grows naturally on St. Vincent's rock near Bristol; this is a biennial plant, which perishes soon after it has perfected its seeds. The leaves of this sort are short and very narrow, spreading near the surface of the ground; the stalks rise near a foot high, but are branched almost from the bottom; these branches are almost horizontal, and are garnished with a few narrow short leaves of a lucid green. Each stalk is terminated by a small umbel of flowers, which are of an herbaceous yellow colour and small. These are succeeded by small channelled seeds.

The fifth sort grows naturally in Crete; it is not a plant of long duration in England, nor do the seeds ripen well here. The stalks rise a foot and a half high, having pretty large knots at the joints, from which arises a leaf cut into many divisions; the flowers terminate the stalks in umbels, and appear the beginning of July, and in warm seasons the seeds will ripen in the autumn.

The first sort stands in the list of medicinal plants, but is at present rarely used; the roots are the only part prescribed. It is accounted good to clear the lungs of tough viscid phlegm, and thereby to help old coughs and shortness of breath; it likewise opens obstructions of the liver and spleen, and helps the jaundice.

The other sorts are preserved in botanic gardens for the sake of variety; they are all propagated by seeds, which should be sown in the autumn soon after they are ripe, for those which are sown in the spring seldom

dom succeed, or if the plants come up, it is rarely before the following spring. When the plants come up, they must be kept clean from weeds, and the autumn following they may be transplanted where they are to remain; they love a moist soil and a shady situation, but will not thrive under the drip of trees. The roots of the three first sorts will continue several years, and every year produce flowers and seeds. The fourth sort will rarely ripen seeds in a garden, so that I have been obliged to procure them from the place where it grows naturally.

PHACIA. Lin. Gen. Plant. 798. Astragaloides. Tourn. Inst. R. H. 399. tab. 223. Bastard Milk-vech, or Astragaloides.

The CHARACTERS are,

The flower hath a tubulous empalement of one leaf, which is cut into five small indentures at the brim. It is of the butterfly kind, having a large, oval, erect standard, with two oblong wings shorter than the standard, which are obtuse, and a short compressed obtuse keel. It hath ten stamina, nine of which are joined in one body, and the other stands separate, terminated by roundish rising summits. In the center is situated an oblong germen, supporting an awl-shaped style, crowned by a single stigma. The germen afterward becomes an oblong swelling pod, whose upper suture is depressed toward the under, having one cell, containing several kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. PHACA (*Batica*) caulescens erecta pilosa, leguminibus tereti-cymbriformibus. Lin. Sp. Plant. 755. Phaca with a hairy upright stalk, and taper boat-shaped pods. Astragaloides Lusitanica. Tourn. Inst. R. H. 399. Portugal Bastard Milk-vech.

2. PHACA (*Alpina*) caulescens erecta glabra, leguminibus oblongis inflatis subpilosis. Lin. Sp. Plant. 1064. Phaca with an upright smooth stalk, and oblong, swelling, hairy pods. Astragaloides elatior erecta, vicæ foliis, floribus luteis, siliquis pendulis. Amman. Ruth. 148. Taller upright Milk-vech, with a Vetch leaf, yellow flowers, and pendulous pods.

The roots of the first sort which grows naturally in Spain and Portugal, will abide many years, and run very deep into the ground, but the branches decay every autumn; these commonly rise near four feet high, and become ligneous. The flowers are produced in short spikes from the wings of the leaves, but unless the season proves very warm, they rarely flower in England, for which reason the plants are not much esteemed; for it is not once in seven years that the flowers arrive to perfection, nor do the plants ever produce seeds in England; so that the seeds must be procured from abroad, by those who are desirous to have the plants.

The second sort hath smooth stalks, which do not rise so high as the former; the flowers are smaller, the pods are much shorter, and hang downward.

Both these sorts are propagated by seeds; those of the first should be sown in the place where the plants are to remain; for as the roots strike very deep into the earth, so it is very difficult to transplant them with any safety, especially after they have remained any considerable time in the seed-bed. The plants should be left about six feet asunder, that there may be room to dig the ground between them every spring, which is all the culture they require, except the keeping them clean from weeds.

The second sort produces flowers in two years from seeds, and the seeds ripen well in England, but the roots rarely live longer than three or four years.

PHALANGIUM. See ANTHERICUM.

PHALARIS. Lin. Gen. Plant. 74. Canary Grass.

The CHARACTERS are,

It is one of the Grass tribe, with one flower inclosed in a calyx, having two valves, which is boat-shaped and compressed; the flower is less than the cup, the outer valve is oblong and twisted, the inner is smaller. It has

three hair-like stamina, terminated by oblong summits, and a roundish germen supporting two hair-like styles, crowned by hairy stigmas; the seeds are inclosed by the petals of the flower, each containing one smooth seed pointed at each end.

This genus of plants is ranged in the second section of Linnæus's third class, intitled Triandria Digynia, the flowers having three stamina and two styles.

The SPECIES are,

1. PHALARIS (*Canariensis*) panicula subovata spiciformi, carinatis glumis. Lin. Sp. Plant. 79. Canary Grass with oval spike-shaped panicles, and boat-shaped chaff. Phalaris major femine albo. C. B. P. 28. Canary Grass with a white seed.

2. PHALARIS (*Arundinacea*) panicula oblonga ventricosa. Lin. Sp. Plant. 80. Reed-like Canary Grass, with an oblong bellied panicle. Gramen arundinaceum, acerola gluma, Jerseianum. D. Sher.

There are several species of this genus which are never cultivated for use, therefore it would be to little purpose to enumerate them here.

The first sort is cultivated in some parts of England, particularly in the isle of Thanet in Kent, where this is esteemed as a profitable crop, and may be so to those who are situated where they have water carriage for the seed to the London markets, where is the general demand for this commodity. About London there is very little of it sown, and what is there cultivated is chiefly by some few curious persons, in small quantities, for their amusement. I have several years sown some of this seed by way of trial, but have never seen more than a few rods of ground sown with it, therefore cannot give so good an account of its culture as I could wish; however, I shall briefly give an account of the success I have had in those trials which I have made on this plant.

The first experiment I made was by sowing of the seed in broad cast all over the ground, and as the land was very poor, I sowed the seeds too thick, which is the common fault of farmers in general; the seeds grew well, but the months of May and June proving wet, the plants grew tall, and having weak tender stalks, a heavy rain which fell the beginning of August laid it flat on the ground, and many succeeding showers which happened after kept it down, so that the whole crop was lost.

The following year I sowed a spot of ground with this seed in rows at a foot distance, but the seeds were sown too thick in the drills, so that the plants were drawn up so weak, that great part of these were lodged by wet in the month of August; but many of the outside plants in the drills, whose stalks were much stronger than those of the other, remained upright, so produced a good quantity of seeds which ripened well. This put me on making a farther trial of this plant; accordingly I sowed the seeds thin, in drills made a foot asunder, and when the plants came up, where they were too close I thinned them, so as to leave them near two inches distance in the rows; and the season proving favourable, the plants sent out many stalks from the roots, which were strong, so able to bear up till the seed was perfectly ripened; and by hoeing the ground three times in the intervals, the weeds were destroyed, and the ground kept clean; the crop also was so plentiful, as to assure me that the culture of this plant would answer well to the farmer, provided a sufficient quantity of seed was demanded; but as there is but a moderate sale for the seeds, and that being chiefly in London, so the culture of this plant would not answer to those who are situated at a distance from the metropolis, or who had not water carriage for the seeds thither.

From several trials since made, I find that three gallons of the seed is sufficient to sow an acre of land; and if the seed is sown by a hopper, whose spring is properly set, to let out the seed at equal distance, it will be the best method of cultivating it, and keeping the ground clean from weeds, will not only improve the crop, but also be of great advantage to the future crops.

When the seed is ripe it should be immediately cut, otherwise a good quantity will soon shed out; and if it is turned two or three times to dry, according to the favourableness of the season, it will be fit to thrash out the seed, and the sooner that is done, the less loss there will be of the seed.

PHASEOLOIDES. See GLYCINE.

PHASEOLUS. Tourn. Inst. R. H. 412. tab. 232. Lin. Gen. Plant. 777. [takes its name of *φάσολα*, an oblong swift ship, because the husk of this plant resembles a ship.] Kidney-bean; in French, *Haricot*.

The CHARACTERS are,

The empalement of the flower is of one leaf, having two lips; the upper lip is indented at the top, and the under one is divided in three parts. The flower is of the butterfly kind; it hath a heart-shaped, obtuse, inclined standard, reflexed on the sides; the wings are oval, the length of the standard, and a narrow spiral keel twisted contrary to the sun. It hath ten stamina, nine joined in one body, and the other standing separate, which are spiral within the empalement, terminated by single summits, and an oblong, compressed, hairy germen, supporting a slender, inflexed, spiral style, crowned by an obtuse hairy stigma. The germen afterward becomes a long pod with a thick shell, ending in an obtuse point, inclosing oblong, compressed, kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnaeus's seventeenth class, which contains those plants whose flowers have ten stamina joined in two bodies; he has divided the plants which were formerly included in this genus into two genera, one of which he calls *Dolichos*, and the other *Phaseolus*; the latter differs from the former, in having the parts of generation in the flowers spirally twisted.

It would be to little purpose to enumerate all the varieties of this plant which have come to our knowledge in this place, since America does annually furnish us with so many new sorts, as that there is no knowing what varieties there may be produced in different countries: besides, as they are not likely to be much cultivated here, since some of the old sorts are preferable to any of the new, for the use of the kitchen-garden, therefore I shall only first mention a few sorts which are cultivated for their flowers, or as curiosities, and then mention those which are most esteemed for the table.

The SPECIES are,

1. PHASEOLUS (*Alatus*) volubilis, floribus laxè spicatis, alis longitudine vexillo. Lin. Sp. Plant. 1017. Kidney-bean with a twining stalk, and flowers growing in loose spikes, whose wings are as long as the standard. Phaseolus flore purpureo, alis amplis longè protensis. Hort. Elth. 314. tab. 235. Kidney-bean with a purple flower, having large wings which are stretched out to a great length.
2. PHASEOLUS (*Caracalla*) volubilis, vexillis carinâque spiraliter convolutis. Lin. Sp. Plant. 1017. Kidney-bean with a twining stalk, whose standard and keel are spirally twisted. Phaseolus Indicus cochleato flore. Triumph. Obs. 93. Indian Kidney-bean with a snail-shaped flower, commonly called *Caracalla* in Portugal.
3. PHASEOLUS (*Vexillatus*) volubilis, vexillis revolutis patulis leguminibus linearibus strictis. Lin. Sp. Plant. 1017. Kidney-bean with a twining stalk, a spreading standard which is twisted backward, and narrow close pods. Phaseolus flore odorato, vexillo amplo patulo. Hort. Elth. 313. Kidney-bean with a sweet flower, having a large spreading standard.
4. PHASEOLUS (*Farinosus*) volubilis pedunculis subcapitatis, seminibus tetragono-cylindricis pulverulentis. Hort. Upsal. 214. Kidney-bean with a twining stalk, foot-stalks ending in flowers growing in heads, and four-cornered cylindrical dust-coloured seeds. Phaseolus peregrinus, flore roseo, semine tomentoso. Nissol. Act. Pat. 1730. Foreign Kidney-bean with a Rose-coloured flower and downy seeds.
5. PHASEOLUS (*Vulgaris*) volubilis, floribus racemosis geminis, bracteis calycè minoribus, leguminibus pendulis. Lin. Sp. Plant. 724. Kidney-bean with a twining

stalk, branching flowers growing by pairs, bractea which are shorter than the empalement, and hanging pods. Phaseolus Indicus, flore coccineo sive puniceo. Mor. Hist. 2. p. 69. Indian Kidney-bean with a scarlet or purple flower, commonly called the *Scarlet-bean*.

6. PHASEOLUS (*Coccineus*) volubilis, floribus racemosis, filiquis brevibus pubescentibus. Kidney-bean with a twining stalk, flowers growing in long bunches, and short hairy pods. Phaseolus florum spicâ pyramidarâ, semine coccineo nigra maculâ notatâ. Plum. Cat. 12. Kidney-bean with flowers growing in a pyramidal spike, and scarlet seeds which are marked with black.

The first sort is an annual plant; the seeds of this were brought from Carolina, where it grows naturally. The stalks of this twine about any support like the common Kidney-bean; they are hairy, and rise four or five feet high; the leaves are shaped like those of the common Kidney-bean, but are narrower. The flowers are produced in loose spikes, standing upon long foot-stalks; they are large and of a purple colour, turning to a blue before they fade. These appear in July, and if the autumn proves warm, they will be succeeded by narrow long pods, containing small oval seeds which ripen in October.

The seeds of this sort should be sown on a warm border about the latter end of April, and when the plants begin to run up, they must be supported either with sticks, or fastened to a hedge or wall, to prevent their trailing on the ground, and constantly kept clean from weeds. If they are close to a wall or hedge exposed to a good aspect, they will ripen their seeds in England, otherwise they frequently fail in bad seasons.

The second sort grows naturally in the Brazils, from whence the seeds were brought to Europe. This is a perennial plant with twining stalks, which rise to the height of twelve or fourteen feet; the leaves are shaped like those of the common Kidney-bean, but are smaller. The flowers are produced in slender spikes; they are of a purplish colour, and have an agreeable odour; these are succeeded by slender pods which are compressed, containing several oval compressed seeds. This is propagated by seeds, which should be sown in a moderate hot-bed in the spring; and when the plants come up, they must be carefully transplanted into pots filled with light fresh earth, and must be plunged into a hot-bed to facilitate their taking root; after which they should be inured to bear the open air by degrees, into which they should be removed the end of June or beginning of July, placing them in a sheltered situation; and as they advance in their growth, and fill the pots with their roots, they should be removed into larger pots, which must be filled with fresh light earth.

During the summer season they must be frequently refreshed with water; but in winter they must be removed into the green-house, and should have but little water during that season. These plants when young, are tender, but after the first winter they will require only to be screened from frost, but must have open free air whenever the weather will permit, otherwise the leaves will grow mouldy, and decay the tender shoots. This plant produces its flowers in July and August, but seldom perfects its seeds in England. It is very common in Portugal, where the inhabitants plant it to cover arbours and seats in gardens, for which it is greatly esteemed by the inhabitants of that country, for its beautiful sweet-smelling flowers, and in that country it thrives very well in the open air.

The third sort grows naturally in America, and is preserved in some curious gardens for variety, but is a plant of no great beauty; this may be propagated by sowing the seeds in the spring upon a hot-bed, and when the plants come up, they must be planted in pots, and treated as the former sort. It produces its flowers in July, and the seeds ripen in September. The fourth sort was brought from America, and is preserved in curious gardens for the sake of its long flowering. This is an abiding plant, and should be managed as was directed for the third sort, but this requires

requires a stove to preserve it through the winter in England.

The fifth sort has been long cultivated in the English gardens for the beauty of its scarlet flowers; this hath twining stalks, which, if properly supported, will rise to the height of twelve or fourteen feet; the leaves are smaller than those of the common Kidney-bean. The flowers grow in large spikes, and are much larger than those of the common Kidney-bean, and of a deep scarlet colour; the pods are large and rough, and the seeds are purple marked with black. This sort requires no other treatment than the common sort, but the stalks should have tall stakes put down by them to twine round, otherwise they will fall on the ground, which will soon cause them to rot.

Although this sort is chiefly cultivated for the beauty of its flowers at present, yet I would recommend it as the best sort for the table; and whoever will make trial of this, I dare say must prefer it to all the other kinds yet known.

The fifth sort grows naturally in the warmest part of America, so will not thrive in England out of a stove; and as the chief beauty of it is in the seeds, which are half scarlet and the other half black, so these may be procured from abroad better than raised here.

I shall now mention those sorts of Kidney-beans which are cultivated in the English gardens to supply the table, which are few in comparison of the number already known, though these are not many of them valuable, and are only cultivated because they require less care, or will come a little forwarder in the season, for they are inferior in taste to the others; however, as there are some persons who esteem them for their qualities before-mentioned, so I shall put them down in the order of their ripening for use.

The three sorts which are usually cultivated for early crops, are the small white Dwarf, the Dwarf black, which is called the Negro-bean, and the Liver Colour Bean. The stalks of these are never very long, so may be planted much nearer together than the larger growing kinds, and they require but little support; so these are planted on hot-beds under frames, or in pots which are placed in stoves, to come early in the spring, for which purpose they are better adapted than any of the other; but they are not to be compared with some of the others for goodness; but as they may be had at a time when the others cannot be so well obtained, so they are generally cultivated in the gardens; and where there are not the convenience of stoves or frames for raising them very early, they are planted in warm borders near hedges, walls, or pales, where they will be fit for use a fortnight earlier than the other sorts.

The next to these are the Battersea and Canterbury Kidney-beans; these do not ramble far, and produce their flowers near the root, so bear plentifully for some time: the Battersea Bean is the forwarder of the two, but the other will continue bearing much longer; they are both better flavoured than either of the three former sorts, but when they begin to be large are very stringy and tough.

There are two or three sorts of Kidney-beans cultivated with erect stalks, which want no support, as they do not put out any twining stalks; these are much cultivated by the gardeners for that reason, as also for their producing a great plenty of pods; but they are inferior in goodness to all the other, especially that sort with black and white seeds, whose pods have a rank flavour, and, when boiled, become soft and mealy; so this should never be propagated by persons of taste.

The best sorts for the table are the scarlet Blossom-bean before-mentioned, and a white Bean of the same size and shape, which appears to be only a variety of the scarlet, as it differs in no other respect but the colour of the flowers and seeds, being equal in size and flavour. And next to these is the large Dutch Kidney-bean, which grows as tall as either of these, so must be supported by stakes, otherwise their stalks

will trail upon the ground and spoil. The sort with scarlet flowers is preferable to this in goodness, and is also hardier; and although it will not come so early as some of the dwarf kinds, yet as it will continue bearing till the frost puts a stop to it in the autumn, so it is much preferable to either of them; for the pods of this sort when old, are seldom stringy, and have a better flavour than the young pods of those sorts, and will boil greener; and where this is sown in the same situation and soil as the Battersea-bean, it will not be a fortnight later.

All the sorts of Kidney-beans are propagated by seeds, which are too tender to be sown in the open air before the middle of April; for if the weather should be cold and wet after they are in the ground, they will soon rot; or if the morning frosts should happen after the plants come up, they will be destroyed; therefore the best way to have early Kidney-beans, where there is no conveniency of frames for raising them, is to sow the seeds in rows pretty close upon a moderate hot-bed, the latter end of March, or the beginning of April. If the heat of the bed is sufficient to bring up the plants, it will be enough; this bed should be arched over with hoops, that it may be covered with mats every night, or in bad weather. In this bed the plants may stand till they have put out their trifoliate leaves, then they should be carefully taken up, and transplanted in warm borders near hedges, pales or walls. If the season proves dry at the time of removing them, the plants should be gently watered to forward their taking new root, and afterward they must be managed in the same way as those which are sown in the full ground. These transplanted Beans will not grow so strong as those which are not removed, nor will they continue so long in bearing, but they will come at least a fortnight earlier than those which are sown in the full ground.

The first crop intended for the full ground, should be put in about the middle of April; but these should have a warm situation and a dry soil, otherwise the seeds will rot in the ground; or if the weather should prove so favourable as to bring up the plants, yet there will be danger of their being killed by morning frosts, which frequently happen the beginning of May.

The second crop, which should be one of the three large sorts last mentioned, should be sown about the middle of May. These will come into bearing before the early kinds are over, and if they are of the scarlet sort, will continue fruitful till the frost destroys the plants in the autumn, and these will be good as long as they last. The manner of planting them is to draw shallow furrows with a hoe, at about three feet and a half distance from each other, into which you should drop the seeds about two inches asunder; then with the head of a rake draw the earth over them, so as to cover them about an inch deep.

If the season is favourable, the plants will begin to appear in about a week's time after sowing, and soon after will raise their heads upright; therefore, when the stems are advanced above ground, you should gently draw a little earth up to them, observing to do it when the ground is dry, which will preserve them from being injured by sharp winds; but you should be careful not to draw any of the earth over their seed-leaves, which would rot them, or at least greatly retard their growth. After this, they will require no farther care but to stick them when the plants begin to run, and to keep them clear from weeds until they produce fruit, when they should be carefully gathered two or three times a week; for if they are permitted to remain upon the plants a little too long, the Beans will be too large for eating, and the plants would be greatly weakened thereby.

The large sorts of Kidney-bean must be planted at a greater distance, row from row; for as these grow very tall, so if the rows are not at a greater distance, the sun and air will be excluded from the middle rows, therefore these should not be less than four feet distance row from row; and when the plants are about four inches high, the stakes should be thrust into the ground

ground by the side of the plants, to which they will fasten themselves, and climb to the height of eight or ten feet, and bear plenty of fruit from the ground upward. The Dutch and French preserve great quantities of the large Dutch Beans for winter use, which they stew, and make good with gravy and other sauces.

There are some persons who raise these in hot-beds, in order to have them early. The only care to be taken in the management of these plants when thus raised, is to allow them room, and give them as much air as can be conveniently when the weather is mild, as also to let them have but a moderate heat; for if the bed is over hot, they will either burn or be drawn up so weak as seldom to come to good.

The manner of making the hot-bed being the same as for Cucumbers, &c. need not be repeated in this place; but only observe, when the dung is equally levelled, to lay the earth about four or five inches thick, and let the great steam of the bed pass off before you sow the seeds. The time for doing this must be proportioned to the season when you would have the Beans for the table, but the surest time for a crop is about a week in February.

The manner of saving the seeds of these plants, is to let a few rows of them remain ungathered in the height of the season; for if you gather from the plants for some time, and afterwards leave the remaining for seed, their pods will not be near so long and handsome, nor will the seed be so good. In autumn, when you find they are ripe, you should in a dry season pull up the plants, and spread them abroad to dry; after which you may thresh out the seed, and preserve it in a dry place for use.

PELLANDRIUM, Water Hemlock.

There are two species of this genus at present known; one of which grows naturally in standing waters and deep ditches in several parts of England, the other is found on the Alps; but as neither are cultivated, so I shall not trouble the reader with any farther account of them.

PHILADELPHUS. Lin. Gen. Plant. 540. Syringa. Tourn. Inst. R. H. 617. tab. 389. Syringa, Pipe-tree, or Mock-orange.

The CHARACTERS are,

It hath a permanent empalement of one leaf, cut into five acute parts sitting upon the germen. It hath four or five roundish plain petals which spread open, and twenty or more awl-shaped stamina inserted to the empalement, terminated by erect summits with four furrows. The germen is situated under the flower, supporting a slender style divided in four parts, each being crowned by a single stigma. The germen afterward becomes an oval acute-pointed capsule having four cells, which are filled with small oblong seeds.

This genus of plants is ranged in the first section of Linnæus's twelfth class, which includes those plants whose flowers have about twenty stamina, which are fixed either to the petals or empalement of the flower.

The SPECIES are,

1. PHILADELPHUS (*Coronarius*) foliis subdentatis. Lin. Sp. 671. *Philadelphus with indented leaves.* Syringa alba, sive Philadelphus Athenæzi. C. B. P. *White Syringa, or Mock-orange.*
2. PHILADELPHUS (*Nanus*) foliis ovatis subdentatis, flore solitario pleno. Syringa or Mock-orange, with oval leaves which are somewhat indented, and double flowers standing singly on the sides of the branches. Syringa nana nunquam florens. Cat. Hort. Angl. *Dwarf Syringa which seldom flowers.*
3. PHILADELPHUS (*Inodorus*) foliis integerrimis. Lin. Sp. Plant. 672. *Philadelphus with entire leaves.* Philadelphus flore albo majore inodoro. Catesb. Carol. 1. p. 84. tab. 84. *Syringa with a larger white flower having no scent.*

The first sort has been long cultivated in the English gardens as a flowering shrub, but the place where it naturally grows is uncertain. This sends up a great number of slender stalks from the root, having a gray bark, sending out several short branches from their

side, garnished with oval spear-shaped leaves; those upon the young shoots are three inches and a half long, and two broad in the middle, lessening toward both ends, and terminating in acute points, having several indentures on their edges, their surface rough, and of a deep green on their upper side, but pale on their under, and have the taste of fresh Cucumbers; these stand opposite upon very short foot-stalks. The flowers come out from the side; and at the end of the branches, in loose bunches, each standing on a short distinct foot-stalk; they have four oval petals which spread open, with a great number of stamina within, surrounding the style. The flowers are white, and have a strong scent, which at some distance resembles that of Orange-flowers, but when near is too powerful for most persons. These appear the latter end of May, and continue great part of June, but are seldom succeeded by seeds which ripen in this country. This shrub rises seven or eight feet high.

There is a variety of this with variegated leaves, which some people preserve in their gardens; but as the stripes generally disappear when the plants are in health, so it makes little appearance.

The second sort is of humble growth, seldom rising above three feet high; the leaves are shorter than those of the former, and approach near to an oval form; they are but little indented on their edges. The flowers come out singly from the side of the branches, and have a double or treble row of petals, of the same size and form as the other, and the flowers have the same scent; but this sort flowers very rarely, so is not much esteemed.

Both these are extreme hardy, and will thrive in almost any soil or situation, but will grow taller in light good ground than in that which is stiff. They are usually propagated by suckers, which are sent out from their roots in great plenty; these should be taken from the old plants in autumn, and planted in a nursery to grow one or two years till they have obtained strength, and then they should be transplanted to the place where they are designed to remain. They are commonly disposed in wilderness work, among other shrubs of the same growth, where they add to the variety.

The third sort grows naturally in Carolina, and is as yet very rare in Europe. This rises with a shrubby stalk about sixteen feet high, sending out slender branches from the sides opposite, garnished with smooth leaves shaped like those of the Pear-tree, which are entire, standing also opposite on pretty long foot-stalks. The flowers are produced at the end of the branches; they are large, each having four oval petals which spread open, and have large empalements, composed of four acute-pointed leaves. The petals are white, and within these stand a great number of short stamina, terminated by yellow summits. The flowers are succeeded by oval capsules, filled with small seeds.

This shrub is very rare in England, for it rarely will rise from seeds; I have sown the seeds, which were sent me by the late Dr. Dale from Carolina, two or three times without any success, and others have done the same, which occasions its present scarcity in England; but when the plants are procured from abroad, they may be propagated by laying down their branches. I had one of the shrubs which was sent me by the gentleman before-mentioned, which had thriven in the Chelsea Garden near two years; and some of the branches which were laid down had put out roots, but they were all destroyed by cold in the winter, 1740.

PHILLYREA. Tourn. Inst. R. H. 596. tab. 367. Lin. Gen. Plant. 16. Phillyrea, or Mock Privet; in French, *Filaria*.

The CHARACTERS are,

The flower has a small permanent empalement of one leaf, cut into five segments at the brim. It has one petal, with a very short tube cut into five parts, which turn backward, and two short stamina standing opposite, terminated by single erect summits. It has a roundish germen, supporting

supporting a slender style the length of the stamina, crowned by a thick stigma. The germen afterward turns to a globular berry with one cell, inclosing one large roundish seed.

This genus of plants is ranged in the first section of Linnaeus's second class, which contains those plants whose flowers have two stamina and one style.

The SPECIES are,

1. PHILLYREA (*Latifolia*) foliis ovato-lanceolatis integerrimis. *Phillyrea* with oval, spear-shaped, entire leaves. *Phillyrea latifolia* laevis. C. B. P. 476. Broad-leaved smooth *Phillyrea*, commonly called the true *Phillyrea*.
2. PHILLYREA (*Media*) foliis ovatis subintegerrimis. Lin. Sp. 10. *Phillyrea* with oval leaves, which are almost entire. *Phillyrea folio leviter serrato*. C. B. P. *Phillyrea* with a leaf lightly sawed, called broad-leaved *Phillyrea*.
3. PHILLYREA (*Spinosa*) foliis cordato-ovatis serratis. Hort. Cliff. 4. *Phillyrea* with oval heart-shaped leaves, which are sawed. *Phillyrea latifolia spinosa*. C. B. P. 476. Broad-leaved prickly *Phillyrea*.
4. PHILLYREA (*Ligustrifolia*) foliis lanceolatis integerrimis. Hort. Cliff. 4. *Phillyrea* with spear-shaped entire leaves. *Phillyrea folio ligustri*. C. B. P. 476. Privet-leaved *Phillyrea*.
5. PHILLYREA (*Oleaeifolia*) foliis lanceolato-ovatis integerrimis, floribus confertis axillaribus. *Phillyrea* with spear-shaped, oval, entire leaves, and flowers growing in clusters from the sides of the branches. *Phillyrea olæ Ephesiaceae folio*. Pluk. Alm. 295. Phyt. tab. 310. fig. 3. Olive-leaved *Phillyrea*.
6. PHILLYREA (*Angustifolia*) foliis linearilanceolatis integerrimis, floribus confertis axillaribus. *Phillyrea* with narrow, spear-shaped, entire leaves, and flowers growing in clusters from the sides of the branches. *Phillyrea angustifolia prima*. C. B. P. 476. First narrow-leaved *Phillyrea*.
7. PHILLYREA (*Rosmarinisolia*) foliis linearibus integerrimis. *Phillyrea* with very narrow entire leaves. *Phillyrea angustifolia secunda*. C. B. P. 476. Second narrow-leaved *Phillyrea*, commonly called Rosemary-leaved *Phillyrea*.

The first sort here mentioned is the most common in the English gardens, where it is known by the title of true *Phillyrea*; so called, to distinguish it from the *Alaternus*, which is called simply *Phillyrea* by the gardeners. This rises with a strong upright stem to the height of eighteen or twenty feet, dividing into several branches, covered with a smooth grayish bark, and garnished with oval spear-shaped leaves placed opposite, which are entire, firm, and of a light green, about an inch and a half long, and an inch broad, standing upon short foot-stalks. The flowers come out from the wings of the stalk on each side; they are of an herbaceous white colour, and grow in small clusters. These appear in March, but as they are small make no great appearance; they are succeeded by globular berries with one cell, inclosing a single seed of the same form.

The second sort rises to an equal height with the first, but the branches are more diffused, and have a darker bark; the leaves are oval, and of a darker green; they are more than two inches long, and almost an inch and a half broad, a little sawed on their edges, placed opposite, and have short foot-stalks. The flowers come out from the wings of the branches, growing in long bunches; they are of an herbaceous white colour, appear about the same time as the former, and are succeeded by berries of the same form. The third sort rises with an upright stem as high as the two former, sending out several strong branches which grow erect, covered with a gray bark, and garnished with oval heart-shaped leaves, about an inch and a half long, and one inch broad; they are firm, of a lucid green, and sawed on their edges, each serrature ending in a spine. The flowers and seeds of this are like those of the two former sorts.

The fourth sort is of humbler growth than either of the former, seldom rising more than eight or ten feet high; the branches are weaker, and spread wider,

and are covered with a light brown bark, and garnished with stiff spear-shaped leaves almost two inches long, and half an inch broad in the middle, drawing to a point at both ends; they are of a light green, and sit close to the branches opposite. The flowers are produced in small clusters at the wings of the branches; they are small, and whiter than those of the former, appearing about the same time, and are succeeded by small berries which ripen in autumn.

The fifth sort rises about the same height as the fourth; the branches are stronger, and spread out wider; the bark is of a lighter colour; the leaves are stiff, smooth, and entire, standing opposite on very short foot-stalks; they are of a lucid green, and terminate in a point. The flowers come out in clusters upon pretty long foot-stalks, at the wings of the young branches; they are small, white, and appear at the same time with the other sorts, and have round berries succeeding them, which ripen in autumn.

The sixth sort rises with a woody stalk ten or twelve feet high, sending out branches opposite, which are covered with a brown bark spotted with white, garnished with smooth, stiff, narrow, spear-shaped leaves, which are entire, sitting close to the branches; they are about an inch and a half long, and half an inch broad in the middle, drawing to a point at both ends, of a light green, and point upward. The flowers come out in large clusters at each joint of the branches, to which they sit close like the whorled flowers, almost surrounding the stalk; these are small, white, and appear at the same time as the former, and are succeeded by small berries, which ripen in autumn.

The seventh sort is of humbler growth than either of the former, seldom rising more than four or five feet high, sending out slender branches opposite, which are sparsely disposed; the leaves are of a dark green, stiff, and entire; they are about an inch long, and not more than one eighth of an inch broad, sitting close to the branches. The flowers are small, white, and grow in clusters from the side of the branches. The berries of this sort are very small, and rarely ripen in England.

These plants all grow naturally in the south of France, Spain, and Italy, but are hardy enough to thrive in the open air in England, and are never injured except the winters are very severe, which sometimes causes their leaves to fall, and kills a few of the weaker branches, but these are repaired by new shoots the following summer; so that there are but few of the evergreen-trees which are hardier than these, or that deserve more to be cultivated for pleasure.

Formerly these were either planted against walls, to which they were trained to cover them; or if they were placed as standards, their branches were sheared either into balls or pyramids, like most of the evergreen-trees; so that when the former old taste of laying out gardens was exploded, the evergreens were generally banished; and for some years there were but few sorts cultivated, whereby several valuable kinds of evergreen-trees were almost entirely lost in England, and have been with difficulty retrieved since; for in the manner which the evergreen-trees and shrubs are now disposed in gardens, they have a very fine effect, especially during the winter season, when the other trees are destitute of leaves.

There are some other sorts mentioned to grow naturally in Spain and Italy, but those here mentioned are all that I have seen growing in the English gardens; and several of these have been supposed only accidental varieties, which have been produced from seeds; but I am more inclined to believe they are specifically different, for I have raised most of these from seeds which were sent me from Italy, where the sorts were carefully gathered distinct, and have never yet found them vary from the kinds the seeds were taken; so that I imagine those seeds from which two or three kinds have been raised, were gathered from different plants without care.

The three first sorts are very proper to intermix with other evergreen-trees of the same growth, to form

clumps in parks, or to plant round the borders of woods, which are filled with deciduous trees, where in the summer time, the dark shade of these evergreens will make a fine contrast with the brighter green leaves of the deciduous trees; and in winter, when the latter are destitute of leaves, they will have a fine effect, and will be a fine harbour for birds. These may be trained up to stems, so as to be out of the reach of cattle, therefore may be planted in open places, where, if they are fenced against cattle till they are grown up, they may be afterwards exposed.

The other sorts, which are of humbler growth, must be confined to gardens or other inclosures, where they may be secured from cattle, hares, rabbits, &c. otherwise they will be soon destroyed.

These plants are propagated either from seeds or layers, but the latter being the most expeditious method in England, is chiefly preferred. The best time to lay them down is in autumn, when you should dig the ground round the stems of the plants intended to be layed, making it very loose; then making choice of a smooth part of the shoot, you should make a slit upward (in the manner as is practised in laying of Carnations) and then bend the branch gently down to the ground, making a hollow place with your hand to receive it; and having placed the part which was slit into the ground, so as that the slit may be open, you should fasten it down with a forked stick that it may remain steady, covering that part of the branch with earth about three inches thick, observing to keep the upper part erect. You must keep them clear from weeds the spring and summer following, which, if suffered to grow up amongst them, will prevent their taking root.

The autumn following most of these plants will be rooted, at which time they may be taken off, and carefully planted in a nursery, where they may be trained up three or four years in the manner you intend them to grow; during which time you should dig the ground between the rows, and cut about the roots of the plants every year, which will cause them to strike out strong fibres, so as to support a good ball of earth when they are removed; you should also support their stems with stakes, in order to make them straight, otherwise they are very apt to grow crooked and unsightly.

When the plants have been thus managed three or four years, you may transplant them into the places where they are designed to remain. The best time for this work is the latter end of September, or the beginning of October; but in removing them, you should dig round their roots, and cut off all down-right or strong roots, which have shot out to a great distance, that you may the better preserve a ball of earth to each plant, otherwise they are subject to miscarry; and when you have placed them in their new quarters, you should lay some mulch upon the surface of the ground to prevent its drying. You should also support the plants with stakes, until they have taken full hold of the earth, to prevent their being turned out of the ground, or displaced by the winds, which will destroy the fibres that were newly put out, and greatly injure the plants. These trees delight in a middling soil, which is neither too wet and stiff, nor too dry, though the latter is to be preferred to the former, provided it be fresh.

Those sorts with small leaves are commonly two years before they take root when laid, therefore they should not be disturbed, for the raising them out of the ground greatly retards their rooting.

If these plants are propagated by seeds, they should be sown in the autumn soon after they are ripe, for when they are kept out of the ground till spring, they do not grow the first year. The seeds will do best if they are sown in pots or boxes filled with light loamy earth, and placed under a garden frame where they may be screened from hard frost, but always exposed to the open air in mild weather. If the seeds are sown early in the autumn, the plants will appear

in the spring; but if they should not come up, the pots should be plunged into the ground in an east border, where they may only have the morning sun, in which situation they should remain the following summer; during which time they may be constantly kept clean from weeds, and in the autumn removed again under a frame for shelter in winter, and the spring following the plants will certainly come up, if the seeds were good. Toward the middle of April, the pots should be again plunged into the ground on an east border, to prevent the air from drying the earth through the pots, which is generally the case when the pots stand upon the ground; so that they must then be frequently watered, which should not be practised to these plants where it can be avoided. The Michaelmas following the plants should be carefully taken out of the pots, and planted in a nursery-bed, covering the surface with old tan to keep out the frost; and if the winter prove severe, they should be covered with mats, afterward they may be treated as the layers.

PHILLYREA OF THE CAPE. See MAUROCENA.

PHLOMIS. Tourn. Inst. R. H. 177. tab. 82. Lin. Gen. Plant. 642. [*φλομῖς*, so called of *φλέγω*, to burn, because in old time the peasants used to burn these plants to enlighten their chambers.] The Sage-tree, or Jerusalem Sage.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, having an oblong tube with five angles. It hath one petal, and is of the lip kind; the tube is oblong; the upper lip is oval, forked, and inflexed; the under is cut into three segments, the middle one being large and obtuse. It hath four stamina hid under the upper lip, two being longer than the other, terminated by oblong summits, and a germen divided into four parts, supporting a style the length of the stamina, crowned by an acute bifid stigma. The germen afterward become four oblong cornered seeds sitting in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, which contains the plants whose flowers have two short and two longer stamina, and the seeds sit naked in the empalement.

The SPECIES are,

1. **PHLOMIS** (*Fruticosa*) foliis subrotundis tomentosis crenatis, involucris lanceolatis caule fruticoso. Lin. Sp. 818. *Phlomis with roundish, woolly, crenated leaves, and a shrubby stalk.* *Phlomis fruticosa*, *salviæ folio latiore & rotundiore.* Tourn. Inst. 177. *Shrubby Jerusalem Sage, with a broader and rounder Sage leaf.*
2. **PHLOMIS** (*Angustifolia*) foliis ovato-lanceolatis tomentosis integerrimis, caule fruticoso. *Phlomis with oval, spear-shaped, woolly leaves which are entire, and a shrubby stalk.* *Phlomis fruticosa*, *salviæ folio longiore & angustiore.* Tourn. Inst. 177. *Shrubby Jerusalem Sage, with a longer and narrower Sage leaf.*
3. **PHLOMIS** (*Latifolia*) foliis oblongo-ovatis petiolatis tomentosis, floribus capitatis, caule fruticoso. *Phlomis with oblong, oval, woolly leaves having foot-stalks, flowers growing in large heads, and a shrubby stalk.* *Phlomis latifolia*, *capitata, lutea, grandiflora.* Hort. Elth. 316. *Broad-leaved Jerusalem Sage, with large yellow flowers growing in heads.*
4. **PHLOMIS** (*Herba Venti*) involucris setaceis hispidis, foliis ovato-oblongis scabris, caule herbacea. Hort. Upsal. 171. *Phlomis with bristly prickly involucrems, oblong, oval, rough leaves, and an herbaceous stalk.* *Phlomis Narbonensis*, *hormini folio, flore purpurascente.* Tourn. Inst. R. H. 178. *Jerusalem Sage of Narbonne, with a Clary leaf and a purplish flower.*
5. **PHLOMIS** (*Tuberosa*) involucris hispidis subulatis, foliis cordatis scabris, caule herbacea. Hort. Upsal. 171. *Phlomis with awl-shaped prickly involucrems, rough heart-shaped leaves, and an herbaceous stalk.* *Phlomis urticæ folio glabro.* Amman. Ruth. 40. *Jerusalem Sage with a smooth Nettle leaf.*
6. **PHLOMIS** (*Lychnitis*) foliis lanceolatis tomentosis, floralibus ovatis, involucris setaceis lanatis. Lin. Sp. Plant. 585. *Phlomis with spear-shaped woolly leaves, those under the flowers oval, and bristly woolly involucrems.*

crums. *Phlomis lychnitis*. Clus. Hist. 27. *Narrow-leaved Jerusalem Sage*.

7. *PHLOMIS (Purpurea)* foliis ovato-lanceolatis crenatis, subtus tomentosis, involucris setaceis. *Phlomis with oval spear-shaped leaves, which are woolly on their under side, and have a bristly involucre.* *Phlomis fruticosa* Lusitanica, flore purpurascens, foliis acutioribus. Tourn. Inst. 178. *Shrubby Portugal Phlomis with a purplish flower, and acute-pointed leaves.*
 8. *PHLOMIS (Samia)* foliis cordatis acutis subtus tomentosis, involucris strictis tripartitis. *Phlomis with acute-pointed heart-shaped leaves, which are woolly on their under side, and the covers of the flowers divided into three parts.* *Phlomis Samia herbacea, folio lunariæ.* Tourn. Cor. 10. *Herbaceous Samian Jerusalem Sage, with a Moon-wort-leaf.*
 9. *PHLOMIS (Orientalis)* foliis cordatis rugosis subtus tomentosis, involucris lanatis, caule herbaceo. *Phlomis with rough heart-shaped leaves, which are woolly on their under side, woolly covers to the flowers, and an herbaceous stalk.* *Phlomis orientalis lutea herbacea latifolia, verticillata.* Phil. Trans. vol. 34. *Yellow, herbaceous, eastern Jerusalem Sage, having a broad leaf, and flowers growing in whorls.*
 10. *PHLOMIS (Flavescentia)* foliis lanceolatis crenatis subtus tomentosis, involucris lanatis, caule fruticoso. *Phlomis with spear-shaped crenated leaves, which are woolly on their under side, woolly covers to the flowers, and a shrubby stalk.* *Phlomis angustifolia lutea, cymis flavescentibus.* Sherard. Phil. Trans. N° 376. *Yellow narrow-leaved Jerusalem Sage, with yellowish tops.*
 11. *PHLOMIS (Nisolia)* foliis radicalibus cordatis utrinque tomentosis villosis. Lin. Sp. Plant. 585. *Phlomis whose lower leaves are heart-shaped, woolly, and hairy on every side.* *Phlomis orientalis, foliis auriculatis incanis, flore luteo.* Nissol. *Eastern Jerusalem Sage, with hoary eared leaves, and a yellow flower.*
 12. *PHLOMIS (Ferruginea)* involucris lanceolatis, foliis cordatis subtus tomentosis, caule suffruticoso. *Phlomis with spear-shaped involucres, heart-shaped leaves which are woolly, and a shrubby stalk.* *Phlomis Hispanica, fruticosa, candidissima, flore ferrugineo.* Tourn. Inst. 178. *Whitest, shrubby, Spanish Jerusalem Sage, with an iron-coloured flower.*
 13. *PHLOMIS (Rotundifolia)* involucris subulatis, foliis cordato-ovatis subtus tomentosis, caule fruticoso. *Phlomis with awl-shaped involucres, oval heart-shaped leaves which are woolly on their under side, and a shrubby stalk.* *Phlomis fruticosa, flore purpureo, foliis rotundioribus.* Tourn. Inst. 178. *Shrubby Jerusalem Sage with a purple flower, and rounder leaves.*
 14. *PHLOMIS (Laciniata)* foliis alternatim pinnatis, foliolis laciniatis, calycibus lanatis. Lin. Sp. Plant. 585. *Phlomis with leaves alternately winged, whose lobes are cut, and having woolly empalements to the flowers.* *Phlomis orientalis foliis laciniatis.* Tourn. Cor. 10. *Eastern Jerusalem Sage with jagged-leaves.*
- The first sort grows naturally in Spain and Sicily; this hath a pretty thick shrubby stalk, covered with a loose bark rising five or six feet high, dividing into many irregular branches, which are four-cornered and woolly when young, but afterward become ligneous. Their joints are pretty far asunder; at each of these are placed two roundish leaves opposite, on short foot-stalks; they are woolly on their under side. The flowers come out in thick whorls round the stalks; they are yellow, and have two lips; the upper lip is forked, bending over the under, which is divided into three parts; the middle is broad, and stretched out beyond the two small side segments. The flowers appear in June, July, and August, but are very rarely succeeded by seeds here.
- The second sort hath a shrubby stalk like the first, but does not rise so high. The branches are weaker; the leaves are spear-shaped and oval, being longer, narrower, and rounder at both points than the former; the whorls of flowers are smaller, but the flowers are of the same shape and colour. Its flowers about the same time as the former.
- These two sorts have been long propagated in the Eng-

lish gardens by the title of Sage-tree, or Jerusalem Sage. The plants were formerly kept in pots, and housed in winter with other exotic plants; but of late years they have been planted in the open air, where they are seldom injured by cold, unless in very severe winters; so they are intermixed with other shrubs of the same growth in quarters of wilderness-work, where they add to the variety; for as they retain their hoary woolly leaves all the year, they make a good appearance in winter; and their yellow flowers, which continue great part of the summer, being intermixed with their hoary leaves, have a good effect.

These plants should have a dry soil and a warm sheltered situation, otherwise they will not live in the open air. They may be planted among Cistuses of all the different kinds, the shrubby Moon-trefoil, evergreen Cytisus, Wormwood-tree, and some other exotic shrubs of the same countries, which require a warm situation and a dry soil, being too tender for open plantations which are exposed to strong cold winds; and as they are not of long duration, they are better when separated from trees and shrubs which continue many years; for these rarely live above twelve or fourteen years in dry ground, and not more than half so long in cold moist land, or where they are not well sheltered.

They are propagated by cuttings, which if planted in a bed of light earth in April, just before the plants begin to shoot, and covered with mats to screen them from the sun every day, as also to observe when the ground is dry to give them water gently, they will get good roots in about two months or ten weeks, when they may be carefully taken up, and transplanted into a nursery, where they may remain one year, and then be transplanted to the places where they are designed to stand, for these plants will not bear transplanting at a greater age.

The third sort hath a shrubby stalk like the former, but much lower, seldom rising more than three feet and a half high, sending out branches on every side, which are garnished with broader hoary leaves than either of the former; these are of an oblong oval form, and have pretty long foot-stalks; they are whiter than those of the former. The flowers grow in large whorls or heads, which generally terminate the branches; they are larger than those of the other sorts, and the upper lip is very hairy. These appear about the same time as those of the other sorts. The plants are equally hardy, and may be propagated by cuttings in the same way as is before directed for them.

The fourth sort grows naturally in the south of France and in Italy; this hath a perennial root, and an annual stalk which rises about two feet high, and decays in the autumn. When the roots are large, they send up a great number of square stalks, which are covered with a hairy down, and garnished with oblong, oval, rough leaves placed opposite, sitting close to the stalks. The flowers grow in whorls round the stalks, having stinging bristly covers; they are of a bright purple colour, so make a pretty appearance. They appear at the same time with the former, but are rarely succeeded by seeds in England.

This may be propagated by parting the roots; the best time for doing this is in the autumn, when the stalks begin to decay, that they may get root before the frost comes on; but they should not be parted oftener than every third or fourth year, if they are expected to have many flowers. This sort is hardy, so may be planted in exposed places, but it should not be planted in moist ground.

The fifth sort grows naturally in Tartary; this hath a perennial root. The stalks are purple, have four corners, and rise five or six feet high, garnished with heart-shaped leaves placed opposite; they are six inches long, and three broad at their base, but terminate in acute points, and are deeply crenated on their edges. The flowers grow in whorls round the stalks; their covers are awl-shaped, and are set with stinging hairs; they are of a pale purple colour and hairy. These appear

P H L

pear in June and July, and are succeeded by seeds which ripen in September; soon after which the stalks decay, but the roots will abide many years. It is propagated by seeds, which should be sown upon an east border in the spring, and when the plants come up, they must be kept clean from weeds the following summer, and in the autumn they should be transplanted where they are to remain; the following summer they will produce flowers and seeds. This sort is very hardy, so will thrive in almost any soil or situation.

The sixth sort grows naturally in the south of France, in Spain and Italy; the root is perennial, and the stalk annual. This sends out long, narrow, woolly leaves from the roots in tufts, which are enveloped at their base by a common covering; they are soft to the touch, and lie upon the ground. The stalks are slender, and near two feet long; their joints are far asunder; at each of these stand two oval leaves opposite, which embrace the stalk with their base. The whorls of flowers are also encompassed by these leaves, and within them is situated a radiated bristly involucre, which covers the flowers, which are yellow, and shaped like those of the other sorts. These appear in July, but are rarely succeeded by seeds in England. The stalks decay in the autumn, but the lower leaves remain all the year. It may be propagated by slips in the spring, and the plants require a dry soil and a warm situation.

The seventh sort grows naturally in Portugal and Spain. This hath a shrubby stalk which rises four or five feet high, sending out slender branches, which have four angles covered with a white bark, garnished with oval spear-shaped leaves about four inches long, and an inch and a half broad at their base; they are crenated on their edges, and woolly on their under side, standing upon very short foot-stalks. The flowers come out in whorls at each joint; they have bristly involucres, and are of a deep purple colour. This flowers in June and July, but does not ripen seeds in England. It may be propagated by cuttings in the same way as the three first sorts, and the plants require the same treatment.

The eighth sort was discovered by the late Dr. Tournefort in the Levant, where it grows naturally; this hath a perennial root and an annual stalk. The leaves of this are heart-shaped; those at the root are three inches long, and an inch and a half broad at their base, ending in acute points; they are downy on their under side, and have five strong veins. The stalks rise a foot and a half high, and are garnished at each joint with two leaves placed opposite, of the same form as the lower, but smaller. The flowers grow in whorls round the stalks; they are of a worn-out purple colour; their involucres are cut into segments, and are closely shut. This never produces seeds here, and the roots increase very slowly, so that now it is very rare in Europe; for before the severe winter in 1740, these plants had lived abroad in warm borders upward of twenty years, so that there were none of the plants kept in pots, and that year they were almost all destroyed in England.

The seeds of the ninth sort were sent from Smyrna by the late Consul Sherard to the Chelsea Garden, where the plants were raised; this hath a perennial root and an annual stalk. The lower leaves are near three inches long, and an inch and a half broad, standing upon long woolly foot-stalks; they are rough on their upper side, but woolly on their under, and are heart-shaped and entire. The stalks, which rise a foot high, are very downy; the flowers grow in whorls round the stalks; they have very long tubulous empalements covered with down; they are very large, and of a bright yellow, so make a good appearance. It flowers the latter end of June, and in July, but never ripens seeds in England. This sort hath survived many winters in the open air in the Chelsea Garden, but in the year 1740 they were all destroyed.

The seeds of the tenth sort were also sent from Smyrna by the same gentleman, and several of the plants were

P H L

raised in the Chelsea Garden. This hath shrubby stalks which rise about three feet high, and are covered with a yellowish down, sending out many slender irregular branches, garnished with narrow spear-shaped leaves, which are covered with a yellowish down on their under side. The flowers are produced in heads at the end of the branches; their involucres are very downy; the flowers are smaller than those of either of the first sorts, and are of a dirty yellow colour. This approaches near to the second sort, but the leaves are much smaller, the branches are slenderer, and are covered with a yellow down, especially toward the end of the branches. The whorls of flowers are not near so large, and are generally produced at the end of the branches.

This sort may be propagated by cuttings in the same way as the three first sorts, and the plants may be treated in the like manner, with this difference only, of planting them in a warmer situation, for it will not bear so much cold, though in a warm border the plants have lived several years abroad in the Chelsea Garden.

The eleventh sort grows naturally in the Archipelago, and also in Spain, from both which countries I have received the seeds. This plant hath an annual stalk, but the root is perennial, as are also the lower leaves, which do not arise from the root immediately, but stand in clusters upon short, trailing, woolly branches; they have very long downy foot-stalks, and are placed without order; they are heart-shaped, and downy on both sides, about four inches long, and two broad toward their base. The stalks are slender, and rise a foot high, garnished with oval spear-shaped leaves, which gradually decrease in size to the top, where they are not half an inch long. These stalks generally send out two side branches opposite, near the bottom, and from this division to the top are garnished with thin whorls of yellow flowers, which are not closely joined together as in the other species, but each flower stands separate. Their empalements are oval, very downy, and closely shut up. The flowers appear in June and July, but there are seldom any seeds produced in England. This sort may be propagated by slips in the same manner as the sixth sort, and the plants should be treated in the like way.

The twelfth sort grows naturally in Spain and Portugal; this hath an almost shrubby stalk, which is a little ligneous, and rises about two feet and a half high, covered with a thick white down. There are many of the stalks which arise from the same root, garnished with heart-shaped leaves about two inches long, and one broad toward their base; and from the lower part of the stalks, at each joint, there are two short shoots come out opposite, which have four or six small leaves of the same shape with the others, and are covered with a very white down. The flowers are produced in small whorls toward the upper part of the stalk; they have downy spear-shaped involucres; the flowers are short, and of an iron colour. They appear in June and July, but the plants produce no seeds in England.

This sort multiplies by its spreading roots, so that they may be divided every other year; the best time for doing this is about the middle of September, that the offsets may get root before the frost comes on; but there should be some mulch laid about their roots to prevent the frost from penetrating the ground. It may be also propagated by cuttings in the same way as the three first sorts, during the spring and summer months. The plants require the same treatment as the tenth sort, for they are not so hardy as the three first sorts; therefore, if there is some tan-bark, or other mulch laid upon the surface of the ground about their roots every winter, it will be a means of preserving the roots; so that if a severe winter should kill the stalks, the roots will put out new ones the spring following.

The thirteenth sort grows naturally in Spain and Portugal. This rises with several shrubby stalks from three to four feet high, which divide into several four-cornered

cornered branches covered with a woolly down, and garnished with leaves which on the lower part of the stalks are heart-shaped, but upward they are of an oval spear-shape, and woolly on their under side; they stand opposite upon short foot-stalks. The flowers come out in whorls round the stalks; they have awl-shaped involucrum ending in acute points, and covered with down; the flowers are of a bright purple colour, and appear in June, but are not succeeded by seeds in this country. This sort is propagated by cuttings in the same way as the three first sorts, and the plants should be treated in the like manner as hath been before directed for the tenth sort.

The fourteenth sort was discovered by Dr. Tournefort in the Levant, from whence he sent the seeds to the Royal Garden at Paris, where they succeeded. This sort hath a perennial root and an annual stalk which decays in the autumn, but the lower leaves continue all the year; these are alternately winged, and the small lobes are cut on their edges. The stalks rise a foot and a half high, garnished with leaves of the same shape with the lower, but are smaller. The flowers come out in whorls round the stalks, like those of the other sorts, whose empalements are downy; they are of a worn-out purple colour, and appear in June, but the seeds do not ripen here.

It is propagated by offsets from the root in the same way as the eighth sort, but these are sent out sparingly also, and the plants require the same treatment as those of the eighth sort. It is at present very rare in England, for the severe frost in the year 1740 destroyed all the plants in England, many of which had survived all the winters for twenty years before in the open air.

All the species of this genus are ornamental plants when properly disposed in gardens, so deserve a place there, for there is generally a succession of flowers on them for two or three months, and their hoary downy leaves, when intermixed with plants whose leaves are green, make a pretty contrast.

The leaves of the two first sorts have been greatly recommended by some persons to be used as tea for sore throats.

PHLOX. Lin. Gen. Plant. 197. *Lychnidea*. Dill. Hort. Elth. 166. *Lychnidea*, or *Bastard Lychnis*.

The CHARACTERS are,

The flower has a cylindrical empalement of one leaf, which is permanent, and hath five acute indentures at the top. It has one funnel-shaped petal, with a cylindrical tube narrow at the base, where it is incurved, and plain at the top, and is cut into five equal roundish segments which spread open. It hath five short stamina situated within the tube, two of which are longer than the tube, terminated by summits in the chaps of the flower. It hath a conical germen, supporting a slender style the length of the stamina, crowned by an acute trifid stigma. The germen afterward turns to an oval capsule with three cells fitting in the empalement, each cell containing a single seed.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style; but were it not for the number of stamina, it would be better placed among the ringent plants in the second section of his fourteenth class, the structure of the flower being the same with those there ranged.

The SPECIES are,

1. **PHLOX** (*Glaberrima*) foliis lineari-lanceolatis glabris acuminatis, caule erecto ramoso, corymbo terminali. Lin. Sp. 217. *Pblox with smooth, narrow, spear-shaped leaves ending in acute points, and upright branching stalks terminated by flowers, which grow in a corymbus.* *Lychnidea Virginiana*, holostei ampliore folio, floribus umbellatis purpureis. Rand. Phil. Trans. vol. 34. *Virginia Bastard Lychnis with a larger Stitch-wort leaf, and purple flowers growing in umbels.*
2. **PHLOX** (*Carolina*) foliis lanceolatis lævibus, caule scabro corymbus subfastigiatis. Lin. Sp. 216. *Pblox with smooth spear-shaped leaves, and upright stalks terminated by flowers growing in a corymbus.* *Lychnidea Caroliniana*, floribus quasi umbellatim dispositis, fo-

liis lucidis crassis acutis. Martyn. Dec. 1. *Bastard Lychnis of Carolina, with flowers disposed as it were in an umbel, and thick, shining, acute leaves.*

3. **PHLOX** (*Maculata*) foliis lanceolatis lævibus, racemoso opposito corymbo. Lin. Sp. Plant. 216. *Pblox with spear-shaped leaves which are smooth, and branching opposite flowers.* *Lychnoides Marylandica*, foliis binis oppositis basi & auriculis caulem utrinque amplexicaulibus. Raii Supp. 459. *Maryland Bastard Lychnis with leaves growing opposite, whose base embraces the stalks on both sides.*
4. **PHLOX** (*Divaricata*) foliis lato-lanceolatis, superioribus alternis, caule bifido pedunculis geminis. Lin. Sp. Plant. 217. *Pblox with broad spear-shaped leaves placed alternately at the top, and a branching stalk.* *Lychnidea Virginiana*, allines aquaticæ foliis, floribus in ramulis divaricatis. Pluk. Mant. 121. *Bastard Lychnis of Virginia with Water Chickweed leaves, and flower-branches diverging from each other.*
5. **PHLOX** (*Paniculatis*) foliis lanceolatis margine scabris, corymbis paniculatis. Lin. Sp. Plant. 216. *Pblox with spear-shaped leaves having rough borders, and flowers disposed in a compound corymbus.* *Lychnidea Virginiana*, umbellata maxima, *Lyfimachia luteæ* foliis amplioribus, binis ex adverso positis. Pluk. Mant. 121. *Bastard Lychnis of Virginia with the largest umbel, and large yellow Loostripe leaves placed opposite by pairs.*
6. **PHLOX** (*Pilosa*) foliis lanceolatis villosis, caule erecto, corymbo terminali. Lin. Sp. Plant. 216. *Pblox with hairy spear-shaped leaves, and an upright stalk terminated by a corymbus of flowers.* *Lychnoides Marylandica*, calycibus lanuginosis, foliis angustis acutis. Raii Supp. 490. *Bastard Lychnis of Maryland, with woolly empalements to the flowers, and narrow acute-pointed leaves.*
7. **PHLOX** (*Ovata*) foliis ovatis, floribus solitariis. Lin. Sp. Plant. 152. *Pblox with oval leaves and solitary flowers.* *Lychnidea fistulosa Marylandica*, clinopodii vulgaris folio, flore amplo singulari. Pluk. Mant. 122. *Fistulous Bastard Lychnis of Maryland, with a Field Basil leaf, and large flowers growing singly.*

The first sort grows naturally in Virginia, and in some other parts of North America, but has been several years pretty common in the English gardens. This hath a perennial root, which sends up several stalks, in number proportionable to the size of the roots; these rise near a foot and a half high, and divide into three or four small branches toward the top, which are terminated by a corymbus of flowers. The leaves on the lower part of the stalks are placed opposite, and are about three inches long, and near half an inch broad at their base, ending in long acute points; they are smooth, and set close to the stalks; the leaves on the upper part of the stalks are placed alternate. The flowers grow on the top of the stalks in a sort of corymbus, or rather in form of an umbel, many of them arising from the same point, standing on short foot-stalks; their empalements are tubulous, and have ten angles or furrows, and are cut at the top into five acute segments; the tube of the flower is twice the length of the empalement, and is divided at the top into five roundish segments which spread open; these are of a light purple colour, and appear in June, but unless the season proves warm, they are not succeeded by seeds in England.

The second sort grows naturally in Carolina; this hath a perennial root, from which arise several rough stalks near two feet high, garnished with stiff shining leaves placed opposite, sitting close to the stalks; they are spear-shaped, entire, and their edges are reflexed; the upper part of the stalk has generally two slender side branches, and is terminated by a head of flowers, which grow in whorls round the stalks; but the whorls are so nearly placed, as to appear one corymbus at some distance. The empalement of the flower is short, and deeply cut into five acute segments; the tube of the flower is long, and at the top is cut into five roundish segments, which spread open. These flowers are of a deeper purple colour than those of the former, and are a fortnight later before they appear.

The third sort grows naturally in Maryland; this hath a perennial root, from which arise several upright stalks of a purplish colour, closely covered with white spots; these grow about three feet high, and are garnished with heart spear-shaped leaves which are smooth, about three inches long and one broad at their base, ending in acute points. Toward the upper part of the stalks are sent out small branches opposite, each being terminated by a small bunch of flowers; but the principal stalk is terminated by a long loose spike of flowers, composed of small bunches arising from the wings of the stalk at each joint, each cluster having one common foot-stalk near an inch long, but the simple foot-stalks of the flowers are short; the flowers are of a bright purple colour, and appear late in July; so that if the season is temperate, or the soil in which they grow moist, they will continue in beauty great part of August, but are rarely succeeded by seeds in England.

The fourth sort grows naturally in North America; this has a perennial root, from which arise several slender stalks, which are apt to incline to the ground if they are not supported; these divide into several small branches, which spread from each other; the lower part of the stalks are garnished with broad spear-shaped leaves placed alternate, sitting close to the stalks, and on the smaller branches they are narrower, and placed opposite. The flowers grow in loose bunches at the end of the branches; they have short empalements, which are cut into five, narrow, acute segments; the tube of the flower is long and slender, the segments at the top are broad and heart-shaped, inverted. They are of a light blue, and appear the latter end of May or the beginning of June, but are rarely succeeded by seeds in England.

The fifth sort grows naturally in North America; this hath a perennial root and an annual stalk, which is smooth, of a light green, and rises about two feet high, sending out a few side branches, garnished with spear-shaped leaves placed opposite, near three inches long and one broad at the middle, drawing to a point at each end, sitting close to the stalks; they are of a dark green, and their edges are a little rough. The flowers are disposed in a corymbus at the top of the stalks, composed of many smaller bunches of flowers, which have each a distinct foot-stalk, and support a great number of flowers, which stand upon short slender foot-stalks; the empalement of the flower is short, and cut almost to the bottom into five narrow acute segments; the tube of the flower is long and slender, and is cut at the top into five oval segments which spread open. The flowers are of a pale purple colour, and appear late in July, but these are often succeeded by seeds which ripen in autumn.

The sixth sort grows naturally in Virginia; this hath a perennial root, from which arise a few stalks about a foot high, garnished with narrow spear-shaped leaves, ending in acute points, sitting close to the stalks, and are a little hairy. The flowers are produced in a loose corymbus at the top of the stalk; their empalements are cut into acute segments almost to the bottom; the tube of the flower is slender and pretty long, and is cut at the top into five oval segments, which spread open. The flowers are of a light purple colour, and appear the latter end of June, but are seldom succeeded by seeds in England.

The seventh sort grows naturally in Maryland, and other parts of North America. This hath a perennial root, from which comes out two or three slender stalks about nine inches high, garnished with oval, rough, hairy leaves, an inch and a half long, and about three quarters of an inch broad in the middle; they are placed opposite upon very short foot stalks. The flowers come out singly at the top of the stalk; they have very slender tubes, but are cut into five roundish segments, which spread open. They are of a light purple colour, and appear in July, but are not succeeded by seeds in England.

These plants are hardy, so will thrive in the open air in England; they delight in a moist rich soil, not too

stiff, in which they will grow tall, and produce much larger bunches of flowers than in dry ground; for when the soil is poor and dry, they frequently die in summer, unless they are duly watered.

They are generally propagated by parting their roots, because they do not often produce seeds in England. The best time for this is in autumn, when their stalks begin to decay. These roots should not be divided into small heads, if they are expected to flower well the following summer; nor should they be parted oftener than every other year, because when they are often removed and parted, it will greatly weaken the roots, so that they will send out but few stalks, and those will be so weak as not to rise their usual height, and the bunches of flowers will be much smaller.

When the roots are transplanted and parted, it will be a good way to lay some old tan, or other mulch, upon the surface of the ground about their roots, to prevent the frost from penetrating the ground; for as they will have put out new fibres before winter, so the frost when it is severe often kills the fibres, whereby the plants suffer greatly, and are sometimes destroyed.

The first, second, and fifth sorts, propagate pretty fast by their spreading roots, but the others increase but slowly this way, therefore the best method to propagate them is by cuttings; and if the three first sorts are desired in plenty, they may be easily obtained by this method. The best time to plant the cuttings, is about the latter end of April or the beginning of May, when the shoots from the roots are about two inches high; these should be cut off close to the ground, and their tops should be shortened; then they must be planted on a border of light loamy earth, and shaded from the sun until they have taken root; or if they are planted pretty close together, and covered with bell or hand-glasses, shading them every day from the sun, they will put out roots in five or six weeks; but when they begin to shoot, the glasses should be gradually raised to admit the free air to them, otherwise they will draw up weak and soon spoil: as soon as they are well rooted, the glasses should be taken off, and the plants inured to the open air; then they should be soon after removed into a bed of good soil, planting them about six inches distance every way, observing to shade them from the sun, and water them duly till they have taken new root; after which, if they are kept clean from weeds, they will require no other care till autumn, when they should be transplanted into the borders of the flower-garden, where they are designed to remain.

If some of these plants are put into pots, and sheltered under a hot-bed frame in winter, they will flower strong the following summer; and these may be placed in court-yards, or other places near the habitation, when they are in beauty, and being mixed with other flowers will be very ornamental.

PHYLICA. Lin. Gen. Plant. 236. Alaternoides. Com. Hort. Amst. 1. p. 1. *Bastard Alaternus*.

The CHARACTERS are,

The flowers are collected in a disk, sitting in a common receptacle, each having a permanent empalement, composed of three narrow oblong leaves. They have one perforated petal, with an erect conical tube, cut into five parts at the brim, and an acute scale at each division, which join together within, and five small stamina inserted under the scales, terminated by single summits. The germen is situated at the bottom of the petal, supporting a single style, crowned by an obtuse stigma. The germen afterward becomes a roundish capsule with three lobes, having three cells, each inclosing a single roundish seed, gibbous on one side, and angular on the other.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. PHYLICA (*Ericoides*) foliis linearibus verticillatis. Lin. Sp. Plant. 195. *Phyllica* with narrow leaves growing in whorls. *Alaternoides Africana*, *ericæ foliis*, floribus albicantibus & muscosis. Hort. Amst. 2. p. 1. tab.

tab. 1. *African Bastard Alaternus, with Heath leaves and white mossy flowers.*

2. *PHYLICA (Plumosa)* foliis lineari-subulatis, summis hirsutis. Prod. Leyd. 199. *Phyllica with narrow awl-shaped leaves, which are hairy at the top.* Chamælaea foliis angustis subtus incanis, floribus capitatis muscolis. Burm. Plant. Afr. 117. tab. 43. *Spurge Olive with narrow leaves, which are hoary on their under side, and mossy flowers collected in heads.*

3. *PHYLICA (Buxifolia)* foliis ovatis sparsis. Lin. Sp. Plant. 195. *Phyllica with oval leaves growing scattering.* Chamælaea folio subrotundo subtus incano floribus in capitulum collectis. Burm. Plant. Afr. 119. tab. 44. *Spurge Olive with roundish leaves, which are hoary on their under side, and flowers collected in heads.*

The first sort grows naturally at the Cape of Good Hope, from whence it was first brought to the gardens in Holland; but it also grows naturally about Lisbon, where there are large extents of ground covered with it, in the same manner as are many lands in England covered with Heath. This is a low bushy plant, seldom rising more than three feet high; the stalks are shrubby and irregular, dividing into many spreading branches, which are again divided into smaller. The young branches are closely garnished with short, narrow, acute-pointed leaves placed in whorls round the stalks, to which they sit close; they are of a dark green, and continue all the year. At the end of every shoot, the flowers are produced in small clusters sitting close to the leaves; they are of a pure white, and begin to appear in the autumn, continuing in beauty all the winter, and decay in the spring, which renders the plant more valuable. These flowers are not succeeded by seeds in England.

The second sort grows naturally at the Cape of Good Hope, from whence it was brought to the gardens in Holland. This hath an erect shrubby stalk, which rises near three feet high, covered with a purplish bark, and here and there some white down upon it; the leaves are narrow, short, and acute-pointed, sitting close to the branches in alternate order on every side; they are thick, nervous, and of a dark green on their upper side, but hoary on their under. The flowers are collected in small heads at the end of the branches; they are white, woolly, and fringed on their borders, cut into six acute segments at the top. These appear the beginning of winter, and continue long in beauty, but are not succeeded by seeds in England.

The third sort is a native of the same country as the former; this rises with a shrubby erect stalk five or six feet high; the stalks when old, are covered with a rough purplish bark, but the younger branches have a woolly down; these are garnished with thick oval leaves about the size of those of the Box-tree; they are veined, smooth, and of a lucid green on their upper side, but are hoary on their under; they have short foot-stalks, and stand without order on the branches. The flowers are collected in small heads at the end of the branches; they are of an herbaceous colour, so make no great figure. These appear at the same time with the former.

As these plants do not produce seeds in England, so they are propagated by cuttings, which, if properly managed, will take root freely. There are two seasons for planting these cuttings; the first is the latter end of March, before the plants begin to shoot; if these are planted in pots and plunged into a very moderate hot-bed, covering them close with bell or hand-glasses, observing to shade them from the sun in the middle of the day, and to refresh them gently with water, they will put out roots in two months; then they should be inured to the open air, and after they have obtained strength, they should be carefully taken out of these pots, and each planted in a separate small pot, filled with soft loamy earth, and placed in a shady situation until they have taken new root, when they may be removed to a sheltered situation, where they may remain till autumn.

The other season for planting these cuttings is about the beginning of August; at this time they may be planted in pots, which may be either plunged into

an old hot-bed or in the ground, covering them close with bell or hand-glasses as before, and treating them in the same way; these will put out roots in about two months, but it will then be too late in the season to transplant them, so they must remain in the same pots till spring. If these are placed under a hot-bed frame in autumn, where they may be protected from the frost, and exposed to the open air in mild weather, they will succeed better than when they are more tenderly treated.

The plants are too tender to thrive in the open air in England, so they must be kept in pots and housed in winter; for although the first sort will live through the winter in a warm sheltered situation when the seasons prove favourable, yet when severe frosts happen they are always destroyed; but they require no artificial heat to preserve them, if they are sheltered under a hot-bed frame in winter when they are young, and after they are grown large kept in a green-house, where they may enjoy the free air in mild weather, and treated in the same way as other hardy exotic plants from the same country; in the summer they must be placed abroad in a sheltered situation, with which management the plants will thrive and continue several years; and as they flower in the winter, they make a good appearance in the green-house during that season.

PHYLLANTHUS. Lin. Gen. Plant. 932. Sea-side Laurel.

The CHARACTERS are,

It hath male and female flowers in the same plant; the empalements of the flower in both sexes are permanent, bell-shaped, and of one leaf, cut into six parts which spread open, and are coloured. The flowers have no petals according to some, or no empalements according to others. The male flowers have three short stamina which join at their base, but spread asunder at their top, and are terminated by twin summits. The female flowers have an angular nectarium surrounding the germen, which is roundish and three-cornered, supporting three spreading styles, crowned by obtuse stigmas. The germen afterward becomes a roundish capsule with three furrows, having three cells, each containing a single roundish seed.

This genus of plants is ranged in the third section of Linnæus's twenty-first class, which includes those plants which have male and female flowers on the same plant, and the male flowers have three stamina.

The SPECIES are,

1. *PHYLLANTHUS (Epiphanthus)* foliis lanceolatis serratis, crenis floriferis. Hort. Cliff. 439. *Phyllanthus with spear-shaped sawed leaves, having flowers growing on their edges.* Phyllanthus Americana planta, flores è singulis foliorum crenis proferens. Hort. Amst. 1. p. 199. *American Phyllanthus, with flowers growing out of every indenture of the leaves.*
2. *PHYLLANTHUS (Niruri)* foliis pinnatis floriferis, floribus pedunculatis, caule herbaceo erecto. Flor. Zeyl. 331. *Phyllanthus with winged leaves bearing flowers on foot-stalks, and an upright herbaceous stalk.* Niruri Barbadoense, folio ovali subtus glauco petiolis florum brevissimis. Martyn. Cent. 9. tab. 9. *Barbadoes Phyllanthus with an herbaceous upright stalk, and the flower-stalks very short.*
3. *PHYLLANTHUS (Emblia)* foliis pinnatis floriferis, caule arboreo, fructu baccato. Flor. Zeyl. 333. *Phyllanthus with winged leaves bearing flowers, a tree-like stalk, and berry-bearing fruit.* Nelli-Camarum. Hort. Mal. 1. p. 69.

The first sort grows naturally upon the rocks near the sea, in all the islands of the West-Indies, where the inhabitants title it Sea-side Laurel. This is seldom found growing on the land, which occasions its scarcity in Europe; for the roots strike so deep into the crevices of the rocks, as to render it almost impracticable to transplant the plants, and it is very difficult to propagate by seeds; for unless they are sown soon after they are ripe, they will not grow, and the greatest part of the seed proves abortive, so that this sort is very rare in Europe. There was formerly a plant of this sort in the gardens at Hampton-court; but this, with many other fine plants, have been destroyed by the

the ignorance of the gardeners. I also saw a fine plant of this sort in the Amsterdam Garden.

This tree grows about fifteen or sixteen feet high; the leaves come out without any order, which are five or six inches long, smooth, and thick; upon the edges of the leaves the flowers are produced, but especially toward the upper part, where they are placed very closely, so as almost to form a sort of border to the leaves; which, together with the shining green colour of the leaves, makes a very beautiful appearance: the leaves continue green all the year, which renders the plant more valuable.

It requires to be placed in a moderate stove in the winter, otherwise it will not live in England; but in summer it may be placed in the open air, in a warm sheltered situation. With this management the plant was in great vigour in the Physic Garden at Amsterdam.

The second sort grows naturally in Barbadoes, where it is a common plant; for I have many times had it come up in the tubs of earth brought from thence, with other plants: though this is an annual plant, yet the seeds being cast out of the capsules when ripe, with an elasticity, is thrown to a considerable distance, and this way the plant propagates itself in England; for the seeds being cast into the pots which are placed near it in the stove, the plants come up without farther trouble.

This rises with an herbaceous stalk a foot and a half high, garnished with many long winged leaves, composed of a great number of oval lobes, of a gray colour on their under side, but of a bright green on their upper; these lobes contract every evening, turning their under side outward; on the under side of the leaves the flowers are produced along the midrib, turning downward; these are some of them male, and others female, intermixed on the same plant, having each a bell-shaped empalement of one leaf, cut into six segments at the brim; and being coloured, the title of petals, or corolla, are by some applied to them, but others call them apetalous flowers. The male flowers have each three stamina, the female having a single style, supporting a trifid stigma, and are succeeded by roundish capsules with three cells, each containing one seed. The plant usually flowers from June to October, and the seed ripens after in succession.

The third sort grows naturally at Malabar, where it rises with a tree-like stalk to the height of twelve or fourteen feet; but in England they do not rise more than half that height, sending out from the side many patulus branches, which are garnished with very narrow winged lobes; but as it hath not produced either flowers or fruit in England, so I can give no farther account of it.

This plant is propagated by seeds, when they can be procured from the country where the plants grow naturally; these must be sown upon a hot-bed, and when the plants come up and are fit to transplant, they should be each planted into a separate small pot filled with light earth, and plunged into a hot-bed of tanners bark, being careful to shade and water them until they have taken good root; after this, the plants must constantly remain in the bark-stove, and be treated in the same manner as hath been directed for many other plants from the same country, with which the plant has been maintained several years, but has made little progress.

The other sorts, which in the former edition of this work were added to this genus, are now placed under ANDRACHNE.

PHYLLIS. Lin. Gen. Plant. 286. Bupleuroides. Boerh. Ind. alt. 71. Valerianella. Dill. Hort. Elth. 405. Simpla Nobla.

The CHARACTERS are,

The empalement of the flower is very small, composed of two leaves sitting on the germen. The flower has five obtuse spear-shaped petals, which turn backward. It hath five short hair-like stamina, which are flaccid, terminated by oblong summits. The germen, which is situated under

the flower, has no style, but is crowned by two awl-shaped, reflexed, hairy stigmas. The germen afterward turns to an oblong angular fruit, containing two parallel seeds, convex on their outside, plain on the other, and broad at the top.

This genus of plants is ranged in the second section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and two styles or stigmas.

We have but one SPECIES in the English gardens at present, viz.

PHYLLIS (Nobla) stipulis dentatis. Prod. Leyd. 92. *Phyllis with indented stipulæ.* Bupleuroides quæ simpla nobla Canariensium. Pluk. Boerh. Ind. alt. 1. p. 72. *Bastard Hare's-ear, or Simpla Nobla of the Canaries.*

This plant grows naturally in the Canary Islands, from whence the seeds were formerly brought to England. It rises with a soft shrubby stalk about two or three feet high, which is seldom thicker than a man's finger, of an herbaceous colour, and full of joints. These send out several small side branches toward the top, garnished with spear-shaped leaves near four inches long, and almost two broad in the middle, drawing to a point at each end; they are of a lucid green on their upper side, but pale on their under, having a strong whitish midrib, with several deep veins running from it to the sides; the leaves are for the most part placed by threes round the branches, to which they sit close. The flowers are produced at the end of the branches, in loose panicles; they are small, of an herbaceous colour at their first appearance, but before they fade, change to a brown or worn-out purple, and are cut into five parts to their base, where they are connected, and fall off without separating, so should be termed a flower of one petal. These segments are reflexed backward so as to cover the germen, which is situated under the flower, and afterward becomes a short, turbinate, obtuse, angular fruit, which splits in two parts when ripe, each containing one seed, flat on the inside, convex on the outside and angular. This plant flowers in June, and the seeds ripen in autumn.

It is propagated by seeds, which must be sown on a bed of fresh light earth toward the end of March, and the plants will come up by the beginning of May; when they are fit to transplant, they should be put into separate pots, and placed in a shady situation until they have taken root; after which time they should be placed in a sheltered situation, where they may have the morning sun, and in the summer will require to be frequently watered. In winter they must be sheltered from the frost, but require to have as much free air as possible in mild weather; the second year the plants will flower, so if in the spring some of the plants are shaken out of the pots and put into the full ground, they will perfect their seeds much better than those which remain in the pots.

As these plants seldom continue in health above four or five years, it will be proper to raise a supply of young plants to succeed them.

The plants retain their leaves all the year, which, being large and of a shining green, make a handsome appearance in winter, in which the beauty of it consists, for the flowers have none.

PHYSALIS. Lin. Gen. Plant. 223. Alkekengi. Tourn. Inst. R. H. 150. tab. 64. Winter Cherry.

The CHARACTERS are,

The flower hath a small swelling permanent empalement of one leaf, which is five-cornered, and cut at the top into five acute points. The flower hath one wheel-shaped petal, with a short tube and a large brim, which is five-cornered and plaited. It has five small awl-shaped stamina which join together, terminated by erect summits, and a roundish germen supporting a slender style, crowned by an obtuse stigma. The germen afterward turns to an almost globular berry with two cells, inclosed in the large inflated empalement, and is filled with compressed kidney-shaped seeds.

This genus of plants is ranged in the first section of Linnaeus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. *PHYSALIS (Alkekengi)* foliis geminis integris acutis, caule herbaceo inferne subramoso. Lin. Sp. Plant. 262. *Physalis with two leaves at a joint, which are sharp-pointed, and an herbaceous stalk which branches at bottom.* Alkekengi officinarum. Tourn. Inst. R. H. 151. *The common or officinal Winter Cherry.*
2. *PHYSALIS (Viscosa)* foliis geminis repandis obtusis subtomentosis, caule herbaceo superne paniculato. Lin. Sp. 261. *Winter Cherry with leaves growing by pairs, which are obtuse, a little woolly, and an herbaceous stalk.* Alkekengi Bonariensis repens, baccâ turbinatâ viscosâ. *Creeping Winter Cherry of Buenos Ayres, with a viscous turbinated berry.*
3. *PHYSALIS (Pennsylvanica)* radice perenni, caule procumbente, foliis ovatis acutè dentatis, petiolis longissimis. *Physalis with a perennial root, a trailing stalk, and oval leaves which are acutely indented, and have very long foot-stalks.* Alkekengi Virginianum perenne majus, flore luteo amplo, fructu minimo. Rand. Act. Phil. N° 399. *Greater perennial Virginia Winter Cherry, with a large yellow flower and a small fruit.*
4. *PHYSALIS (Virginiana)* caule herbaceo, foliis ovato-lanceolatis acutè dentatis. tab. 206. fig. 1. *Winter Cherry with an herbaceous stalk, and oval spear-shaped leaves which are acutely indented.*
5. *PHYSALIS (Curassavica)* caule suffruticoso, foliis ovatis tomentosis integerrimis. *Physalis with a shrubby stalk, and oval downy leaves which are entire.* Alkekengi Curassavicum, foliis origani incanis, flore viète sulphureo, fundo purpureo. Boerh. Ind. alt. 2. p. 66. *Winter Cherry of Curassao with hoary Origan leaves, and a rusty sulphur-coloured flower with a purple bottom.*
6. *PHYSALIS (Somnifera)* caule fruticoso, ramis rectis, floribus confertis. Lin. Sp. Plant. 180. *Physalis with a shrubby stalk, erect branches, and flowers growing in clusters.* Alkekengi fructu parvo verticillato. Tourn. Inst. 151. *Winter Cherry with a small fruit growing in whorls.*
7. *PHYSALIS (Flexuosa)* caule fruticoso, ramis flexuosis, floribus confertis. Lin. Sp. Plant. 182. *Physalis with a shrubby stalk, flexible branches, and flowers growing in clusters.* Baccifera Indica, floribus ad foliorum exortus, fructu sulcato decapireno. Raii Hist 1632. *Indian berry-bearing Plant, with flowers coming out from the foot-stalks of the leaves, and a furrowed fruit containing ten seeds.*
8. *PHYSALIS (Arborescens)* foliis ovato-lanceolatis integerrimis oppositis, caule fruticoso. tab. 206. fig. 2. *Physalis with oval, spear-shaped, entire leaves which are placed opposite, and a shrubby stalk.* Alkekengi Americanum arborescens, fructu sphaerico rubro, vesicâ atro-purpureâ. Houst. MSS. *Tree American Winter Cherry, with a red spherical fruit and a deep purple-coloured bladder.*
9. *PHYSALIS (Ramosa)* ramosissima, foliis villosis viscosis floribus pendulis. Lin. Sp. Plant. 262. *The most branching Physalis with hairy viscous leaves, and nodding flowers.* Alkekengi Virginianum fructu luteo. Tourn. Inst. 151. *Virginia Winter Cherry with a yellow fruit.*
10. *PHYSALIS (Angulata)* ramosissima, ramis angulatis glabris, foliis ovatis dentatis. Lin. Sp. Plant. 262. *The most branching Physalis with angular smooth branches.* Alkekengi Indicum majus. Tourn. Inst. 151. *Greater Indian White Cherry.*
11. *PHYSALIS (Minima)* ramosissima, foliis ovatis acuminatis subdentatis petiolis longioribus. *Very branching Physalis, with oval acute-pointed leaves which are somewhat indented, and have longer foot-stalks.* Alkekengi Indicum minimum, fructu virescente. Tourn. Inst. 151. *The least Indian Winter Cherry with a greenish fruit.*
12. *PHYSALIS (Patula)* ramosissima patula, ramis angulatis glabris, foliis lanceolatis pinnato-dentatis. *The most branching spreading Physalis, with smooth angular branches, and spear-shaped leaves which are indented like wings.*

13. *PHYSALIS (Villosa)* ramosissima, ramis villosis, foliis ovatis acuminatis serrato-dentatis. *The most branching Physalis with hairy branches, and oval acute-pointed leaves, which are indented like a saw.* Alkekengi Americanum, annuum, ramosissimum, villosum, fructu rotundo ex luteo virescente. Houst. MSS. *The most branching, annual, hairy, American Winter Cherry, with a round, yellowish, green fruit.*

14. *PHYSALIS (Cordata)* caule erecto ramoso, foliis ovatis serrato-dentatis, petiolis pedunculisque longissimis. *Physalis with an erect branching stalk, oval, indented, sawed leaves, and the foot-stalks of the leaves and flowers very long.* Alkekengi Americanum annuum, lamii folio, fructu cordato. Houst. MSS. *Annual American Winter Cherry, with a dead Nettle leaf and a heart-shaped fruit.*

15. *PHYSALIS (Maxima)* caule erecto ramoso, foliis ovato-lanceolatis viscosis, fructu maximo cordato. *Physalis with an erect branching stalk, oval, spear-shaped, viscous leaves, and a large heart-shaped fruit.* Alkekengi Americanum annuum, maximum viscosum. Houst. MSS. *The largest, annual, viscous, American Winter Cherry.*

16. *PHYSALIS (Peruviana)* caule erecto ramoso, ramis angulatis, foliis sinuatis, calycibus acutangulis. *Physalis with an erect branching stalk, angular branches, sinuated leaves, and empalements having acute angles.* Alkekengi amplo flore violaceo. Feuill. Obs. 724. tab. 16. *Winter Cherry with a large Violet-coloured flower.*

The first sort is the common Winter Cherry which is used in medicine; this grows naturally in Spain and Italy, but has been long cultivated in the English gardens. The roots of this are perennial, and creep in the ground to a great distance, if they are not confined; these shoot up many stalks in the spring, which rise about a foot high or better, and are garnished with leaves of various shapes; some are angular and obtuse, others are oblong and acute-pointed, of a dark green, and generally there are two leaves coming out from the same point on the same side of the stalk; they have long foot-stalks. The flowers are produced from the wings of the stalks, standing upon slender foot-stalks, having one white petal which has a short tube, and is cut at the brim into five angles spreading open. In the center of the tube is situated a roundish germen, supporting a slender style crowned by an obtuse stigma; this is accompanied by five stamina of the same length, terminated by oblong, erect, yellow summits which join together. The flowers appear in July, and are succeeded by round berries about the size of small Cherries, inclosed in an inflated bladder, which turns red in the autumn, when the top opens, and discloses the red berry, which is soft, pulpy, and filled with flat kidney-shaped seeds. Soon after the fruit is ripe, the stalks decay to the roots.

This plant is easily propagated, either by seeds or parting the roots; the latter being the most expeditious method is generally practised. These roots may be transplanted and parted, any time after the stalks decay, till the roots begin to shoot in the spring; they love a shady situation, and should be confined, otherwise they will ramble to a great distance in one year, and when the stalks stand at a distance they make no appearance. Their only beauty is in autumn, when the fruit is ripe, at which time their red bladders opening and disclosing the Cherry-shaped fruit, make a pretty appearance.

The leaves of this plant are cooling, and of the nature of common Nightshade; the berries are a singular good diuretic, and useful against the gravel and stone. There has been several instances of their great virtue in bringing away great quantities of gravel, when other remedies have been tried without success. The berries boiled in milk, and sweetened with sugar, cure the heat of the urine, making bloody water, and ulcers in the kidneys and bladder.

The second sort grows naturally at Buenos Ayres; this hath a creeping root, by which it multiplies very fast, sending up a great number of smooth stalks about a

P H Y

foot high, which divide toward their top into small spreading branches, garnished with heart-shaped or oval leaves, about three inches long, and two broad near their base; they are entire and rough to the touch, of a pale yellowish green, standing upon pretty long foot-stalks placed alternately. The flowers come out from the wings of the stalks toward the top, and have long slender foot-stalks; they are of a dirty yellow colour with purple bottoms. They appear in June and July, and are succeeded by viscous berries about the size of the common sort, of an herbaceous yellow colour, inclosed in a swelling bladder, of a light green colour.

This plant is easily propagated by parting the roots either in spring or autumn, but it is too tender to live abroad through the winter in England, so they should be planted in pots, and sheltered under a hot-bed frame in winter, where they may enjoy the free air at all times in mild weather.

The seeds of the third sort were sent me from Virginia, where the plant grows naturally; this hath a perennial root and an annual stalk, but these roots do not creep in the ground like the two former. The stalks of this grow two feet long, and spread on the ground if they are not supported; these are garnished with oval leaves three inches long, and two inches and a half broad, standing alternately upon very long foot-stalks; they are of a pale green, having several acute indentures on their edges. The flowers come out from the wings of the stalk upon very short foot-stalks; they are larger than those of the common sort, and of a pale yellow colour. These are succeeded by very small yellowish berries which ripen in the autumn, when the season proves warm, but in cool moist summers they seldom ripen here.

This sort is propagated by seeds, which should be sown upon a warm border about the latter end of March; and when the plants come up, they should be thinned where they are too close, and kept clean from weeds till autumn, when they should be transplanted to the places where they are to remain, which should be in a warm situation, where they will live through the winter in mild seasons, but are killed by severe frost if they are not screened.

The seeds of the fourth sort were sent me from Philadelphia by Dr. Bensil, who found the plants growing there naturally. This hath a perennial root composed of strong fibres, from which arise two or three hairy stalks about nine or ten inches high, dividing into several branches which are garnished with oval spear-shaped leaves, of a pale green and hairy, about two inches and a half long, and an inch and a half broad, having several acute indentures on their edges, and stand alternately upon short foot-stalks. The flowers come out from the side of the branches, at the base of the foot-stalks of the leaves; these have long slender foot-stalks; the flowers have very short tubes, which are larger than in most of the species of this genus; they are of a sulphur colour, with a dark purple bottom. These appear in July, and in warm seasons are succeeded by oval yellowish berries, which ripen in the autumn. This sort may be propagated by seeds in the same way as the third, and the plants require the same treatment.

The fifth sort grows naturally at Curassao in the West-Indies. This hath a perennial creeping root, from which arise several slender stalks about a foot high, which become somewhat ligneous, but seldom last above two years, the leaves standing alternately upon short foot-stalks; they are about two inches long, and an inch and a half broad. The flowers come out from the wings of the stalk toward the top, standing upon short slender foot-stalks; these are garnished with oval downy petals, which are small, of a sulphur colour, and have dark purple bottoms. They appear in July and August, but are rarely succeeded by berries in England.

This is easily propagated by parting the roots in the spring, but the plants are too tender to live through the winter in England without artificial warmth, so

P H Y

the pots should be placed in a moderate warmth in winter; but during the months of July, August, and September they may be placed in the open air in a warm situation.

The sixth sort grows naturally in Crete, Sicily, and Spain. This rises with a shrubby stalk near three feet high, dividing into several branches which grow erect, and are covered with a woolly down, garnished with oval spear-shaped leaves almost three inches long, and one and a half broad in the middle; they are downy, and stand upon short foot-stalks. The flowers come out in clusters on the side of the branches; they are small, of an herbaceous white colour, sitting very close to the branches, and are succeeded by small berries almost as large as those of the first sort, which when ripe are red. This flowers in June and July, and the berries ripen in autumn.

This plant is propagated by seeds, which may be sown on a bed of light earth the beginning of April, and when the plants are two or three inches high, they should be carefully taken up, and each planted in a separate small pot filled with earth out of a kitchen-garden, and placed in the shade till they have taken new root; then they may be removed to a sheltered situation, where they may remain till the beginning of October; at which time they should be removed into the green-house, for the plants are too tender to live through the winter in the open air, so they must be treated like the other green-house plants, but should be sparingly watered in winter. These plants will continue several years if they are not too tenderly treated.

The seventh sort grows naturally at Malabar, and also at the Cape of Good Hope. This rises to the height of five or six feet, sending out long flexible branches covered with a gray bark, and garnished with oblong oval leaves which are often placed opposite, and sometimes by threes round the branches, to which they sit close. The flowers are produced in clusters at the base of the foot-stalks of the leaves; they are small, and of an herbaceous yellow colour; these are succeeded by round purplish berries having ten cells, each including one seed. This plant flowers in July and August, but unless the season is warm, the berries do not ripen in England.

This is propagated by seeds, which should be sown upon a moderate hot-bed, and when the plants have four leaves, they should be transplanted on a fresh hot-bed, observing to shade them from the sun till they have taken new root; then they should have fresh air admitted to them every day in warm weather to prevent their drawing up weak, and should be treated in the same way as other exotic plants. When these are grown three or four inches high, they should be carefully taken up, and each planted in a separate small pot, filled with light loamy earth, and placed in a frame upon an old hot-bed, shading them from the sun till they have taken new root; then they should be gradually inured to bear the open air, into which they should be removed in July, and placed in a warm situation, where they may remain till the end of September; then they should be removed into shelter, and the first winter they should be placed in a moderate stove; but when the plants have obtained strength, they will live through the winter in a good green-house.

The eighth sort was discovered by the late Dr. Houstoun growing naturally at Campeachy, from whence he sent the seeds to England. This hath a shrubby stalk which rises ten or twelve feet high, dividing toward the top into several small branches, covered with a gray hairy bark, and garnished with oval spear-shaped leaves; those on the lower part are placed alternately, but toward the end of the branches they are opposite. The lower leaves are from three to four inches long, and two broad in the middle, drawing to a point at both ends; they are of a pale green, and are downy. The flowers come out from the wings of the stalks toward the end of the branches, sometimes one, and at other times two are produced at the same joint opposite;

opposite; they stand upon short nodding foot-stalks. The flowers are small, of a pale dirty yellow colour, having purple bottoms; these are succeeded by small, spherical, red berries included in an oval, dark, purple bladder. It flowers in June and July, but unless the season proves warm, there are no berries succeeding them.

This may be propagated by seeds in the same way as the last-mentioned, and the plants require the same treatment, but are not so hardy, therefore they must be kept in a moderate stove in winter; but in the middle of summer, they should be placed in the open air in a sheltered situation for about three months; for if they are constantly kept in the stove, they will draw up weak, so will not flower. It may also be propagated by cuttings, which, if planted in pots during the spring and summer months, and plunged into a gentle warmth, will take root freely, and may be treated in the same way as is before directed for the sixth sort.

The ninth sort is an annual plant, which grows naturally in Virginia. This branches out very wide close to the ground, and the branches frequently lie upon it; they are angular and full of joints, dividing again into smaller branches, and are garnished with hairy viscous leaves, which are almost heart-shaped, standing upon pretty long foot-stalks; they are about three inches long and almost two broad, having several acute indentures on their edges. The flowers are produced on the side of the branches upon short, slender, nodding foot-stalks; they are of an herbaceous yellow colour with dark bottoms; these are succeeded by large swelling bladders of a light green, inclosing berries as large as common Cherries, which are yellowish when ripe. This sort flowers in June and July, and the berries ripen in the autumn.

If the seeds of this sort are permitted to scatter, the plants will come up in the spring, and require no other care but to thin them, and keep them clean from weeds; or if the seeds are sown in the spring on a common border, the plants will rise very well, and need no other care.

The tenth sort is also an annual plant, which grows naturally in the islands of the West-Indies; this rises with an upright branching stalk from two to three feet high. The branches are smooth, angular, and garnished with spear-shaped leaves ending in acute points, which are sharply indented on their edges. The flowers come out toward the end of the branches upon short slender foot-stalks; they are very small, of a dirty white colour, and are succeeded by berries the size of common Cherries, covered with an angular bladder; they are of a yellowish colour when ripe.

This sort is propagated by seeds, which should be sown on a moderate hot-bed, and when the plants come up and are a little advanced, they should be planted on a fresh hot-bed to bring them forward, and treated in the same way as the Capsicum. When they are grown strong, and are hardened to bear the open air, they may be transplanted with balls of earth to their roots into a warm border, observing to water and shade them till they have taken root; after which they will require no other care, but to keep them clean from weeds.

The eleventh sort grows naturally in the West-Indies; this is an annual plant with very branching stalks, which seldom rise above a foot high. The leaves are oval, of a deep green, and have long foot-stalks; the flowers are small, white, and stand upon short foot-stalks; the berries are small, and green when ripe.

The twelfth sort was discovered by the late Dr. Houstoun growing naturally at La Vera Cruz; this is a low annual plant, with a very branching spreading stalk. The leaves are spear-shaped, downy, and have deep indentures on their edges, which are opposite and regular like a winged leaf; the branches are smooth and angular; the flowers small and white; the fruit is small, and yellowish when ripe.

The thirteenth sort was discovered by the late Dr.

Houstoun at La Vera Cruz; this is an annual plant with a very branching hairy stalk. The leaves are oval, acute-pointed, and indented like a saw on their edges; the flowers are small, and of a pale yellow colour; the fruit is round, as large as a Cherry, and of a yellowish green when ripe.

The fourteenth sort was discovered at La Vera Cruz by the same gentleman; this is an annual plant, with an upright branching stalk near two feet high, garnished with oval leaves, indented on their edges like a saw. They have long foot-stalks, and change to a purplish colour in the autumn. The flowers are small and white, standing upon very long foot-stalks, and are succeeded by large berries almost as large, and of the shape of Heart-Cherries, of a yellowish green, with some purple stripes.

The fifteenth sort was found by the same gentleman, growing naturally in the same country; this is an annual plant, with a smooth, erect, branching stalk near three feet high, garnished with oval, spear-shaped, viscous leaves, standing on long foot-stalks. The flowers are of a pale yellow, and small; these are succeeded by large heart-shaped fruit, of a pale yellow when ripe. The five last mentioned sorts are propagated by seeds in the same manner as the eleventh, and the plants require the same treatment.

The sixteenth sort grows naturally in Peru, from whence the younger de Jussieu sent the seeds. This is an annual plant, rising with a strong, herbaceous, angular stalk four or five feet high, of a purplish colour, dividing into several branches which are angular, and spread out wide on every side; these are garnished with oblong leaves which are deeply sinuated on their sides, and are of a deep green. The foot-stalks of the flowers are short; the empalement of the flower is large, bell-shaped, and deeply cut into five segments; the flower is large, of the open bell-shape, of a light blue colour, and is succeeded by berries about the size of common Cherries, inclosed in a large swelling bladder, having five sharp angles. It flowers in July, and the seeds ripen in the autumn, which if permitted to scatter, the plants will come up the following spring; or if the seeds are sown on a bed of rich earth in the spring, the plants will rise easily, and may be afterward transplanted to the borders of the pleasure-garden, where they must be allowed room, for if the ground is good, the plants will grow very large.

Father Feuile, who first discovered this plant in Peru, and has given a figure and description of it, recommends it greatly for its virtues, and says, the Indians make great use of its berries to bring away gravel, and to relieve persons who have a stoppage of urine, and gives the manner of using them; which is, to bruise four or five of the berries either in common water, or white wine, giving it to the patient to drink, and the success is astonishing.

PHYTOLACCA. Tourn. Inst. R. H. 299. tab. 154. Lin. Gen. Plant. 521. [This plant is so called of *φυτόν*, a plant, and *Lacca*, a colour, because a red coloured lacca is made thereof.] American Nightshade.

The CHARACTERS are,

The flower hath no petals according to some, or no empalement according to others, for the cover of the parts of generation being coloured, is by the latter termed petals; there are five of these which are roundish, concave, spreading open, and permanent. It has for the most part ten stamina which spread open, and are the same length as the petals, terminated by roundish summits, and ten compressed orbicular germen joined together on their inside, but are divided on their outside, upon which sit ten very short styles which are reflexed, and crowned by single stigmas. The germen afterward turns to an orbicular depressed berry, with ten longitudinal deep furrows, having ten cells, each containing a single smooth seed.

This genus of plants is ranged in the fifth section of Linnæus's tenth class, which includes those plants whose flowers have ten stamina and ten styles.

The

The SPECIES are,

1. PHYTOLOACCA (*Vulgaris*) floribus decandris decagynis. Hort. Cliff. 117. *Phytolacca with flowers having ten stamina and ten styles. Phytolacca Americana, majori fructu. Tourn. Inst. 229. American Nightshade with large fruit, commonly called Virginian Poke, or Porke Physic.*
2. PHYTOLOACCA (*Mexicana*) foliis ovato-lanceolatis, floribus sessilibus. *Phytolacca with oval spear-shaped leaves, and flowers sitting close to the stalks. Phytolacca Mexicana, baccis sessilibus. Hort. Elth. 318. Mexican Phytolacca, whose berries grow close to the stalk.*
3. PHYTOLOACCA (*Icosandra*) floribus icolandris decagynis. Lin. Sp. 631. *Phytolacca with many stamina, which are fixed to the receptacle. Phytolacca spicis florum longissimis, radice annua. tab. 207. Phytolacca with the longest spikes of flowers, and an annual root.*
4. PHYTOLOACCA (*Dioica*) floribus dioicis, caule arboreo ramosa. *Phytolacca with a tree-like stem, which has male and female flowers on different plants.*

The first sort grows naturally in Virginia, and also in Spain and Portugal; this hath a very thick fleshy root, as large as a man's leg, divided into several thick fleshy fibres, which run deep in the ground. When the roots are become large, they send out three or four stalks, which are herbaceous, as large as a good walking-stick, of a purple colour, and rise the height of six or seven feet, dividing into many branches at the top, garnished with leaves about five inches long, and two inches and a half broad; they are rounded at their base, but terminate in a point, and are placed without order, having short foot-stalks; they are of a deep green, and in the autumn change to a purplish colour before they fall off. From the joints of the branches and at their divisions, come out the foot-stalks of the flowers, which are about five inches long; the lower part is naked, but the upper half sustains a number of flowers ranged on each side like common Currants. Each flower stands upon a foot-stalk half an inch long; the flowers have five purplish petals, within which stand the ten stamina and styles. After the flowers are faded, the germen turns to a depressed berry with ten furrows, having ten cells, filled with smooth seeds. It flowers in July and August, and in warm seasons the berries ripen in autumn.

It may be propagated by sowing the seeds in the spring upon a bed of light earth, and when the plants come up, they should be transplanted into the borders of large gardens, allowing them space to grow, for they must not be planted too near other plants, lest they overbear and destroy them, as they grow to be very large, especially if the soil is good. When they have taken root, they will require no farther care but only to clear them from weeds, and in the autumn they will produce their flowers and fruit; but when the frost comes on, it will cut down the stems of these plants which constantly decay in the winter, but their roots will abide in the ground, and come up again the succeeding spring.

The roots of this plant will continue many years, especially if they are planted in a dry soil, for wet in winter standing about the roots will cause them to rot; and sometimes the frost in very severe winters will kill them, if the surface of the ground is not covered with mulch, but in our ordinary winters they are never injured.

Parkinson says, that the inhabitants of North America make use of the juice of the root as a familiar purge; two spoonfuls of the juice will work strongly. Of late there have been some quacks, who pretend to cure cancers with this herb, but I have not met with one instance of its having been serviceable in that disorder. The inhabitants of North America boil the young shoots of this plant, and eat it like Spinach. The juice of the berries stain paper and linen of a beautiful purple colour, but it will not last long. If there could be a method of fixing the dye, it might be very useful.

The vigneron in Portugal, for many years made use of the juice of the berries of this plant to mix with

their red port wines when they made it, which gave a deep colour to the wine; and when there was too much of this juice added, it gave a very disagreeable taste to the wine; and complaint of this practice having been communicated to his Portuguese Majesty, he gave orders that the stems of the Phytolacca should be cut down and destroyed before they produced berries, to prevent the use of this juice for the future, in order to gain a better reputation to the wine of that country. Some of this unmixed wine I have drank; and found it much more palatable and lighter than any port wine I had ever before tasted; but whether this is still continued in that country, I cannot say.

The second sort grows naturally in the Spanish West-Indies; the late Dr. Houstoun found it growing in great plenty at La Vera Cruz, where the inhabitants constantly used it for their table. This plant is biennial, seldom continuing longer than two years; and when it flowers and produces plenty of seeds the first year, the plants frequently die before the following spring. This hath an herbaceous stalk about two feet high, about the size of a man's finger, dividing at the top into two or three short branches, garnished with oval-spear-shaped leaves near six inches long, and almost three broad, drawing to a point at each end; they have a strong longitudinal midrib, and several transverse veins running from that to the sides, of a deep green, and have foot-stalks an inch and a half long, placed without order on the stalk. The foot-stalks of the flowers come out from the side of the branches opposite to the leaves; they are seven or eight inches long; the lower part, about two inches in length, is naked; the remaining part is garnished with white flowers sitting close to the stalks, which are white, having a blush of purple in the middle, each being cut into five segments almost to the bottom, and have from eight to fourteen stamina, and ten styles in each flower, which are succeeded by flat berries, having ten deep furrows divided into so many cells, each containing one or two smooth seeds. This flowers in July and August, and the seeds ripen late in the autumn.

The third sort grows naturally in Malabar, from whence I received the seeds; this plant is annual, always perishing soon after it has perfected seeds, so that in this particular it differs greatly from the first; this rises with an herbaceous stalk from two to three feet high, which has several longitudinal furrows, and changes the latter part of summer to a purplish colour. It divides at the top into three or four branches, garnished with spear-shaped leaves six or seven inches long, and almost three broad in the middle, drawing to a point at each end; they are of a deep green, and have short foot-stalks; sometimes they stand alternately, at others they are placed opposite, and are frequently oblique to the foot-stalk. The foot-stalks of the flowers come out from the side of the branches opposite to the leaves; they are nine or ten inches long, the lower part being naked as in the other sorts, but this is much shorter than the other species; the other part is garnished with larger flowers than those of the other sorts; they are white on their inside, of an herbaceous colour on their edges, and purplish on their outside, standing upon short foot-stalks; these have not always the same number of stamina, some of them have but eight, and others nine or eleven, which are terminated by roundish summits. These flowers are succeeded by orbicular, compressed, soft berries divided by deep furrows on their outside into ten cells, each containing one smooth shining black seed; the racemus of flowers is very narrow at the top, where it is commonly inclined. This flowers in July and August, and the seeds ripen in the autumn, soon after which the plant decays.

The berries of this sort are very succulent, and their juice stains paper and linen of a beautiful purple colour, but it is not permanent.

These two sorts are not so hardy as the first, so their seeds should be sown upon a moderate hot-bed in the spring, and when the plants are fit to remove, they should

should be transplanted to another hot-bed to bring them forward, observing to shade them from the sun till they have taken new root; after which they should be treated in the same way as other tender exotic plants, and the beginning of July they may be transplanted out upon a warm border, or into pots filled with light rich earth, and shaded from the sun till they have taken new root; after which they will require to be duly watered in dry weather, and kept clean from weeds. As these plants perfect their seeds every autumn, they may be easily preserved.

The fourth sort grows naturally in Mexico, from whence the seeds were sent to Paris some years past, and they have been sent to Spain many years since; for there are growing in some of the gardens, several trees which are now upward of twenty feet high; and I have been credibly informed, there are some of the trees which produce male, and others female flowers only; but as the plant in the Chelsea Garden has not as yet produced any flowers which have opened perfectly, so I cannot from my own observations determine this.

The plant hath a strong woody stem as large as a man's leg, which sends out many irregular branches, garnished with oval spear-shaped leaves six inches long, and almost three broad, having large midribs, which are of a purple colour when the leaves are fully grown; the flowers are produced at the base of the foot-stalks of the leaves, in a racemus like those of the other species; but as those on the plant in the Chelsea Garden were produced late in the season, so they dropped off before they opened.

This species may be propagated by cuttings during the summer months, which should be planted in pots filled with light earth and plunged into a moderate hot-bed, covering the pots with hand-glasses to exclude the air from the cuttings, and duly shading them from the sun; in about five or six weeks they will put out roots, when they may be each planted into a separate small pot, and plunged into the bed again, shading them daily till they have taken new root; then they should be gradually inured to the open air, where they may remain till the end of September, when they must be removed into a moderate stove for the winter season, for they will not live through the winter in a green-house, unless it is a very warm one.

P I E R C E A. Solanoides. Tourn. Aët. Par. 1706.

The CHARACTERS are,

The flower has no petals; the empalement which incloses the parts of generation is composed of four oblong, oval, coloured leaves, which are by some called petals. It hath four stamina, which stand erect and close together, terminated by small summits. In the center is situated a large roundish germen, supporting a short style, crowned by an obtuse stigma. The germen afterward turns to a roundish berry sitting upon the reflexed empalement, having one cell, inclosing a rough seed of the same form.

I have taken the freedom of inscribing this genus of plants to his Grace the Duke of Northumberland, who is not only a great encourager of botanical studies, but greatly skilled in the science himself.

Tournefort first placed this with the Phytolacca, making it a species of that genus; but as the flowers of Phytolacca have five petals or leaves to the empalement, and ten stamina, and the flowers of this have but four petals and eight stamina, and the berries of Phytolacca have ten cells, and these have but one, so they could not with propriety be joined together; therefore upon mature consideration Tournefort constituted a new genus of it, by the title of Solanoides, and published the characters in the Memoirs of the Academy of Sciences for the year 1706; but as all those titles of plants which end with oides, have been by later botanists changed, so I shall join this to the first section of Linnæus's eighth class, who has supposed this to be the same with Plumier's Rivinia, so he has applied that title to this plant, and believed Plumier was mistaken when he drew eight stamina to the flower; but Plumier's Rivinia is totally different

from this plant, and the flowers of it have eight stamina as Plumier has represented it.

The SPECIES are,

1. PIERCEA (*Glabra*) foliis ovato-lanceolatis glabris. *Piercea with oval, spear-shaped, smooth leaves.* Solanoides Americana, circaeæ foliis glabris. Tourn. Aët. Par. 1706. *American Solanoides with smooth Enchanters Nightshade leaves.*

2. PIERCEA (*Tomentosa*) foliis cordatis pubescentibus. *Piercea with heart-shaped downy leaves.* Solanoides Americana circaeæ foliis canescentibus. Tourn. Aët. Par. 1706. *American Solanoides with hoary leaves like Enchanters Nightshade.*

These plants grow naturally in most of the islands in the West-Indies, but the first is the most common there. This rises with a slender herbaceous stalk three or four feet high, and by age becomes a little ligneous at the bottom. It divides into many branches which are herbaceous, and have angles; these are garnished with oval spear-shaped leaves near four inches long, and two broad in the middle; they are of a bright green, and have slender foot-stalks an inch and a half broad. The foot-stalks of the flowers come out from the side of the branches, at the base of the foot-stalks of the leaves; they are from four to five inches long, sustaining a great number of small white flowers, ranged along the upper part on both sides. These are succeeded by small red berries full of a red juice, inclosing one hard seed of the same form.

There is a succession of flowers upon this plant most part of the year, which are succeeded by berries ripening after each other, so that the plants are seldom destitute of them; and although the flowers make but a small appearance, yet the long bunches of bright red berries, hanging on all the branches great part of the year, have a fine effect.

The second sort grows taller than the first, and the branches grow more erect; the leaves are smaller, heart-shaped, and covered with short hairy down; the spikes of flowers are not so long, and the flowers are not so closely placed together, and have longer foot-stalks. This continues flowering and producing ripe fruit in the same manner as the other, most part of the year.

These plants are propagated by seeds, which should be sown soon after they are ripe, for if they are kept long out of the ground they seldom grow the same year. They should be sown in pots filled with light earth, and plunged into a moderate hot bed; and when the plants come up, they should be kept clean from weeds, and gently watered as the earth becomes dry. When the plants are two inches high, they should be each planted in a small halfpenny pot filled with light earth, and plunged into a moderate hot-bed, observing to shade them till they have taken new root; after which they must be treated in the same way as other exotic plants, by admitting fresh air to them daily, according to the warmth of the season, and giving them water as often as they require it. When the plants have obtained strength, they should be removed into the stove, and may be placed on shelves, and there they must constantly remain, for they are too tender to thrive in the open air in England in the warmest part of the year.

The juice of the berries of these plants will stain paper and linen of a bright red colour, and I have made many experiments with it to colour flowers, which have succeeded extremely well; these were made in the following manner. I pressed out the juice of the berries, and mixed it with common water, putting it into a phial, shaking it well together for some time, till the water was thoroughly tinged; then I cut off the flowers which were just fully blown, and placed their stalks into the phial, and in one night the flowers have been finely variegated with red. The flowers which I made the experiments on were the Tuberosc and the double white Narcissus.

P I L O S E L L A. See HIERACIUM.

PIMPINELLA. Lin. Gen. Plant. 328. Tragofelinum. Tourn. Inst. R. H. 309. tab. 163. Burnet Saxifrage; in French, *Boucage*.

The CHARACTERS are,

It hath an umbellated flower; the principal umbel is composed of many rays or smaller umbels; neither of these have any involucrum, and the empalements are scarce visible; the greater umbel is uniform. The flowers have five heart-shaped inflexed petals, which are nearly equal, and five stamina which are longer than the petals, terminated by roundish summits. The germen is situated under the flower, supporting two short styles, crowned by obtuse stigmas. The germen afterward becomes an oblong oval fruit, divided in two parts, containing two oblong seeds, plain on the inside and convex on the other, and furrowed.

This genus of plants is ranged in the second section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and two styles.

The SPECIES are.

1. **PIMPINELLA (Major)** foliis pinnatis, foliolis cordatis serratis, summis simplicibus trifidis. Burnet Saxifrage with winged leaves near the root, having heart-shaped sawed lobes, and single three-pointed leaves at the top of the stalk. Tragofelinum majus, umbellâ candidâ. Tourn. Inst. R. H. 309. Greater Burnet Saxifrage with a white umbel.
2. **PIMPINELLA (Saxifraga)** foliis pinnatis, foliolis radicalibus subrotundis, summis linearibus. Lin. Sp. Plant. 263. Burnet Saxifrage with winged leaves, those at the bottom having lobes which are roundish, but those at the top linear. Tragofelinum alterum majus. Tourn. Inst. R. H. 309. Another greater Burnet Saxifrage.
3. **PIMPINELLA (Hircina)** foliis pinnatis, foliolis radicalibus pinnatifidis, summis linearibus trifidis. Burnet Saxifrage with winged leaves, whose lobes of the bottom leaves are wing-pointed, and the upper ones linear and trifid. Tragofelinum minus. Tourn. Inst. R. H. Lesser Burnet Saxifrage.
4. **PIMPINELLA (Nigra)** foliis pinnatis hirsutis, foliolis radicalibus cordatis inæqualiter serratis, summis linearibus quinquefidis. Burnet Saxifrage with hairy winged leaves, whose lobes of the bottom leaves are heart-shaped, unequal and sawed, the upper ones linear and five-pointed. Tragofelinum radice nigra Germanicum. Jussieu. Hort. Chelf. Cat. 100. German Burnet Saxifrage with a black root.
5. **PIMPINELLA (Austriaca)** foliis pinnatis lucidis foliolis radicalibus lanceolatis, pinnato serratis, summis linearibus pinnatifidis. Burnet Saxifrage with shining winged leaves, the lobes of whose bottom leaves are spear-shaped and sawed, and the upper ones linear and wing-pointed. Tragofelinum Austriacum maximum, foliis profundissime incis. Boerh. Hort. Chelf. Cat. 100. Largest Burnet Saxifrage of Austria, whose leaves are deeply cut.
6. **PIMPINELLA (Peregrina)** foliis radicalibus pinnatis crenatis, summis cuneiformibus incis. Lin. Sp. Plant. 164. Burnet Saxifrage, whose lower leaves are winged and indented on their edges, and the upper ones wedge-shaped and cut. Apium peregrinum foliis subrotundis. C. B. P. 153. Foreign Parsley with roundish leaves.
7. **PIMPINELLA (Anisum)** foliis radicalibus trifidis incis. Lin. Sp. Plant. 264. Pimpinell with trifid cut lower leaves. Anisum vulgare. Clus. Hist. 2. p. 202. Common Anise.

The first sort grows naturally in woods, and on the side of banks near hedges in several parts of England, especially upon chalky land. The lower leaves of this sort are wing-shaped, composed of three pair of heart-shaped lobes, and terminated by an odd one; they are sharply sawed on their edges, and sit close to the midrib. The lower lobes which are the largest, are near two inches long, and one and a half broad at their base, and are of a dark green. The stalks are more than a foot high, dividing into four or five branching foot-stalks; the lower part of the stalk is garnished with winged leaves, shaped like those at the bottom, but smaller; those upon the branches are short and trifid; the branches are terminated by

small umbels of white flowers, which are composed of smaller umbels or rays. The flowers have five heart-shaped petals which turn inward, and are succeeded by two narrow, oblong, channelled seeds. It flowers in July, and the seeds ripen in autumn. There is a variety of this with red flowers, which is frequently found among the other, and rises from the same seed. The second sort grows naturally in dry pastures in many parts of England; the lower leaves of this are composed of four pair of lobes, terminated by an odd one; these are roundish; those on the lower part of the leaf are about half an inch long, and the same breadth; they are indented on their edges; the stalks rise near a foot high, sending out three or four slender branches, which are garnished with very narrow leaves. The umbels of flowers are smaller than those of the first, as are also the flowers and seeds. It flowers about the same time.

The third sort grows naturally in dry gravelly pastures in several parts of England; the lower leaves of this sort have five or six pair of lobes terminated by an odd one, which are deeply cut almost to their midrib in form of wings. The stalks are slender, and rise about a foot high, sending out a few small branches, which have a narrow trifid leaf placed at each joint, and are terminated by small umbels of white flowers, composed of several rays standing upon pretty long foot-stalks. The flowers are small, and appear at the same time with the former.

The seeds of the fourth sort were sent me from Paris by Dr. Bernard de Jussieu. The lower leaves of this sort are composed of six or seven pair of lobes terminated by an odd one; these are heart-shaped, almost two inches long, and one and a half broad near their base; they are hairy, and of a pale green. The stalk rises near two feet high, dividing into several branches, which have one narrow five-pointed leaf at each joint, and are terminated with umbels of white flowers like those of the first sort.

The seeds of the fifth sort I gathered in Dr. Boerhaave's private garden near Leyden; the synonyme applied to it was the title he gave me for it, and he told me he had received the seeds of it from Austria. The lower leaves have five pair of lobes terminated by an odd one; these are placed at a wider distance from each other than those of the other sorts; they are near two inches long, and three quarters of an inch broad in the middle, drawing to a point at each end, and are deeply cut in regular jags opposite, in form of a winged leaf; they are of a lucid green, and have long foot-stalks. The stalks rise two feet high, dividing at the top into two or three slender branches, garnished at each joint with one wing-pointed narrow leaf. The umbels of flowers are very like the first.

All these sorts have perennial roots; they are propagated by seeds, which, if sown in the autumn, will more certainly succeed than when they are sown in the spring. When the plants come up, they will require no other culture but to thin them when they are too close, and keep them clean from weeds; the second year they will flower and produce ripe seeds, and the roots will abide some years, and continue to produce flowers and seeds, if they grow in poor land.

The first sort is directed for medicinal use, but the herbwomen either bring the third sort to market for it, or what is worse, substitute Burnet and Meadow Saxifrage in its stead. It enters the pulvis ari compositis, and is esteemed good for the gravel.

The last sort is the common Anise: this is an annual plant, which grows naturally in Egypt, but is cultivated in Malta and Spain, from which countries the seeds are annually brought to England. From these seeds there is a distilled water, and an oil drawn for medicinal use. The pastry-cooks also make great use of these seeds in several of their compositions, to give them an aromatic taste and smell. The lower leaves are divided into three lobes, which are deeply cut on their edges; the stalk rises a foot and a half high, dividing into several slender branches, which are garnished with narrow leaves, cut into three or four nar-

row segments, and are terminated by pretty large loose umbels, composed of many smaller umbels or rays, which stand upon pretty long foot-stalks. The flowers are small, and of a yellowish white; the seeds are oblong and swelling. It flowers in July, and if the season proves warm, the seeds will ripen in autumn. The seeds of this should be sown the beginning of April upon a warm border, where the plants are to remain; when they come up, they should be thinned, and kept clean from weeds, which is all the culture this plant requires, but is too tender to be cultivated in England for profit.

PINASTER. See PINUS.

PINGUICULA, Butterwort.

This plant is found growing upon bogs in many parts of England, but is never cultivated in gardens, so I shall pass it over with barely mentioning it.

PINUS. Tourn. Inst. R. H. 585. tab. 355. Raii Meth. Plant. 138. Lin. Gen. Plant. 956. The Pine-tree; in French, *Pin*.

The CHARACTERS are,

The male flowers are collected in a scaly conical bunch; they have no petals, but many stamens, which are connected at their base, but divide at the top, terminated by erect summits; these are included in the scales, which supply the want of petals and empalement. The female flowers are collected in a common oval cone, and stand at a distance from the male on the same tree. Under each scale of the cone is produced two flowers, which have no petals, but a small germen supporting an awl-shaped style, crowned by a single stigma. The germen afterward becomes an oblong oval nut, crowned with a wing, included in the rigid scale of the cone.

This genus of plants is ranged in the ninth section of Linnæus's twenty-fourth class, which includes the plants with male and female flowers on the same plant, whose stamens are joined in one body; to this genus he adds the *Larix* and *Abies* of Tournefort.

The SPECIES are,

1. **PINUS** (*Sylvestris*) foliis geminis primordialibus solitariis glabris. Hort. Cliff. 450. Pine-tree with two leaves in each sheath, but the first leaves are single. *Pinus sylvestris*. C. B. P. 491. The wild Pine, or Pineaster.
2. **PINUS** (*Pinea*) foliis geminis primordialibus solitariis ciliatis. Pine-tree with two gray leaves coming out of each sheath, and the first leaves single. *Pinus sativa*. C. B. P. 490. The cultivated Pine-tree, commonly called the Stone Pine.
3. **PINUS** (*Rubra*) foliis geminis brevioribus glaucis, conis parvis mucronatis. Pine-tree with two shorter gray leaves proceeding out of each sheath, and small acute-pointed cones. *Pinus sylvestris* foliis brevibus glaucis, conis parvis albis. Raii Syn. 2. 288. Wild Pine with shorter gray leaves, and small whitish cones, called Scotch Fir or Pine.
4. **PINUS** (*Tartarica*) foliis geminis brevioribus latiusculis glaucis, conis minimis. Pine-tree with two shorter broad leaves in each sheath which are gray, and the smallest cones, commonly called Tartarian Pine.
5. **PINUS** (*Montana*) foliis sæpius ternis tenuioribus viridibus, conis pyramidalis, squamis obtusis. Pine with three narrow green leaves often in each sheath, and pyramidal cones with blunt scales. *Pinus sylvestris montana altera*. C. B. P. 421. Another wild Mountain Pine, called Mugbo.
6. **PINUS** (*Cembro*) foliis quinis lævibus. H. Scan. 32. Lin. Sp. Plant. 1000. Pine-tree with five smooth leaves in each sheath. *Pinus sylvestris montana tertia*. C. B. P. 491. The third wild Mountain Pine, called Cembro.
7. **PINUS** (*Maritima*) foliis geminis longioribus glabris, conis longioribus tenuioribusque. Pine-tree with two longer smooth leaves in each sheath, and longer narrower cones. *Pinus maritima secunda*. Tabern. Icon. 937. The second maritime Pine.
8. **PINUS** (*Halepensis*) foliis geminis tenuissimis, conis obtusis, ramis patulis. Tab. 208. Pine-tree with two narrow leaves in each sheath, obtuse cones, and spreading branches. *Pinus Halepensis*, foliis tenuibus læte viridibus. Rand. Hort. Chelf. Cat. 158. Aleppo Pine with very narrow dark green leaves.

9. **PINUS** (*Virginiana*) foliis geminis brevioribus, conis vis, squamis acutis. Pine-tree with two shorter leaves in each sheath, and small cones with acute scales. *Pinus Virginiana* foliis binis brevioribus & crassioribus setis, minori cono singulis squamarum capitibus aculeo donatis. Pluk. Alin. 297. Virginian Pine with two shorter and thicker leaves in each sheath, and a smaller cone with each scale ending in a prickle, commonly called Jersey Pine.
10. **PINUS** (*Rigida*) foliis ternis, conis longioribus squamis rigidioribus. Pine-tree with three leaves, and longer cones having rigid scales, commonly called three-leaved Virginian Pine.
11. **PINUS** (*Teda*) foliis longioribus tenuioribus ternis, conis maximis laxis. Pine-tree with three longer narrower leaves, and the largest loose cones. *Pinus Virginiana tenuifolia tripilis*, i.e. ternis plerumque ex uno foliculo setis strobilis majoribus Pluk. Alm. 297. Virginian Pine-tree with three narrow leaves in each sheath, and larger cones, called the Frankincense-tree.
12. **PINUS** (*Echinata*) *Virginiana prælongis* foliis tenuioribus, cono echinato gracili. Pluk. Alm. 297. Virginian Pine with longer and narrower leaves, and a slender prickly cone, called three-leaved Bastard Pine.
13. **PINUS** (*Strobus*) foliis quinis scabris. Lin. Sp. Plant. 1001. Pine-tree with five rough leaves in each sheath, commonly called Lord Weymouth's Pine.
14. **PINUS** (*Palustris*) foliis ternis longissimis. Pine-tree with the longest leaves growing by threes out of each sheath. *Pinus Americana palustris trifolia*, foliis longissimis. Du Hamel. Three-leaved, Marsh, American Pine with the longest leaves.

There are some other species of this genus in America, which have not been sufficiently examined to ascertain their differences; and it is probable some of the European kinds, which are now supposed to be only varieties of the sorts here enumerated, may be distinct species; but as I have had no opportunities of seeing them, so I have omitted them here.

The first sort here enumerated is the Pineaster, or wild Pine, which grows naturally in the mountains in Italy and the south of France, where there are forests of these trees, which, if suffered to stand, grow to a large size; but in Switzerland they are frequently cut into shingles for covering their houses, and also for making pitch; and in the south of France, the young trees are cut for stakes to support their Vines. This grows to a large size; the branches extend on every side to a considerable distance, and while the trees are young, they are fully garnished with leaves, especially where they are not so close as to exclude the air from those within; but as they advance in age, the branches appear naked, and all those which are situated below become unsightly after years, for which reason they have not been much in esteem of late; for as the wood of the Scotch Fir is much preferable to this, and the branches being generally better garnished with leaves, so the latter has been more generally propagated than the former. The branches of this sort grow at a wider distance than those of the Scotch Pine, and are more horizontal; the leaves are much larger, thicker, and longer, and grow strait, have a broad surface on their inside, which has a furrow or channel running longitudinally; they are of a darker green, and their points are obtuse. The cones of this are seven or eight inches long, pyramidal, and have pointed scales; the seeds are oblong, a little flattened on their sides, and have narrow wings on their tops.

The second sort, which is generally called the Stone Pine, is very common in Italy; but I much doubt of the country where it grows naturally, for so far as I have been able to learn, there are none of these trees growing in any part of Italy, but where they have been planted, or where the seeds have scattered from planted trees; and I have frequently received the seeds of a Pine from China, which were taken out of the cones so like those of this sort, as not to be distinguished from them; but these have never grown, either by their being too old, or from their having been taken out of the cones; for if the seeds of Pines are kept in the cones, they will grow at ten or twelve years

years old; but when they are out of the cones, they seldom grow well after two years; and some sorts do not grow after one year. The leaves of this are not quite so long as those of the former sort, and are of a grayish or sea-green colour; the cones are not more than five inches long, but are very thick, roundish, and end in an obtuse point; the scales of the cones are flat, and the seeds are more than twice the size of those of the former. The kernels of these are frequently served up in deserts to the table during the winter season in Italy, and formerly they were used in medicine here, but of late years the Pistachia nuts have been generally substituted in lieu of them. The wood of this tree is white, not so full of resin as many of the other sorts, so is never cultivated for its wood, but chiefly for the beauty of its leaves and for the nuts, which are much esteemed in the south of France and in Italy. The third sort is generally known here by the title of Scotch Pine, from its growing naturally in the mountains of Scotland, but it is common in most parts of Europe; and Mons. du Hamel of the Royal Academy of Sciences at Paris, mentions his having received cones of this tree from St. Domingo in the West-Indies, so concludes that it grows indifferently in torrid, frozen, and temperate zones. It is by John Bauhin titled, *Pinus sylvestris Genevensis vulgaris*; so that it grows commonly in the mountains near that city, and all through Denmark, Norway, and Sweden. The wood of this tree is the red or yellow deal, which is the most durable of any of the kinds yet known; the leaves of this tree are much shorter than those of the former sorts, and are broader, of a grayish colour, and twisted, growing two out of each sheath; the cones are small, pyramidal, and end in narrow points; they are of a light colour, and the seeds are small.

This sort grows well upon almost every soil; I have planted numbers of the trees upon Peat-pits, where they have made great progress. I have also planted them in clay, where they have succeeded far beyond expectation; and upon sand, gravel, and chalk, they likewise thrive as well; but as they do not grow near so fast upon gravel and sand as upon moist ground, so the wood is much preferable; for those trees which have been cut down upon moist soils, where they have made the greatest progress, when they have been sawn out into boards, have not been valuable, the wood has been white and of a loose texture; whereas those which have grown upon dry gravelly ground, have proved nearly equal to the best foreign deals; and I doubt not but those plantations which of late years have been made of these trees, will, in the next age, not only turn greatly to the advantage of their possessors, but also become a national benefit; therefore this is the sort which I would recommend to be cultivated on barren lands.

The fourth sort grows naturally in Tartary, from whence I received the seeds. This hath a great resemblance to the Scotch Pine, but the leaves are broader, shorter, and their points are more obtuse; they emit a strong balsamic odour when bruised; the cones of this are very small, as are also the seeds, some of which were black, and others white; but whether they are from different trees or the same, I could not learn; for the seeds were taken out of the cones, but in the parcel there was not one entire cone.

The fifth sort grows naturally upon the mountains in Switzerland; this hath very narrow green leaves, which grow sometimes by pairs, and at others there are three coming out of each sheath; these generally stand erect; the cones are of a middle size and pyramidal; the scales are flat, having each a small obtuse rising, but are very compact, till they are opened by the warmth of the sun the second spring. The seeds of this are much less than those of the Pineaster, but larger than those of the Scotch Pine.

The sixth sort grows naturally in Switzerland, and is supposed to be the same as the Siberian, which I greatly doubt; for the cones of this are short and roundish, and the scales are close, whereas those of the Siberian Pine are long and looser; the leaves have

a near resemblance to each other, so far as I have observed in the specimens; but the plants which have been raised from the Switzerland seeds, have made much greater progress than those from the Siberian seeds, which can scarce be kept alive in England. The leaves are long and narrow, smooth to the touch, of a light green, and five of them come out from the same sheath; the branches are closely garnished with them; the cones are about three inches long, and the scales are pretty close; the seeds are pretty large, and their shells are easily broken.

The seventh sort grows in the maritime parts of Italy and the south of France; this hath long smooth leaves, growing by pairs in each sheath; the cones are very long and slender; the seeds are about the size of those of the Pineaster.

The eighth sort grows naturally near Aleppo, and in several other parts of Syria. This is a tree of middling growth in its native soil, and in England there are none of any large size, for most of the plants which were growing here before the year 1740, were killed by the frost that severe winter; the two largest which I have seen are growing at Goodwood in Sussex, the seat of his Grace the Duke of Richmond; these had been transplanted thither the year before, so had scarce recovered their removal, and had made no shoots that summer, therefore escaped much better than those plants which were in great vigour, most of which were destroyed. This tree branches out on every side near the root; the branches at first grow horizontally, but turn their ends upward; their bark is smooth, and of a dark gray colour. The leaves are long and very narrow, of a dark green, and grow by pairs in each sheath; if they are bruised, they emit a strong resinous odour. The cones come out from the side of the branches; they are not much more than half the length of those of the Pineaster, but are full as large at their base; the scales are flattened, and the point of the cone obtuse. The seeds are much less than those of the Pineaster, but of the same shape.

The ninth sort grows naturally in most parts of North America; this never rises to any great height, and is the least esteemed in the country of all the sorts. While the plants are young, they make a pretty good appearance; but when they get to the height of seven or eight feet, they become ragged and unsightly, so are not worth cultivating.

The tenth sort grows naturally in Virginia, and other parts of North America, where it rises to a great height; and so far as we can judge by the growth of those trees which are now here, it seems likely to become a large tree in England. There are many of them now growing in the noble plantation of evergreen trees in his Grace the Duke of Bedford's park at Wooburn, which are twenty feet high, though not of many years standing, and keep pace with the other kinds of Pines and Firs in the same plantation. The leaves of this are long, three generally standing in each sheath; the cones of this sort come out in clusters round the branches; they are as long as the cones of the Pineaster, and have rigid scales; the seeds are winged, and nearly as large as those of the Pineaster. The eleventh sort grows naturally in North America; this hath very long narrow leaves, growing by threes out of each sheath; the cones are as large as those of the Stone Pine, but the scales are looser, and the cones more pointed. The scales of this open horizontally, and discharge the seeds. This sort was sent over from America to Mr. Ball of Exeter, and also to Dr. Compton Bishop of London, by the title of *Frankincense Pine*.

The twelfth sort grows naturally in Virginia; the cones of this have been brought to England of late years, by the title of *Bastard three-leaved Pine*. The leaves of this sort are long and narrow; sometimes there are three growing in each sheath, and at others but two; the cones are long, slender, and their scales terminate in sharp points; they are rather longer than those of the Pineaster, and not so thick.

The

The thirteenth sort grows naturally in most parts of North America, where it is called the white Pine. It is one of the tallest trees of all the species, often growing a hundred feet high in those countries, as I have been credibly informed; the bark of this tree is very smooth and delicate, especially when young; the leaves are long and slender, five growing out of each sheath; the branches are pretty closely garnished with them, so make a fine appearance; the cones are long, slender, and very loose, opening with the first warmth of the spring, so that if they are not gathered in winter, the scales open and let out the seeds. The wood of this sort is esteemed for making masts for ships; it is in England titled Lord Weymouth's, or New England Pine. As the wood of this tree was generally thought of great service to the navy, there was a law made in the ninth year of Queen Anne for the preservation of the trees, and to encourage their growth in America; and it is within forty years past these trees began to be propagated in England in any plenty, though there were some large trees of this sort growing in two or three places long before, particularly at Lord Weymouth's, and Sir Wyndham Knatchbull's in Kent; and it has been chiefly from the seeds of the latter, that the much greater number of these trees now in England have been raised; for although there has annually been some of the seeds brought from America, yet these have been few in comparison to the produce of the trees in Kent; and many of the trees which have been raised from the seeds of those trees, now produce plenty of good seeds, particularly those in the gardens of his late Grace the Duke of Argyle at Whitton, which annually produce large quantities of cones, which his Grace did most generously distribute to all the curious.

This sort and the Scotch Pine, are the best worth cultivating of all the kinds for the sake of their wood; the others may be planted for variety in parks; &c. where they make a good appearance in winter, when other trees are destitute of leaves.

All the sorts of Pines are propagated by seeds, which are produced in hard woody cones; the way to get out their seeds is to lay the cones before a gentle fire, which will cause the cells to open, and then the seeds may be easily taken out. If the cones are kept entire, the seeds will remain good for some years; so that the surest way to preserve them, is to let them remain in the cones until the time for sowing the seeds; if the cones are kept in a warm place in summer, they will open, and emit the seeds; but if they are not exposed to much heat, they will remain entire some years, especially those which are close and compact; and the seeds which have been taken out of Cones of seven years old, have grown very well, so that these may be transported to any distance, provided the cones are well ripened and properly put up.

The best time for sowing the seeds of Pines is about the end of March, and when the seeds are sown, the place should be covered with nets to keep off birds, otherwise, when the plants begin to appear with the husk of the seed on their tops, the birds will pick off the heads of the plants and destroy them.

Where the quantity of seeds to be sown is not great, it will be a good way to sow them either in boxes or pots, filled with light loamy earth, which may be removed from one situation to another, according to the season of the year; but if there is a large quantity of the seeds, so as to require a good space to receive them, they should be sown on an East or North-east border, where they may be screened from the sun, whose heat is very injurious to these plants at their first appearance above ground. Those seeds which are sown in pots or boxes, should also be placed in a shady situation, but not under trees; and if they are screened from the sun with mats at the time when the plants first come up, it will be a good method to preserve them.

Most of the sorts will come up in about six or seven weeks after they are sown, but the seeds of the Stone or cultivated Pine, and two or three of the others,

whose shells are very hard, frequently lie in the ground a whole year; so that when the plants do not come up the first year, the ground should not be disturbed, but kept clean from weeds, and the following spring the plants will rise. This frequently happens in dry seasons, and when they are sown in places a little too much exposed to the sun. Therefore the surest method is, to soak the seeds in water twenty-four hours before they are sown.

When the plants appear, they must be constantly kept clean from weeds; and in very dry seasons, if they are now and then gently refreshed with water, it will forward their growth; but this must be done with great care and caution, for if they are hastily watered, it will wash the tender plants out of the ground, or lay them down flat, which often rots their shanks; and when this is too often repeated, it will have the same effect; so that unless it is judiciously performed, it will be the best way to give them none, but only screen them from the sun.

If the plants come up too close, it will be a good method to thin them gently about the beginning of July. The plants which are drawn up may then be planted on other beds which should be prepared ready to receive them, for they should be immediately planted as they are drawn up, because their tender roots are soon dried and spoiled at this season of the year. This work should be done (if possible) in cloudy or rainy weather, and then the plants will draw out with better roots, and will soon put out new fibres again; but if the weather should prove clear and dry, the plants should be shaded every day from the sun with mats, and now and then gently refreshed with water. In drawing up the plants, there should be great care taken not to disturb the roots of the plants left remaining in the seed-beds, &c. so that if the ground be hard, the beds should be well watered some time before the plants are thinned, to soften and loosen the earth; and if after the plants are drawn out, the beds are again gently watered to settle the earth to the roots of the remaining plants, it will be of great service to them, but it must be done with great care, so as not to wash out their roots, or lay down the plants. The distance which should be allowed these plants in the new beds, is four or five inches row from row, and three inches in the rows.

In these beds the plants may remain till the spring twelve months after, by which time they will be fit to transplant where they are to remain for good, for the younger the plants are when planted out, the better they will succeed; for although some sorts will bear transplanting at a much greater age, yet young plants planted at the same time will in a few years overtake the large ones, and soon outstrip them in their growth; and there is an advantage in planting young, by saving the expence of staking, and much watering, which large plants require. I have several times seen plantations of several sorts of Pines, which were made of plants six or seven feet high, and at the same time others of one foot high planted between them, which in ten years were better trees than the old ones, and much more vigorous in their growth; but if the ground where they are designed to remain cannot be prepared by the time before-mentioned, the plants should be planted out of the beds into a nursery, where they may remain two years, but not longer; for it will be very hazardous removing these trees at a greater age.

The best season to transplant all the sorts of Pines is about the latter end of March or the beginning of April, just before they begin to shoot; for although the Scotch Pine, and some of the most hardy sorts, may be transplanted in winter, especially when they are growing in strong land, where they may be taken with balls of earth to their roots; yet this is what I would not advise for common practice, having frequently seen it attended with bad consequences; but those which are removed in the spring rarely fail.

Where these trees are planted in exposed situations, they should be put pretty close together, that they may

P I N

shelter each other ; and when they have grown a few years, part of the plants may be cut down to give room for the others to grow ; but this must be gradually performed, lest by too much opening the plantation at once, the air should be let in among the remaining trees with too great violence, which will stop their growth.

Although these Evergreen-trees are by many persons despised on account of their dark green in summer, yet a proper mixture of these in large clumps make a fine appearance about a seat in winter, and in summer, by their contrast with other trees, have no bad effect in diversifying the scene.

Wherever large plantations are designed to be made, the best method will be to raise the plants either upon a part of the same land, or as near to the place as possible, and also upon the same sort of soil : a small piece of ground will be sufficient to raise plants enough for many acres, but, as the plants require some care in their first raising, if the neighbouring cottagers, who have many of them small inclosures adjoining to their cottages, or where this is wanting, a small inclosure should be made them for the purpose of raising the plants, and they are furnished with the seeds and directions for sowing them, and managing the young plants till they are fit for transplanting, the women and children may be usefully employed in this work ; and the proprietors of land agreeing with them to take their plants when raised at a certain price, it would be a great benefit to the poor ; and hereby they would be engaged to have a regard for the plantations when made, and prevent their being destroyed. The Scotch Pine, as was before observed, being the hardiest of all the kinds, and the wood of it the most useful, is the sort which best deserves care. This will thrive upon the most barren sands, where scarce any thing else except Heath and Furze will grow ; so that there are many thousand acres of such land lying convenient for water carriage, which at present is of little benefit to any body, that might, by plantations of these trees, become good estates to their proprietors, and also a national benefit ; and as the legislature have taken this into their consideration, and already passed some laws for the encouraging these plantations, as also for their preservation and security, so it may be hoped that this will be undertaken by the gentlemen who are possessed of such lands in all the different parts of the kingdom with proper spirit ; for although they may not expect to receive much profit from these plantations in their own time, yet their successors may with large interest ; and the pleasure which these growing trees will afford them, by beautifying the present dreary parts of the country, will in some measure recompense them for their trouble and expence ; and by creating employment for the poor, lessen those rates which are now so high in many parts of England as scarce to be borne.

The expence of making these plantations is what most people are afraid of, so would not engage in it ; but the greatest of the expence is that of fencing them from the cattle, &c. for the other is trifling, as there will be no necessity for preparing the ground to receive the plants ; and the charge of planting an acre of land with these plants will not be more than twenty or thirty shillings where labour is dear, exclusive of the plants, which may be valued at forty shillings more. I have planted many acres of land with these trees, which was covered with Heath and Furze, and have only dug holes between to put in the plants, and afterward laid the Heath or Furze which was cut, upon the surface of the ground about their roots, to prevent the ground drying, and few of the plants have failed. These plants were most of them four years old from seed, nor was there any care taken to clean the ground afterward, but the whole left to shift, and in five or six years the Pines have grown so well as to overpower the Heath and Furze, and destroy it.

The distance which I have generally planted these plants in all large open situations was about four feet, but always irregular, avoiding planting in rows as

P I N

much as possible ; and in the planting, the great care is not to take up the plants faster than they can be planted, so that some men have been employed in digging up the plants while others were planting. Those who take up the plants must be looked after, to see they do not tear off their roots or wound their bark ; and as fast as they are taken up, their roots should be covered to prevent their drying, and put into their new quarters as soon as possible. In planting them, care should be had to make the holes large enough for their roots, as also to loosen and break the clods of earth, and put the finest immediately about their roots, then to settle the earth gently with the foot to the roots of the plant. If these things are duly observed, and a proper season chosen for performing it, there will be very little hazard of their succeeding ; but I have seen some plantations made with plants which were brought from a great distance, and had been so closely packed up as to cause a heat, whereby most of the plants within had their leaves changed yellow, and few of them have grown, which has discouraged others from planting, not knowing the true cause of their failure.

After the plantations are made, the only care they require for five or six years will be to secure the plants from cattle, hares, and rabbits ; for if these are admitted to them, they will make great destruction in a short time ; for if the branches are gnawed by hares or rabbits, it will greatly retard the growth of the plants, if not destroy them.

In about five or six years after planting, the branches of the young trees will have met, and begin to interfere with each other ; therefore they will require a little pruning, but this must be done with great caution. The lower tier of branches only should be cut off ; this should be performed in September, at which time there will be no danger of the wounds bleeding too much, and the turpentine will harden over the wounds as the season grows cold, so will prevent the wet from penetrating the wounds. These branches should be cut off close to the stem of the plants, and care should be taken in doing this not to break any of the remaining branches of the young trees. This work should be repeated every other year, at each time taking off only the lower tier of branches ; for if the plants are much trimmed, it will greatly retard their growth, as it does in general that of all trees ; but as these trees never put out any new shoots where they are pruned, so they suffer more from amputation than those which do.

In those parts of France where they have forests of these trees, the proprietors always give the faggots to those, who prune their young trees first, for their labour, so it costs them no money. At the second pruning the proprietor has one-third of the faggots, and the dressers have the other two for their work, and afterward the faggots are equally divided between the workmen and proprietors, but there must be great care taken that they do not cut off more than should be.

In about twelve or fourteen years these will require no more pruning, for their upper branches will kill those below where they have not air ; but soon after this, if the plants have made good progress, it may be necessary to thin them ; but this should be gradually performed, beginning in the middle of the plantation first, leaving the outside close to screen those within from the cold, so by degrees coming to them at last, whereby those which were first thinned will have had time to get strength, so will not be in danger of suffering from the admission of cold air. When these plantations are thinned, the trees should not be dug up, but their stems cut off close to the ground, for their roots never shoot again, but decay in the earth, so there can no harm arise by leaving them, and hereby the roots of the remaining plants are not injured. The trees which are now cut will be fit for many purposes ; those which are strait will make good putlocks for the bricklayers, and serve for scaffolding poles, so that there may be as much made by the sale

sale

sale of these, as will defray the whole expence of the planting, and probably interest for the money into the bargain.

As the upright growth of these trees renders their wood the more valuable, they should be left pretty close together, whereby they will draw each other up, and grow very tall. I have seen some of these trees growing, whose naked stems have been more than seventy feet high, and as straight as a walking-cane, and from one of these trees there were as many boards sawed, as laid the floor of a room near twenty feet square. If these trees are left eight feet asunder each way, it will be sufficient room for their growth; therefore if at the first thinning a fourth part of the trees are taken away, the other may stand twelve or fourteen years longer, by which time they will be of a size for making ladders and standards for scaffolding, and many other purposes; so that from this sale as much may be made, as not only to pay the remaining part of the expence of planting, if any should be wanting in the first, but rent for the land with interest, and the standing trees for the fortunes of younger children. This may be demonstrated by figures, and there has been several examples of late years, where the profits have greatly exceeded what is here mentioned.

The fifth sort is called in Switzerland Torch Pine; the peasants there make use of the wood of this tree instead of torches for burning. This tree grows to a great height in its native soil, and is well furnished with branches. The wood is pretty full of resin, and when first cut is of a reddish colour; this is used by the inhabitants in their buildings.

The sixth sort of Pine makes but slow progress in England, unless upon the summits of the northern mountains, where upon the peaty moors, this and the Siberian Pine are likely to succeed much better than in any other part of Britain, for they naturally grow among snow.

The eighth sort is never a large tree in its native country, and in England it grows more like a shrub than a tree, and is often greatly injured by cold in winter, and by severe frosts sometimes killed, so that this is only kept for the sake of variety in the English gardens.

The ninth and tenth sorts are used indifferently by the inhabitants of North America for their buildings, and the same purposes as the other sorts of Pine.

There are some varieties of these in America, if they are not distinct species. Some of them ripen their cones the first year, but others are two years, and some three before they are ripe; but as these have not been well distinguished by those who reside in that country, and there are few of the sorts so large in England as to produce cones, so their differences can not as yet be ascertained.

The eleventh and twelfth sorts I believe are indifferently called red Pine in North America, where their wood is greatly esteemed; the French at Canada have built a sixty-gun ship entirely of this wood, called the Saint Laurent. I have had had a little of this wood from America, which was very like that of the Scotch Pine, but had rather more resin. It may not be amiss to make trial of some of these sorts in plantations, to see which of them may deserve to be propagated; for in some places where they are growing they thrive very well, but these will not succeed so well on dry land as on moist.

The thirteenth sort is called the white Pine in most parts of North America; of this I believe there are two varieties, if not distinct species; but as they have not been well examined by persons of skill, we cannot take upon us to determine this, for Monsieur Gaultier's description of one species is very different from that of the Weymouth Pine, and yet he has applied the title of white Pine to both.

This sort deserves to be propagated for its beauty, which is superior to all the sorts of Pines yet known in England. The bark of the young trees and the branches are perfectly smooth; the branches are well

garnished with leaves, which are long, and of an agreeable green, so that in summer they have a beauty, and in winter they make a better appearance than any of the sorts. The wood of this tree is very useful, especially for masts of ships, as the trees grow very tall and straight, and are pliable, so do not break with the wind, therefore the legislature thought proper to pass a law for the preservation and increase of these trees in America; but as these trees will thrive in England, they may be propagated in many places where the soil is proper for them. This sort grows best upon a moist light soil, but it should not be too wet; it will also thrive on a loamy soil, if it is not too much approaching to clay. The seeds of this sort should be sown with a little more care than those of the Scotch Pine, because their stems are not so strong, therefore are more apt to go off while young; so if these are sown in the full ground, the bed should be screened with mats from the sun every day, but exposed to the dews every night. When the plants come up, they should be treated in the same way as is before directed for the Scotch Pine; and if all the plants of this kind are transplanted into beds in July, it will be a secure way to preserve them; but as these plants will grow faster than those of the Scotch Pine, they should be planted farther asunder; their rows should be six inches distant, and in the rows they should be four inches apart. This will allow them room to grow till the spring twelvemonth following, when they may be either transplanted where they are to remain, or into a nursery, where they may stand two years to get strength; but the sooner they are planted where they are to stand, the less danger there will be of their succeeding, and the larger they will grow; for although they will bear transplanting at a greater age, yet when they are planted young, they will make much greater progress, and grow to a greater size.

The soil in which this sort of tree thrives best is a soft hazel loam, not too wet, in which I have frequently measured shoots of one year, which were two feet and a half long, and have for some years continued growing so much: they should have a sheltered situation, for I have observed where the trees have been much exposed to the South-west winds, they have not made near so great a progress as those which grew in shelter; and where there have been plantations of these trees, those on the outside have not kept pace with the middle, nor have their leaves retained their verdure so well.

The fourteenth sort grows naturally on swamps in many parts of North America, where I have been informed they grow to the height of twenty-five or thirty feet. Their leaves are a foot or more in length, growing in tufts at the end of the branches, so have a singular appearance, but I have not heard the wood was of any use but for fuel; and there are few places here where these plants do well, for in very severe frosts their leading shoots are often killed, and in dry ground they will not thrive; so that unless the soil is adapted for them, it is to little purpose planting them.

From the wild Pine or Pineaster is procured the common turpentine, which is chiefly used by the farriers, and from it is distilled the oil of turpentine. The finer and more valuable part, which comes first, is called the spirit, what is left at the bottom of the still is the common resin.

The kernels of the nuts of the manured or Stone Pine are of a balsamic nourishing nature, good for consumptions, coughs, and hoarseness, restorative, and of service after long illness.

PIPER. Lin. Gen. Plant. 42. Saururus. Plum. Nov. Gen. 51. tab. 12. Pepper, or Lizard's-tail.

The CHARACTERS are,

The flowers are closely fastened to a single stalk, and have no complete sheath; these have no petals nor stamens, but have two summits opposite to the root of the germen, which are roundish; they have a large oval germen, but no style, crowned by a prickly triple stigma. The germen afterward

afterward becomes a roundish berry with one cell, containing one globular seed.

This genus of plants is ranged in the third section of Linnæus's second class, which includes those plants whose flowers have two male, and three female parts of generation.

The SPECIES are,

1. PIPER (*Obtusifolium*) foliis obovatis enerviis. Lin. Sp. Plant. 30. *Pepper with obverse oval leaves having no veins.* Saururus humilis, folio carnosio, subrotundo. Plum. Cat. 51. *Low Lizard's-tail with a fleshy roundish leaf.*
2. PIPER (*Pelucidum*) foliis cordatis petiolatis, caule herbaceo. Lin. Sp. Plant. 30. *Pepper with heart-shaped leaves having foot-stalks, and an herbaceous stalk.* Piper foliis cordatis, caule procumbente. Hort. Cliff. 6. tab. 4. *Pepper with heart-shaped leaves and a trailing stalk.*
3. PIPER (*Amalago*) folis lanceolato-ovatis quinquenerviis rugosis. Lin. Sp. Plant. 29. *Pepper with rough, oval, spear-shaped leaves having five veins.* Saururus foliis lanceolato-ovatis quinquenerviis rugosis. Hort. Cliff. 140. *Lizard's-tail with rough, spear-shaped, oval leaves, having five veins.*
4. PIPER (*Humilis*) foliis lanceolatis nervosis rigidis sessilibus. *Pepper with stiff, spear-shaped, veined leaves sitting close to the branches.* Piper longum humilium, fructu à summitate caulis prodeunte. Sloan. Cat. Jam. 45. *Dwarf long Pepper, with the fruit coming out at the end of the stalk.*
5. PIPER (*Peltatum*) foliis peltatis orbiculato-cordatis obtusis repandis, spicis umbellatis. Lin. Sp. Plant. 30. *Pepper with target-formed leaves which are orbicular, heart-shaped, obtuse, recurved, and have spikes growing in umbels.* Saururus arborescens, foliis amplis, rotundis & umbilicatis. Plum. Cat. 51. *Tree Lizard's-tail with large, round, navel-shaped leaves.*
6. PIPER (*Laurifolia*) foliis lanceolato-ovatis nervosis, spicis brevibus. *Pepper with spear-shaped, oval, veined leaves, and short spikes.* Saururus frutescens, lauro-cerasi folio, fructu brevior & crassior. Hoult. MSS. *Shrubby Lizard's-tail with a Laurel leaf, and a shorter thicker fruit.*
7. PIPER (*Tomentosum*) foliis ovato-lanceolatis tomentosis, caule arborescente. *Pepper with oval, spear-shaped, woolly leaves, and a tree-like stalk.* Saururus arborescens latifolia, villosa fructu gracili. Hoult. MSS. *Broad-leaved, tree-like, hairy Lizard's-tail, with a slender fruit.*
8. PIPER (*Aduncum*) foliis ovato-lanceolatis, nervis alternis, spicis uncinatis. Lin. Sp. Plant. 29. *Pepper with oval spear-shaped leaves, having alternate veins and crooked spikes.* Saururus arborescens fructu adunco. Plum. Cat. 51. *Lizard's-tail with a crooked fruit.*
9. PIPER (*Decumanum*) foliis cordato-ovatis nervosis acuminatis, spicis reflexis. *Pepper with oval, heart-shaped, nerved, acute-pointed leaves, and reflexed spikes.* Saururus frutescens plantaginis folio ampliore, fructu brevior & gracilior adunco. Hoult. MSS. *Shrubby Lizard's-tail with a larger Plantain leaf, and a shorter and slenderer crooked spike.*
10. PIPER (*Siriboa*) foliis cordatis subseptinerviis venosis. Flor. Zeyl. 29. *Pepper with heart-shaped leaves which are veined, and have almost seven nerves.*
11. PIPER (*Reticulatum*) foliis cordatis septemnerviis reticulatis. Lin. Sp. Plant. 29. *Pepper with heart-shaped netted leaves having seven veins.* Saururus botryoides major, foliis plantaginis. Plum. Cat. 51. *Greater Lizard's-tail with Plantain leaves.*
12. PIPER (*Glabrum*) foliis ovato-lanceolatis acuminatis glabris trinerviis. *Pepper with oval, spear-shaped, acute-pointed, smooth leaves, having three veins.* Saururus racemosus, seu botryides minor. Plum. Cat. 51. *Small branching, or clustered Lizard's-tail.*
13. PIPER (*Racemosum*) foliis lanceolato-ovatis rugosis, nervis alternis. *Pepper with spear-shaped, oval, rough leaves, having alternate veins.* Saururus racemosus, seu botryites major. Plum. Cat. 51. *Greater branching, or clustered Lizard's-tail.*

The first sort grows naturally in many of the islands in the West Indies. This sends out from the root

many succulent herbaceous stalks almost as large as a man's little finger; they are jointed, and divide into many branches, never rising above a foot high, but generally spread near the ground, putting out roots at each joint, so propagate very fast, and soon cover a large space of ground. The leaves are very thick and succulent; they are about three inches long and two broad, very smooth and entire. The foot-stalk, which sustains the spike or tail, comes out at the end of the branches; this is also very succulent, and the whole length, including the spike, is about seven inches. The spike is strait, erect, and about the size of a goose-quill, closely covered with small flowers which require a glass to be distinguished, so have no beauty; but the whole spike much resembles the tail of a lizard, for which Plumier gave it that title.

These spikes appear great part of the year, but they rarely have any seeds in England; the plants increase very fast by their stalks, which put out roots. It requires a warm stove to preserve it in England, and should have but little wet, especially in winter. If the plants are plunged into the tan-bed in the stove, the stalks will put out roots into the tan, so may be cut off to make new plants.

The second sort grows naturally in the West-Indies; this is annual. The stalks are herbaceous and succulent; they rise about seven or eight inches high; the leaves are heart-shaped, an inch and a half long, and three quarters of an inch broad; the spikes of flowers come out at the end of the stalks; they are slender, about an inch long, and strait; the flowers are very small, and sit close to the foot-stalk. These appear in July, and are succeeded by very small berries, each containing a small seed like dust. If these seeds are permitted to scatter on the pots near it, the plants will come up without trouble; or if the seeds are saved, and sown upon a hot-bed in the spring, the plants will rise easily. These should be transplanted into separate pots, and plunged into a hot-bed of tanners bark, treating them in the same way as other tender plants, but they should not have much wet.

The third sort grows naturally in Jamaica and Barbadoes. This hath several crooked stems, which rise to the height of twelve or fourteen feet, which are jointed, hollow, and pithy; these divide into many small branches, which are garnished with spear-shaped oval leaves about three inches and a half long, and one and a half broad; they are rough, and have five longitudinal veins. The spikes come out at the end of the branches; they are slender, and about three inches long; these have many small flowers sitting close to the foot-stalk, which are succeeded by small berries.

The fourth sort grows naturally in Jamaica. The stalks of this are slender, and frequently trail upon the ground, putting roots out from their joints like the first; they are garnished with stiff spear-shaped leaves five inches long, and two broad in the middle, drawing to a point at each end; they have one strong midrib, and on the backside have several veins running from that to the sides. The spike of flowers is very slender, and about five inches long, shaped like those of the former sorts.

The fifth sort grows naturally in Jamaica; this hath a pretty thick spongy stalk which rises fifteen feet high, dividing into several branches which are jointed, and pithy; the leaves are almost round; the foot-stalk is fastened to the under side, so that the upper surface has a mark like a navel where the stalk joins, and from that center run out the veins to the side. The leaves are about a foot diameter; their lower part is indented like a heart, but the other part is round, and the stalk being fixed toward the middle, the leaves have the appearance of a target. The spikes are small, and grow in form of an umbel.

The sixth sort grows naturally at La Vera Cruz in America. This hath shrubby jointed stalks which rise nine or ten feet high, dividing into smaller branches, which are garnished with spear-shaped oval leaves seven inches long, and three broad, ending in

in acute points; they are veined and rough, of the same consistence with Laurel leaves. The spikes of flowers come out from the side of the branch at the joints, opposite to the leaves; they are not more than one inch and a half long, about the thickness of a small quill, and are closely set with flowers like the other sorts.

The seventh sort was discovered by the late Dr. Houstoun growing naturally at La Vera Cruz. This hath hollow pithy stalks, which rise twelve or fourteen feet high, dividing into many crooked branches having swelling joints, which are garnished with oval spear-shaped leaves, about five inches long and three broad, having many veins, and are covered with a woolly down. The spikes of flowers come out from the side of the branches opposite to the leaves; they are slender, and about three inches long, turning downward.

The eighth sort grows naturally in Jamaica; this hath many hollow stalks, which rise about five feet high; the joints are pretty close and protuberant; these divide into smaller branches, which are garnished with oval spear-shaped leaves, seven inches long and three broad in the middle; they are rough and veined, the veins coming out alternately from the midrib, diverging to the sides, and join the borders of the leaf at the top. The spikes of flowers come out from the side of the branches, opposite to the leaves; they are slender, five inches long, and are incurved; these are closely set with small flowers their whole length. This is called Spanish Elder in the West-Indies.

The ninth sort was sent me from Carthagenia by the late Dr. William Houstoun; this rises with several shrubby stalks fifteen feet high, dividing into many slender branches with protuberant joints, which are garnished with heart-shaped oval leaves, five inches long and three broad, ending in acute points; they are smooth, and at their base have five veins, but the two outer join the borders of the leaves soon; the other three run to the top, the middle one in a right line; the two side veins diverge, and join together at the top; the leaves are of a dark green on their upper side, but pale on their under. The spikes of flowers come out from the side of the branches; they are extremely slender, an inch and a half long, and are reflexed at the end like a scorpion's tail.

The tenth sort was sent me by Mr. Robert Millar from Panama, near which place it grows naturally. This hath hollow shrubby stalks which rise about four feet high, and divide into many small branches, which are garnished with heart-shaped leaves about five inches long, and four broad near their base, ending in long acute points; these have seven veins at their base, but the two outer soon diverge to the borders of the leaves, and unite with them; the other five are extended almost to the length of the leaves, diverging from the midrib toward the sides, and unite toward the top. The spikes come out from the side of the branches; they are slender, and about four inches long, bending in the middle like a bow, and are closely set with small herbaceous flowers, which are succeeded by small berries, inclosing a small single seed.

The eleventh sort grows naturally in Jamaica; this rises with a shrubby pithy stalk about five feet high, sending out several side branches which have protuberant joints, and are garnished with heart-shaped leaves six inches long and five broad near their base. They have five veins which arise from the foot-stalk, the middle one going in a direct line to the point; the two side veins diverge toward the edges of the leaves in the middle, but approach again at the top; the surface of the leaves is full of small veins, which form a sort of net-work. The spikes come out from the side of the branches opposite to the leaves; they are slender, and about five inches long, a little bending in the middle, and are closely set with very small herbaceous flowers.

The twelfth sort grows naturally at Campeachy, from whence it was sent me by the late Dr. Houstoun.

This hath many shrubby stalks which rise about ten feet high, and divide into several crooked branches toward the top, which have swelling joints, and are garnished with oval spear-shaped leaves near four inches long, and two and a half broad, terminating in acute points; they are smooth, of a lucid green, and have three large veins running longitudinally; the middle or midrib being strait, the two outer diverging toward the sides in the middle of the leaf, but are drawn together again at the point. The spikes come out from the side of the stalks opposite to the leaves; they are pretty long, slender, and a little incurved. The flowers and seeds are like the other species.

The thirteenth sort grows naturally at Campeachy; this hath a shrubby stalk, which rises ten or twelve feet high, dividing toward the top into a great number of small branches, which are hollow, and have protuberant joints; they are garnished with spear-shaped, oval, rough leaves, about five inches long, and two inches and a half broad; some of them have long, and others very short foot-stalks; they are of a deep green on their upper side, but pale on their under, ending in acute points. The spikes come out from the side of the stalks, opposite to the leaves; they are long and slender, and are closely set with very small flowers like the other species.

The eleven last-mentioned sorts are abiding plants, which require a warm stove to preserve them in England. They may be propagated by seeds, if they can be procured fresh from the countries where the plants grow naturally; these should be sown upon a good hot-bed in the spring, and when the plants come up and are fit to transplant, they should be each put into a separate small pot filled with light fresh earth, and plunged into a hot-bed of tanners bark, shading them every day from the sun till they have taken fresh root; then they must be treated in the same way as other tender exotic plants, admitting fresh air to them daily in proportion to the warmth of the season, to prevent their drawing up weak; and when the nights are cold, the glasses of the hot-bed should be covered with mats to keep them warm. As the stalks of most of these plants are tender when young, so they should not have much wet, which would rot them; and when water is given to them it must be with caution, not to beat down the plants; for when that is done, they seldom rise again.

In autumn the plants must be plunged into the tan-bed of the bark-stove, and during the winter they must be sparingly watered; they require the same warmth as the Coffee-tree. In the summer they require a large share of fresh air in hot weather, but they must be constantly kept in the stove, for they are too tender to bear the inclemency of our weather in summer.

PISCIDIA. Lin. Gen. 856. Piscipula. Loefl. It. 275.

The CHARACTERS are,

The flower is of the butterfly kind; the empalement is of one leaf, indented in five parts; the standard is rising, and indented at the end; the wings are as long as the standard, the keel is moon-shaped and rising. It hath ten stamina covered with a sheath at bottom, which opens at the top; these are terminated by oblong summits: the germen is linear and compressed, supporting a narrow rising style crowned by a pointed stigma. This becomes a narrow pod, having four longitudinal borders with one cell, and between each isthmus have one cylindrical seed.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, intitled Diadelphia Decandria, the flowers having ten stamina in two bodies.

The SPECIES are,

1. PISCIDIA (*Erythrina*) foliolis ovatis. Jacq. Amer. 27. *Piscidia with oval leaves.* Coral arbor polyphylla, non spinosa, fraxini folio, siliquis alis foliaceis extantibus rotæ molendinaria fluvialis acuta. Sloan. Hist. 2. p. 39. *Dogwood-tree.*
2. PISCIDIA (*Carthaginensis*) foliolis obovatis. Jacq. Amer. 27. *Piscidia with oblong oval leaves.* Phaseolis accedens Coral arbor polyphyllus, foliis durioribus

non spinosa. Pluk. Alm. 293. tab. 214. f. 4. *Dog-wood-tree with oblong oval leaves.*

The first sort grows plentifully in Jamaica, where it rises with a stem to the height of twenty-five feet or more, which is almost as large as a man's body, covered with a light coloured smooth bark, and sending out several branches at the top without order; these are garnished with winged leaves, whose pinnæ or lobes are oval; there are generally seven in each leaf; these are about two inches long, and one and a half broad, placed for the most part opposite, and terminated by an odd lobe; the flowers are of the butterfly kind, of a dirty white colour, and are succeeded by oblong pods, which have four longitudinal wings, and are jointed between the cells which contain the seeds.

The negroes in the West-Indies make use of the bark of this tree to catch fish, which, if thrown into the water will intoxicate the fish, and cause them to rise to the surface of the water, and turn upon their backs, so are easily caught; but this intoxication is not of long continuance, nor has it been known to give any bad quality to the fish.

The second sort is also a native of the West-Indies; it differs from the first in the shape and consistence of the leaves, which are more oblong, and of a firmer texture than those of the first, but in other respects they are very similar.

Both sorts are easily propagated by seeds, when they can be obtained fresh from the countries where they naturally grow, for in Europe these plants do rarely flower; there are plants now in the Chelsea Garden which are more than twenty years old, and if they had not been two or three times shortened, would have been more than twenty-five feet high, yet have not attempted to flower though they are in perfect health. The seeds must be sown upon a good hot-bed in the spring, and when the plants come up and are fit to transplant, they should be each planted in a small pot filled with light earth, and plunged into a hot-bed of tanners bark, and afterward treated in the same way as hath been directed for the ERYTHRINA, to which article the reader is desired to turn, to avoid repetition.

PISONIA. Plum. Nov. Gen. 7. tab. 11. Lin. Gen. Plant. 984. Fingrigo, vulgò.

The CHARACTERS are,

The male flowers grow upon different plants from the fruit. The male flowers have a small erect empalement, cut into five acute points. The flowers are funnel-shaped, the tube is short; the brim is expanded, and cut into five acute parts; they have five awl-shaped stamina which are longer than the petal, terminated by obtuse summits. The female flowers have empalements like the male, and the flowers are of the same form; they sit upon the germen, which is situated under the receptacle, supporting a cylindrical style longer than the petal, crowned by five oblong spreading stigmas. The germen afterward turns to an oval capsule having five angles and one cell, containing one smooth, oblong, oval seed.

This genus of plants is ranged in the fifth section of Linnæus's twenty-second class, which includes those plants whose male and female flowers are upon different plants, and the female flowers have five stigmas or styles.

We have but one SPECIES at present in England, viz.

PISONIA (*Aculeata*) spinis axillaribus patentissimis. Lin. Sp. Plant. 1511. *Prickly Pisonia, called Fingrigo in the West-Indies.* Pisonia aculeata, fructu glutinoso & racemoso. Plum. Nov. Gen. 7. *Prickly Pisonia with a glutinous branching fruit.*

The title of this genus was given by Father Plumier, in honour of Dr. William Piso, who published a Natural History of Brasil. The name of Fingrigo is what the inhabitants of Jamaica know it by.

The male plants differ so much in appearance from the female, that those who have not seen them rise from the same seeds, would suppose they were

different species, I shall therefore give short descriptions of each.

The male plants have stalks as thick as a man's arm, which rise ten or twelve feet high; the bark is of a dark brown colour, and smooth; these send out many branches by pairs opposite, which are much stronger than those of the female, so do not hang about so loose. They are garnished with obverse, oval, stiff leaves, an inch and a half long, and an inch and a quarter broad, standing opposite on short foot-stalks. From the side of the branches come out short cursons or spurs, like those of the Pear-tree, having each two pair of small leaves at bottom, and from the top comes out the foot-stalk of the flowers which is slender, about half an inch long, dividing at the top into three; each of these sustain a small corymbus of herbaceous yellow flowers, each having five stamina standing out beyond the petal, terminated by obtuse summits.

The stalks of the female plants are not so strong as those of the male, so require support. These rise eighteen or twenty feet high, sending out slender weak branches opposite, which are armed with short, strong, hooked spines, and garnished with small oval leaves, about an inch and three quarters broad; these stand opposite on the larger branches, but on the smaller they are alternate, and have short foot-stalks. The flowers are produced in small bunches at the end of the branches, sitting upon the germen; they are shaped like those of the male, but have no stamina; in the center is situated a cylindrical style, crowned by five spreading stigmas. The germen afterward turns to a channelled, five-cornered, glutinous capsule, armed with small crooked spines, each containing one oblong, oval, smooth seed.

These plants are very common in the savannas, and other low places in the island of Jamaica, as also in several other islands in the West-Indies, where it is very troublesome to whoever passes through the places of their growth, fastening themselves by their strong crooked thorns to the clothes of the persons; and their seeds being glutinous and burry, also fasten themselves to whatever touches them; so that the wings of the ground-doves and other birds, are often so loaded with the seeds, as to prevent their flying, by which means they become an easy prey.

In Europe this plant is preserved in the gardens of some curious persons for variety; it is propagated by seeds, which should be sown in pots filled with light rich earth, and plunged into a hot-bed of tanners bark; and when the plants come up, they should be transplanted into separate pots, and plunged into the hot-bed again, where they may remain till Michaelmas, when they should be removed into the stove, and plunged into the bark-bed, and treated in the same manner as hath been directed for several tender plants of the same country; observing in hot weather to give them plenty of water, but in winter they should have it more sparingly. They are too tender to thrive in the open air of this country at any season of the year, wherefore they should be constantly kept in the stove. They retain their leaves most part of the year in England.

PISTACIA. Lin. Gen. Plant. 982. Terebinthus. Tourn. Inst. R. H. 579. tab. 345. Lentiscus. Tourn. Inst. R. H. 580. Turpentine-tree, Pistachia-nut, and Mastick-tree.

The CHARACTERS are,

The male and female flowers grow upon separate trees; the male flowers are disposed in loose sparsed catkins, having small scales with one flower; these have small five-pointed empalements, but no petals; they have five small stamina, terminated by oval, four-cornered, erect summits. The female flowers have small trifid empalements, but no petals; they have each a large oval germen, supporting three reflexed styles, crowned by thick prickly stigmas. The germen afterward turns to a dry berry or nut, inclosing an oval smooth seed.

This genus of plants is ranged in the third section of Linnæus's twenty-second class, which includes those plants

plants which have male and female flowers on separate plants, whose female flowers have three styles.

The SPECIES are,

1. PISTACIA (*Terebinthus*) foliis impari pinnatis, foliolis subovato recurvis. Lin. Mat. Med. 454. Sp. Plant. 145. *Pistachia with unequal winged leaves, whose lobes are somewhat oval and recurved.* Terebinthus Indica Theophrasti pistacia Dioscoridis. Adv. 413. *The Pistachia-tree.*
2. PISTACIA (*Trifolia*) foliis subternatis. Hort. Cliff. 456. *Pistachia with trifoliate leaves.* Terebinthus, seu pistacia trifolia. Tourn. Inst. 580. *Three-leaved Turpentine, or Pistachia-tree.*
3. PISTACIA (*Narbonensis*) foliis pinnatis ternatisque, suborbiculatis. Lin. Sp. Plant. 1025. *Pistachia with winged and trifoliate leaves, which are almost round.* Terebinthus peregrina, fructu majore, pistaciis simili, eduli. C. B. P. 400. Tourn. Inst. 579. *Foreign Turpentine-tree, with a large eatable fruit like Pistachia.*
4. PISTACIA (*Vera*) foliis impari pinnatis, foliolis ovato-lanceolatis. Hort. Cliff. 456. *Pistachia with unequal winged leaves, whose lobes are oval and spear-shaped.* Terebinthus vulgaris. C. B. P. 400. *The common Turpentine-tree.*
5. PISTACIA (*Lentiscus*) foliis abruptè pinnatis, foliolis lanceolatis. Hort. Cliff. 456. *Pistachia with abrupt winged leaves, and narrow spear-shaped lobes.* Lentiscus vulgaris. C. B. P. 399. *Common Mastick-tree.*
6. PISTACIA (*Maffiliensis*) foliis abruptè pinnatis, foliolis lineari lanceolatis. *Pistachia with abrupt winged leaves, and narrow spear-shaped lobes.* Lentiscus angustifolia Maffiliensis. H. R. Par. *Narrow-leaved Mastick-tree of Marseilles.*
7. PISTACIA (*Americana*) foliis impari pinnatis, foliolis lanceolato-ovatis acuminatis. *Pistachia with unequal winged leaves, whose lobes are spear-shaped, oval, and acute-pointed.* Terebinthus pistaciæ fructu non eduli. Plum. Cat. 17. *Turpentine-tree with a fruit like the Pistachia, which is not eatable.*
8. PISTACIA (*Simaruba*) foliis pinnatis deciduis, foliolis oblongo ovatis. *Pistachia with winged deciduous leaves, having oblong oval lobes.* Terebinthus major, betulæ cortice, fructu triangulari. Sloan. Hist. Jam. 2. p. 89. tab. 199. *Greater Turpentine-tree with a bark like the Birch-tree, and a triangular fruit, commonly called Birch-tree in Jamaica.*

The first sort is the Pistachia-nut-tree, whose fruit is much better known in England than the tree. This grows naturally in Arabia, Persia, and Syria, from whence the nuts are generally brought to Europe. In those countries it grows to the height of twenty-five or thirty feet; the bark of the stem and old branches are of a dark russet colour, but that of the young branches is of a light brown; these are garnished with winged leaves, composed sometimes of two, and at others of three pair of lobes, terminated by an odd one; these lobes approach toward an oval shape, and their edges turn backward; if these are bruised, they emit an odour like the shell of the nut. Some of these trees produce male flowers, others have female, and some, when old, have both on the same tree. The male flowers come out from the side of the branches, in loose bunches or catkins; they are of an herbaceous colour, having no petals, but have each five small stamina, crowned by large four-cornered summits filled with farina; when that is discharged, the flowers fall off. The female flowers come out upon different trees in clusters from the side of the branches; these have no petals, but have each a large oval germen, supporting three reflexed styles; these are succeeded by oval nuts. This tree flowers in April, but the fruit never ripens in England. It is propagated by the nuts, which should be planted in pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed to bring up the plants; when these appear, they should have a large share of air admitted to them, to prevent their drawing up weak; and by degrees they must be hardened to bear the open air, to which they should be exposed the beginning of June, and may remain abroad till autumn,

when they should be placed under a hot-bed frame to screen them from the frost in winter; for while they are young, they are too tender to live through the winter in England without protection, but they should always be exposed to the air in mild weather; these plants shed their leaves in autumn, so should not have much wet in winter; and in the spring, before the plants begin to shoot, they must be transplanted each into a separate small pot; and if they are plunged into a very moderate hot-bed, it will forward their putting out new roots; but as soon as they begin to shoot, they must be gradually hardened, and placed abroad again; these plants may be kept in pots three or four years till they have got strength, during which time they should be sheltered in winter; and afterward they may be turned out of the pots, and planted in the full ground, some against high walls to a warm aspect, and others in a sheltered situation, where they will bear the cold of our ordinary winters very well, but in severe frosts they are often destroyed. The trees flower and produce fruit in England, but the summers are not warm enough to ripen the nuts.

The second sort grows naturally in Sicily and the Levant, where it is a tree of a middling size, covered with a rough brown bark, and dividing into many branches, which are garnished with leaves, which for the most part have three, but some have four oval lobes; they stand upon long foot-stalks, and are of a dark green colour. The male flowers grow upon different trees from the female, and are like those of the former sort, but are of a yellowish green colour. The female flowers of this sort I have not seen, so can give no account of them; these are succeeded by fruit like that of the former, but are much smaller. This is propagated by seeds in the same manner as the former, and the plants should be treated in the same way, but require more protection in winter. There were several plants of this kind in the English gardens before the year 1740, which had lived abroad some years against walls, but that severe winter killed most of them.

The third sort grows in Italy and the South of France, but is supposed to have been transplanted there from some other country. This is a tree of a middling size, covered with a light gray bark, sending out many side branches, which are garnished with leaves which have sometimes five, and at others but three roundish lobes, which stand upon pretty long foot-stalks, and are of a light green colour. The male flowers grow upon separate trees from the fruit, as in the other sorts; the fruit of this is small, but eatable. This is propagated by nuts in the same way as the first, and the plants are equally hardy.

The fourth sort grows naturally in Barbary, and also in Spain, Italy, and the Levant. This is a tree of middling size, covered with a brown bark, and dividing into many branches, whose bark is very smooth while young, garnished with winged leaves, composed of three or four pair of oval spear-shaped lobes, terminated by an odd one. The flowers are male and female on different trees, as the former: the male flowers of this have purplish stamina; they appear in April, but I have not seen any of the female trees in flower. This is propagated by seeds, but unless they are sown in autumn soon after they are ripe, they seldom grow the first year, but remain in the ground a whole year; and unless the seeds are taken from such trees as grow near the male, the seeds will not grow, as I have several times experienced.

The plants of this sort may be treated in the same manner as the first, and are as hardy. There is a tree of this sort now growing in the gardens of the Bishop of London at Fulham, against a wall, which was planted there above fifty years ago, and has endured the winters without cover; and some trees of this kind which were planted in the open air, in the garden of his Grace the Duke of Richmond at Goodwood in Suffex, had survived several winters without any protection. From these trees the common turpentine

pentine of the shops was formerly taken, but there is little of that now imported, but that from some of the cone-bearing trees is generally substituted for it. The fifth sort is the common Mastick-tree, which is better known in the gardens by its Latin title of *Lentiscus*. This grows naturally in Spain, Portugal, and Italy, and being evergreen, the plants have been preserved in the English gardens to adorn the greenhouse in winter. This in its native countries rises to the height of eighteen or twenty feet, covered with a gray bark, sending out many branches, which have a reddish brown bark, and are garnished with winged leaves, composed of three or four pair of small spear-shaped lobes, without an odd one at the end. The midrib which sustains the lobes, has two narrow borders or wings, running from lobe to lobe; these lobes are of a lucid green on their upper side, but pale on their under. The male flowers come out in loose clusters from the sides of the branches; they are of an herbaceous colour, appearing in May, and soon fall off. These are generally upon different plants from the fruit, which also grows in clusters, and are small berries, of a black colour when ripe.

The plants of this sort are generally propagated by laying down of their young branches, which, if properly managed, will put out roots in one year, and may then be cut off from the old plants, and each transplanted into separate small pots. These must be sheltered in winter, and in summer placed abroad in a sheltered situation, and treated in the same way as other hardy kinds of greenhouse plants. It may also be propagated by seeds in the same way as the Turpentine-tree; but if the seeds are not taken from trees growing in the neighbourhood of the male, they will not grow; and if they are kept out of the ground till spring, the plants rarely appear till the spring following. When these plants have obtained strength, some of them may be turned out of the pots, and planted against warm walls; where, if their branches are trained against the walls, they will endure the ordinary winters very well, and with a little shelter in severe winters they may be preserved.

The sixth sort grows naturally about Marseilles, and in some other places in the South of France, where it rises to the same height as the former from which it differs, in having one or two pair of lobes more on each leaf, and the lobes are much narrower, and of a paler colour. This difference holds in the plants which are propagated by seeds, so may be pronounced a distinct species. It is propagated in the same way as the former sort, and is equally hardy.

The seventh sort grows naturally in many of the islands in the West-Indies, where it rises to a middling stature, dividing into many branches, which are covered with a purplish bark, and garnished with winged leaves, composed of two or three pair of spear-shaped, oval, acute-pointed lobes, terminated by an odd one; these are an inch and three quarters long, and near an inch broad, running out in acute points; they are very thin and tender, and have long foot-stalks. The male flowers come out at the end of the branches; they are disposed in a single racemus (or long bunch) about three inches long; they are of a purplish colour, and have yellow summits. The fruit grows upon separate trees from the male flowers; they are shaped like the nuts of *Pistachia*, but are smaller and not eatable. This was sent me by Dr. Cressy from Antigua.

The eighth sort grows naturally in Jamaica, and also in most of the other islands in the West-Indies, where it rises to the height of thirty or forty feet, covered with a loose brown bark, which falls off in large pieces; the stems are large, and divide into many branches toward the top, which are crooked and unsightly; these are garnished with winged leaves, composed of five or six pair of oblong, oval, smooth lobes, about four inches long and two broad, terminated by an odd one. The flowers come out at the end of the branches, in long loose bunches of a yellowish colour; these grow on different trees, or on different parts of the same tree from the fruit, which also hangs in long bunches,

and is about the size of a middling Pea, having a dark skin covering a nut about the size of a common Cherry-stone, and of the same colour.

These two trees are tender, so will not thrive in this country, unless they are kept in a warm stove. They are propagated by seeds, which must be taken from such trees as grow in the neighbourhood of the males, otherwise they will not grow, as I have too often found true. These should be sown in pots filled with light earth, and plunged into a good hot-bed of tanners bark; and when the plants are come up fit to remove, they should be each planted in a separate small pot, and plunged into a fresh hot-bed, treating them in the same way as the other tender plants from the same countries, and in the autumn they should be removed into the stove, plunging the pots into the tan-bed; and during the winter they must have but little water, especially if they cast their leaves, which is generally the case after the first winter; for the young plants generally retain their leaves the whole year, but afterward they are destitute of leaves for two months, in the latter part of the winter. These plants should constantly remain in the stove, but in warm weather they must have a large share of air admitted to them.

PISUM. Tourn. Inst. R. H. 394. tab. 215. Lin. Gen. Plant. 779. [Some are of opinion, that this plant takes its name from the city Pisa, where it anciently grew in plenty; others derive it from *πίσιον*, which comes from *πίσσω*, to fall; because, if this plant be not supported, it will fall to the ground.] Pea; in French, *Pois*.

The CHARACTERS are,
The flower hath a one-leaved permanent empalement cut into five points, the two upper being broadest; it hath four petals, and is of the butterfly kind. The standard is broad, heart-shaped, reflexed, and indented, ending in a point. The two wings are shorter, roundish, and close together; the keel is compressed, moon-shaped, and shorter than the wings. It hath ten stamina in two bodies, the upper single one is plain and awl-shaped, the other nine are cylindrical below the middle, awl-shaped above and cut; these are joined together, and are terminated by roundish summits. It has an oblong compressed germen, with a triangular rising style, crowned by a hairy oblong stigma. The germen afterward becomes a large, long, taper pod, terminated by a sharp rising point, opening with two valves, having one row of roundish seeds.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which contains those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. **PISUM (Sativum)** stipulis infernè rotundatis crenatis, petiolis teretibus, pedunculis multifloris. Hort. Upsal. 215. Pea whose lower stipulæ are roundish and indented, with taper foot-stalks bearing many flowers. *Pisum hortense majus*, flore fructuque albo. C. B. P. 342. Greater Garden Pea with a white flower and fruit.
2. **PISUM (Humile)** caule erecto ramoso, foliis bijugatis, foliolis rotundioribus. Pea with an erect branching stalk, and leaves having two pair of round lobes. *Pisum humile*, caule firmo. Tourn. Inst. R. H. 394. Dwarf Pea with a firm stalk.
3. **PISUM (Umbellatum)** stipulis quadrifidis acutis, pedunculis multifloris terminalibus. Pea with four-pointed acute stipulæ, and foot-stalks bearing many flowers, which terminate the stalks. *Pisum umbellatum*. C. B. P. 342. The Rose or Crown Pea.
4. **PISUM (Maritimum)** petiolis suprà planiusculis, caule angulato, stipulis sagittatis, pedunculis multifloris. Flor. Succ. 608. Pea with foot-stalks which are plain on their upper side, an angular stalk, arrow-pointed stipulæ, and foot-stalks bearing many flowers.
5. **PISUM (Americanum)** caule angulato procumbente, foliolis inferioribus lanceolatis acutè dentatis, summis sagittatis. Pea with an angular trailing stalk, whose lower leaves are spear-shaped and sharply indented, and those at the top arrow-pointed, commonly called Cape Horn Pea.

6. *Pisum (Ochrus) petiolis decurrentibus-membranaceis diphyllis, pedunculis unifloris.* Hort. Cliff. 379. *Pea with membranaceous running foot-stalks; having two leaves and one flower upon a foot-stalk.* Ochrus folio integro capreolos emittente. C. B. P. 343. *Winged Pea with an entire leaf sending out tendrils.*

There are a great variety of Garden Peas now cultivated in England, which are distinguished by the gardeners and seedsmen, and have their different titles; but as great part of these are only feminal variations, and if not very carefully managed, by taking away all those plants which have a tendency to alter before the seeds are formed, they will degenerate into their original state, so that all those persons who are curious in the choice of their seeds, look carefully over those which they design for seeds at the time when they begin to flower, and draw out all the plants which they dislike from the other. This is what they call roguing their Peas, meaning hereby, the taking out all the bad plants from the good, that the farina of the former may not impregnate the latter; to prevent which, they always do it before the flowers are fully open; by thus diligently drawing out the bad, and marking those which come earliest to flower, they have greatly improved their Peas of late years, and are constantly endeavouring to get forwarder varieties; so that it would be to little purpose in this place, to attempt giving particular botanical titles to each which are now cultivated; therefore I shall only mention their titles by which they are commonly known, placing them according to their time of coming to the table, or gathering for use.

The Golden Hotspur.	Sugar Dwarf.
The Charlton.	Sickle Pea.
The Reading Hotspur.	Marrowfat.
Masters's Hotspur.	Dwarf Marrowfat.
Essex Hotspur.	Rose, or Crown Pea.
The Dwarf Pea.	Rouncival Pea.
The Sugar Pea.	Gray Pea.
Spanish Morotto.	Pig Pea, with some others.
Nonpareil.	

The English Sea Pea is found wild upon the shore in Sussex, and several other counties in England. This was first taken notice of in the year 1555, between Orford and Aldborough, where it grew upon the heath, where nothing, no not Grass, was ever seen to grow; and the poor people being in distress, by reason of the dearth of that year, gathered large quantities of these Peas, and so preserved themselves and families. This is mentioned by Stowe in his Chronicle, and Camden in his Britannia: but they were both mistaken, in imagining that they were Peas cast on shore by a shipwreck, seeing they grow in divers other parts of England, and are undoubtedly a different species from the common Pea.

The fifth sort hath a perennial root, which continues some years. This was brought from Cape Horn by Lord Anson's cook, when he passed that Cape, where these Peas were a great relief to the sailors. It is kept here as a curiosity, but the Peas are not so good for eating as the worst sort now cultivated in England; it is a low trailing plant; the leaves have two lobes on each foot-stalk, those below are spear-shaped, and sharply indented on their edges, but the upper leaves are small and arrow-pointed. The flowers are blue, each foot-stalk sustaining four or five flowers; the pods are taper, near three inches long, and the seeds are round, about the size of Tares.

The sixth sort is annual; this grows naturally amongst the Corn in Sicily and some parts of Italy, but is here preserved in botanic gardens for the sake of variety. It hath an angular stalk rising near three feet high; the leaves stand upon winged foot-stalks, each sustaining two oblong lobes. The flowers are of a pale yellow colour, and shaped like those of the other sorts of Pea, but are small, each foot-stalk sustaining one flower; these are succeeded by pods about two inches long, containing five or six roundish seeds, which are a little compressed on their sides. These are by some persons eaten green, but unless they are gathered very young, they are coarse, and at

best not so good as the common Pea. It may be sown and managed in the same way as the Garden Pea. I shall now proceed to set down the method of cultivating the several sorts of Garden Peas, so as to continue them throughout the season.

It is a common practice with the gardeners near London, to raise Peas upon hot-beds, to have them very early in the spring; in order to which, they sow their Peas upon warm borders under walls or hedges, about the middle of October; and when the plants come up, they draw the earth up gently to their stems with a hoe, the better to protect them from frost. In these places they let them remain till the latter end of January, or the beginning of February, if they are preserved from frosts, observing to earth them up from time to time as the plants advance in height (for the reasons before laid down) as also to cover them in very hard frost with Peas-haulm, straw, or some other light covering, to preserve them from being destroyed; then, at the time before-mentioned, they make a hot-bed (in proportion to the quantity of Peas intended) which must be made of good hot dung, well prepared and properly mixed together, that the heat may not be too great. The dung should be laid about three feet thick, or somewhat more, according as the beds are made earlier or later in the season; when the dung is equally levelled, then the earth (which should be light and fresh, but not over rich) must be laid on about six or eight inches thick, laying it equally all over the bed. This being done, the frames (which should be two or two and a half feet high on the back side, and about eighteen inches in front) must be put on, and covered with glasses; after which it should remain three or four days, to let the steam of the bed pass off, before you put the plants therein, observing every day to raise the glasses to give vent for the rising steam to pass off; then when you find the bed of a moderate temperature for heat, you should, with a trowel, or some other instrument, take up the plants as carefully as possible, to preserve the earth to the roots, and plant them into the hot-bed in rows about two feet asunder; and the plants should be set about an inch distant from each other in the rows, observing to water and shade them until they have taken root; after which you must be careful to give them air at all times when the season is favourable, otherwise they will draw up very weak, and be subject to grow mouldy and decay. You should also draw the earth up to the shanks of the plants as they advance in height, and keep them always clear from weeds. The water they should have must be given them sparingly, for if they are too much watered it will cause them to grow too rank, and sometimes rot off the plants at their shanks just above ground. When the weather is very hot, you should cover the glasses with mats in the heat of the day, to screen them from the violence of the sun, which is then too great for them, causing their leaves to flag, and their blossoms to fall off without producing pods, as will also the keeping the glasses too close at that season. But when the plants begin to fruit, they should be watered oftener, and in greater plenty than before; for by that time the plants will have nearly done growing, and the often refreshing them will occasion their producing a greater plenty of fruit.

The sort of Pea which is generally used for this purpose is the Dwarf, for all the other sorts ramble too much to be kept in frames; the reason for sowing them in the common ground, and afterwards transplanting them on a hot-bed, is also to check their growth, and cause them to bear in less compass; for if the seeds were sown upon a hot-bed, and the plants continued thereon, they would produce such luxuriant plants as are not to be contained in the frames, and would bear but little fruit.

The next sort of Pea which is sown to succeed those on the hot-bed is the Hotspur, of which there are reckoned three or four sorts; as the Golden Hotspur, the Charlton Hotspur, the Masters's Hotspur, the Reading Hotspur, and some others, which are very little differing from each other, except in their early

bearing, for which the Golden and Charlton Hot-spurs are chiefly preferred; though if either of these sorts are cultivated in the same place for three or four years, they are apt to degenerate and be later in spring-fruited, for which reason most curious persons procure their seeds annually from some distant place; and in the choice of these seeds, if they could be obtained from a colder situation and a poorer soil, than that in which they are to be sown, it will be much better than on the contrary, and they will come earlier in the spring. These must also be sown on warm borders, towards the latter end of October; and when the plants are come up, you should draw the earth up to their shanks in the manner before directed; which should be repeated as the plants advance in height (always observing to do it when the ground is dry) which will greatly protect the stems of the plants against frost; and if the winter should prove very severe, it will be of great service to the plants to cover them with Peas-haulm, or some other light covering; which should be constantly taken off in mild weather, and only suffered to remain on during the continuance of the frost; for if they are kept too close, they will be drawn very weak and tender, and thereby be liable to be destroyed with the least inclemency of the season.

In the spring you must carefully clear them from weeds, and draw some fresh earth up to their stems; but do not raise it too high to the plants, lest by burying their leaves you should rot their stems, as is sometimes the case, especially in wet seasons. You should also observe to keep them clear from vermin, which, if permitted to remain amongst the plants, will increase so plentifully as to devour the greatest part of them. The chief of the vermin which infest Peas are the slugs, which lie all the day in the small hollows of the earth, near the stems of the plants, and in the night time come out, and make terrible destruction of the Peas; and these chiefly abound in wet soils, or where a garden is neglected, and over-run with weeds; therefore you should make the ground clear every way round the Peas to destroy their harbours, and afterwards in a fine mild morning very early, when these vermin are got abroad from their holes, you should slack a quantity of lime, which should be sown hot over the ground pretty thick, which will destroy the vermin wherever it happens to fall upon them, but will do very little injury to the Peas, provided it be not scattered too thick upon them. This is the best method I could ever find to destroy these troublesome vermin.

If this crop of Peas succeeds, it will immediately follow those on the hot-bed; but for fear this should miscarry, it will be proper to sow two more crops at about a fortnight's distance from each other, so that there may be the more chances to succeed. This will be sufficient until the spring of the year, when you may sow three more crops of these Peas; one toward the beginning of January, the other a fortnight after, and the third at the end of January. These two late sowings will be sufficient to continue the early sort of Peas through the first season, and after this it will be proper to have some of the large sort of Peas to succeed them for the use of the family; in order to which, you should sow some of the Spanish Morotto, which is a great bearer, and a hardy sort of Pea, about the middle of February, upon a clear open spot of ground. These must be sown in rows about three feet asunder, and the Peas should be dropped in the drills about an inch distance, covering them about two inches deep with earth, being very careful that none of them lie uncovered, which will draw the mice, pigeons, or rooks, to attack the whole spot; and it often happens by this neglect, that a whole plantation is devoured by these creatures; whereas, when there are none of the Peas left in sight, they do not so easily find them out.

About a fortnight after this you should sow another spot, either of this sort, or any other large sort of Pea, to succeed those, and then continue to repeat sowing once a fortnight, till the middle or latter end of May, some of these kinds, only observing to allow

the Marrowfats, and other very large sorts of Peas, at least three feet and a half, or four feet between row and row; and the Rose Pea should be allowed at least eight or ten inches distance plant from plant in the rows, for these grow very large; and if they have not room allowed them, they will spoil each other by drawing up very tall, and will produce no fruit.

When these plants come up, the earth should be drawn up to their shanks (as was before directed) and the ground kept entirely clear from weeds; and when the plants are grown eight or ten inches high, you should stick some rough boughs, or brushwood, into the ground close to the Peas, for them to ramp upon, which will support them from trailing upon the ground, which is very apt to rot the large-growing sorts of Peas, especially in wet seasons; besides, by thus supporting them, the air can freely pass between them, which will preserve the blossoms from falling off before their time, and occasion them to bear much better than if permitted to lie upon the ground, and there will be room to pass between the rows to gather the Peas when they are ripe.

The dwarf sorts of Peas may be sown much closer together than those before-mentioned, for these seldom rise above a foot high, and rarely spread above half a foot in width, so that these need not have more room than two feet row from row, and not above an inch asunder in the rows. These produce a good quantity of Peas, provided the season is not over-dry, but they seldom continue long in bearing, so that they are not so proper to sow for the main crop, when a quantity of Peas is expected for the table, their chief excellency being for hot-beds, where they will produce a greater quantity of Peas (provided they are well managed) than if exposed to the open air, where the heat of the sun soon dries them up.

The Sickle Pea is much more common in Holland than in England, it being the sort mostly cultivated in that country; but in England they are only propagated by curious gentlemen for their own table, and are rarely brought into the markets. This sort the birds are very fond of, and if they are not prevented, many times destroy the whole crop. This should be planted in rows about two feet and a half asunder, and should be managed as hath been directed for the other sorts. Although I have directed the sowing of the large sorts of Peas for the great crop, yet these are not so sweet as the early Hotspur Peas; therefore it will also be proper to continue a succession of those sorts through the season, in small quantities, to supply the best table, which may be done by sowing some every week or ten days; but all those which are sown late in the season, should have a strong moist soil, for in hot light land they will burn up and come to nothing.

The large-growing sorts may be cultivated for the common use of the family, because these will produce in greater quantities than the other, and will endure the drought better, but the early kinds are by far the sweeter tasted Peas.

The best of all the large kinds is the Marrowfat, which if gathered young, is a well-tasted Pea, and this will continue good through the month of August if planted on a strong soil.

The gray and other large winter Peas are seldom cultivated in gardens, because they require a great deal of room, but are usually sown in fields in most parts of England. The best time for sowing these is about the beginning of March, when the weather is pretty dry, for if they are put into the ground in a very wet season, they are apt to rot, especially if the ground be cold; these should be allowed at least three or four feet distance row from row, and must be sown very thin in the rows; for if they are sown too thick, the haulm will spread so as to fill the ground, and ramble over each other, which will cause the plants to rot, and prevent their bearing.

The common white Pea will do best on light sandy land, or on a rich loose soil. The usual method of sowing these Peas is with a broad cast, and so harrow them in; but it is a much better way to sow them in drills

drills about three feet asunder, for less than half the quantity of seed will do for an acre, and being set regularly, the ground may be stirred with a hoe to destroy the weeds, and earth up the Peas, which will greatly improve them, and the Peas may be much easier cut in autumn, when they are ripe. The usual time for sowing these Peas is about the middle of March, or the beginning of April, on warm land, but on cold ground they should be sown a fortnight or three weeks later. In the common way of sowing, they allow three bushels or more to an acre; but if they are drilled, one bushel and a half will be full enough.

The Green and Maple Rouncivals require a stronger soil than the White, and should be sown a little later in the spring; also the drills should be made at a greater distance from each other, for as these are apt to grow rank, especially in a wet season, they should be set in rows two feet and a half or three feet asunder; and the ground between the rows should be stirred two or three times with a hoe, which will not only destroy the weeds, but, by earthing up the Peas, will greatly improve them, and also render the ground better to receive whatever crop is put on it the following season.

The gray Peas thrive best on a strong clayey land; these are commonly sown under furrow, but by this method they are always too thick, and do not come up regular; therefore all these rank-growing plants should be sown in drills, where the seeds will be more equally scattered, and lodged at the same depth in the ground; whereas in the common way some of the seeds lie twice as deep as others, and are not scattered at equal distances. These may be sown toward the end of February, as they are much hardier than either of the former sorts, but the culture for these should be the same.

The best method to sow these Peas is to draw a drill with a hoe by a line about two inches deep, and then scatter the seeds therein; after which, with a rake, you may draw the earth over them, whereby they will be equally covered, and this is a very quick method for gardens; but where they are sown in fields, they commonly make a shallow furrow with the plough, and scatter the seeds therein, and then with a harrow they cover them over again. After this, the great trouble is to keep them clear from weeds, and draw the earth up to the plants; this, in such countries where labour is dear, is a great expence to do it by the hand with a hoe; but this may be easily effected with a horse-hough, which may be drawn through between the rows, which will entirely eradicate the weeds, and by stirring the soil render it mellow, and greatly promote the growth of the plants.

When any of the best sorts are intended for seed, there should be as many rows of them left ungathered, as may be thought necessary to furnish a sufficient quantity of seed; and when the Peas are in flower, they should be carefully looked over, to draw out all those plants which are not of the right sort; for there will always be some roguish plants (as the gardeners term them) in every sort, which, if left to mix, will degenerate the kind. These must remain until their pods are changed brown and begin to split, when you should immediately gather them up, together with the haulm; and if you have not room to stack them till winter, you may thresh them out as soon as they are dry, and put them up in sacks for use; but you must be very careful not to let them remain too long abroad after they are ripe, for if wet should happen it would rot them; and heat, after a shower of rain, would cause their pods to burst, and cast forth their seeds, so that the greatest part of them would be lost; but, as I have said before, it is not advisable to continue sowing of the same seed longer than two years on the same ground, for the reasons there laid down, but rather to exchange their seeds every year, or every two years at least, whereby you may always expect to have them prove right.

PISUM CORDATUM. See CARDIOSPERMUM.
PITTONIA. See TOURNEFORTIA.

PLANT A, a Plant, is defined by the ingenious Mr. John Martyn to be an organical body, destitute of sense and spontaneous motion, adhering to another body in such a manner, as to draw from it its nourishment, and having power of propagating itself by seed. As to the parts of which a plant consists, they are the root, stalk, leaf, flower, and fruit.

Plant and Vegetable are pretty near terms synonymous, all plants being vegetables. Dr. Boerhaave defines a vegetable to be a body generated of the earth, or something arising of the earth, to which it adheres, or is connected by parts called roots, through which it receives the matter of its nourishment and increase, and consists of juices and vessels sensibly distinct from each other; or a vegetable is an organical body, composed of vessels and juices, every where distinguishable from each other; to which body grow roots or parts, whereto it adheres, and from which it derives the matter of its life and growth.

This definition furnishes a just and adequate idea of a vegetable; for by its consisting of vessels and juices, it is distinguished from a fossil; and by its adhering to another body, and deriving its nourishment therefrom, it is distinguished from an animal.

A vegetable is defined an organical body, because consisting of different parts, which jointly concur to the exercise of the same functions, adhering by some of its parts to another body; for we know of no plant that is absolutely vague and fluctuating, but has still a body it adheres to, though that body may be various, e. g. Earth, as in our common plants; stone, as in rock plants; water, as in sea plants; and air, as some mucilages.

As to those few plants which appear to float in the water, their manner of growth is something anomalous. Monsieur Tournefort has shewn that all plants do not arise strictly from seeds, but that some, instead of semen, deposit or let fall a little drop of juice, which, sinking in the water, reaches the bottom, or some rock, &c. in its way, to which it sticks, strikes root, and shoots into branches; such is the origin of coral. Add, that the root of a plant may have any situation at pleasure, with respect to the body thereof, nor needs it either be lowest or highest, &c. Accordingly in Aloes, Mistleto, Coral, Mosses, Funguses, &c. the root is frequently uppermost, and its growth downwards.

The vessels or containing parts of plants consist of mere earth, bound or connected together by oil, as a gluten, which being exhausted by fire, air, age, or the like, the plant moulders, or returns again into its earth or dust. Thus, in vegetables burnt by the intensest fire, the earth or matter of the vessels is left entire, and indissoluble by its utmost forces, and consequently the matter thereof is neither water, nor air, nor salt, nor sulphur, but earth alone.

The root or part whereby vegetables are connected to their matrix, and by which they receive their nutritious juice, consists of an infinite number of absorbent vessels, which, being dispersed through the interstices of the earth, attract or imbibe the juices of the same; consequently, every thing in the earth that is dissoluble in water, is liable to be imbibed, as air, salt, oil, fumes of mineral, metal, &c. and of these plants really consist.

These juices are drawn from the earth very crude, but by the structure and fabric of the plant, and the various vessels they are strained through, become changed, further elaborated, secreted, and assimilated to the substance of the plant.

The motion of the nutritious juices of vegetables is produced much like that of blood in animals, by the action of the air; in effect, there is something equivalent to respiration throughout the whole plant.

The discovery of this we owe to the admirable Malpighi, who first observed that vegetables consist of two series or orders of vessels; first, such as receive and convey the alimental juices, answering to the arteries, lacteals, veins, &c. of animals; secondly, tracheæ, or air-vessels, which are long hollow pipes, wherein

wherein air is commonly received and expelled, i. e. inspired and expired; within which tracheæ he shews all the former series of vessels are contained.

Hence it follows, that the heat of a year, nay, of a day, of a single hour or minute, must have an effect on the air included in these tracheæ, i. e. must rarefy it, and consequently dilate the tracheæ, whence arises a perpetual spring or source of action to promote the circulation in plants.

PLANTAGO. Tourn. Inst. R. II. 126. tab. 48. Lin. Gen. Plant. 133. Plantain. To this genus Dr. Linnaeus has joined the Coronopus and Pysillum of Tournefort. The first of these is called Hart's-horn, the latter Fleawort. Of these there are several distinct species, and some varieties; but as they are rarely cultivated in gardens, I shall not enumerate them all here, and shall only mention such of them as grow naturally in England. Of the Plantain there are the following sorts; the common broad-leaved Plantain, called Waybread; the great hoary Plantain or Lamb's-tongue; the narrow-leaved Plantain or Ribwort; and the following varieties have also been found in England, which are accidental; the Besom Plantain, and Rose Plantain. The Plantains grow naturally in pastures in most parts of England, and are frequently very troublesome weeds. The common Plantain and Ribwort Plantain are both used in medicine, and are so well known as to need no description. Of the Coronopus or Buck's-horn Plantain there are two varieties growing in England, viz. the common Buck's-horn, which grows plentifully on heaths every where, and the narrow-leaved Welsh sort which is found upon many of the Welsh mountains. The first of these was formerly cultivated as a salad herb in gardens, but has been long banished from thence for its rank disagreeable flavour; it is sometimes used in medicine. There has been one species of Pysillum or Fleawort found growing naturally in England, which is the sort used in medicine, which was in the earth thrown out of the bottom of the canals which were dug for the Chelsea water-works, where it grew in great plenty. The seeds of this must have been buried there some ages, for no person remembers any of the plants growing in that neighbourhood before. The seeds of this are sometimes used, which are imported from the South of France.

There are several varieties of all these three sorts, which are sometimes preserved in botanic gardens, but having no beauty, they are not admitted into any other, so I shall pass them over here, as being weeds wherever they are permitted to seed.

PLANTAIN-TREE. See MUSA.

PLANTING. Although the method of Planting the various sorts of trees is fully set down under their several articles, where each kind is mentioned, yet it may not be amiss to say something in general upon that head in this place, which shall be treated as briefly as possible. And,

First, the first thing in Planting of trees is to prepare the ground (according to the different sorts of trees intended to be planted) before the trees are taken out of the earth; for you should suffer them to remain as little time out of the ground as possible.

In taking up the trees you should carefully dig away the earth round their roots, so as to come at their several parts to cut them off; for if they are torn out of the ground without care, the roots will be broken and bruised very much to the great injury of the trees. When they are taken up, the next thing is to prepare them for Planting; in doing of which there are two things to be principally regarded; the one is to prepare the roots, and the other to prune their heads, in such a manner as may be most serviceable in promoting the future growth of the trees.

And first as to the roots; all the small fibres are to be cut off as near to the place from whence they are produced as may be (excepting such trees as are to be replanted immediately after they are taken up;) otherwise the air will turn all the small roots and fibres black, which, if permitted to remain on when the tree

is planted, will grow mouldy and decay, and thereby greatly injure the new fibres which are produced, so that many times the trees miscarry for want of duly observing this. After the fibres are cut off, all the bruised or broken roots should be cut smooth, otherwise they are apt to rot and distemper the trees; and all irregular roots which cross each other, and the downright roots, (especially in fruit-trees) must be cut off; so that when the roots are regularly pruned, they may in some measure resemble the fingers of a hand when spread open; then the larger roots should be shortened in proportion to the age and strength of the tree, as also the particular sorts of trees are to be considered; for the Walnut, Mulberry, and some other tender rooted kinds should not be pruned so close, as the more hardy sorts of fruit or forest-trees, which in young fruit-trees, such as Pears, Apples, Plums, Peaches, &c. that are one year old from budding or grafting, may be left about eight or nine inches long; but in older trees they must be left of a much greater length; but this is to be understood of the larger roots only, for the small ones must be quite cut out, or pruned very short. Their extreme parts, which are generally very weak, commonly decay after moving, so that it is the better way entirely to displace them.

The next thing is the pruning of their heads, which must be differently performed in different trees, for the design of the trees must also be considered; if they are fruit-trees, and intended for walls or espaliers, it is the better way to plant them with the greatest part of their heads, which should remain on until the spring, just before the trees begin to shoot, when they must be cut down to five or six eyes (as is fully inserted in the several articles of the various kinds of fruit) being very careful, in doing of this, not to disturb the new roots.

But if the trees are designed for standards, you should prune off the small branches close to the places where they are produced; as also irregular branches which cross each other, and by their motion, when agitated by the wind, rub and bruise their bark, so as to occasion many times great wounds in those places; besides, it makes a disagreeable appearance to the sight, and adds to the closeness of its head, which should always be avoided in fruit-trees, whose branches should be preserved as far distant from each other, as they are usually produced when in a regular way of growth, (which is in all sorts of trees proportionable to the size of their leaves, and magnitude of their fruit) for when their heads are very thick, which is often occasioned by the unskillful shortening of their branches, the sun and air cannot freely pass between the leaves, so that the fruit must be small and ill-tasted. But to return: after having displaced these branches, you should also cut off all such parts of branches, as have by accident been broken or wounded; for these will remain a disagreeable sight, and often occasion a disease in the tree. But you should by no means cut off the main leading shoots, as is by too many practised, for those are necessary to attract the sap from the root, and thereby promote the growth of the tree; for from several experiments which I made in the winter 1729, by cutting off the branches of several sorts of trees, and putting them into phials filled with water, whose tops were closely covered to prevent the evaporating of the water, I found, that those shoots, whose leading buds were preserved, did attract the moisture in much greater quantities than those shoots whose tops were cut off; and from several experiments made by the Rev. Dr. Hales, we find that great quantities of moisture are imbibed at wounds, where branches are cut off; so that by thus shortening the branches, the wet, which generally falls in great plenty during the winter season, is plentifully imbibed, and for want of leaves to perspire it off, mixes with the sap of trees, and thereby distending the vessels, destroys their contracting force, which many times kills the tree, or at least weakens it so much as not to be recovered again for some years, as I have several times observed.

But

But being willing to try this experiment again in the month of October 1733, I made choice of two standard Almond-trees of equal strength and age; these I took up as carefully as possible, and having prepared their roots as before directed, I pruned their heads in the following manner, viz. from one of them I only cut off the small branches, and such as were bruised or broken, but preserved all the strong ones entire; of the other, I shortened all the strong branches, and pruned off the weak and broken shoots, as is the common practice. These two trees I planted in the same soil and to the same situation, gave them both equal attendance, and managed them both as nearly alike as possible; yet in the spring, when these trees began to shoot, that, whose branches were entirely preserved, came out early, continued to shoot stronger, and is at present much larger, and in better health than the other. And since this I have made several other experiments of the like nature, which have constantly succeeded in the same manner, from whence it is reasonable to conclude, that the shortening of the branches is a great injury to all new-planted trees, but especially to Cherries and Horse Chestnuts, which are frequently killed by shortening their large branches when they are removed.

Having thus prepared the trees for Planting, we must now proceed to the placing them into the ground; but before this, I would advise, if the trees have been long out of the ground, so that the roots are dried, to place them in water eight or ten hours before they are planted, observing to put them in such manner, that their heads may remain erect, and their roots only immersed therein, which will swell the dried vessels of the roots, and prepare them to imbibe nourishment from the earth. In fixing of them, great regard should be had to the nature of the soil, which if cold and moist, the trees should be planted very shallow; as also, if it be a hard rock or gravel, it will be much the better way to raise a hill of earth where each tree is to be planted, than to dig into the rock or gravel, and fill it up with earth (as is too often practised), whereby the trees are planted, as it were in a tub, there being but little room for their roots to extend; so that after two or three years growth, when their roots have extended to the sides of the hole, they are stopped by the rock or gravel, can get no farther, whereby the trees will decline, and in a few years die; besides, these holes detain the moisture so, that the fibres of the plants are often rotted thereby. But when they are raised above the surface of the ground, their roots will extend and find nourishment, though the earth upon the rock or gravel be not three inches thick, as may be frequently observed, where trees are growing upon such soils.

The next thing to be observed is to place the tree in the hole in such manner, that the roots may be about the same depth in the ground, as they were growing before they were taken up; then break the earth fine with a spade, and scatter it into the hole, so that it may fall in between every root, that there may be no hollows in the earth (but you should by no means sift or screen the mould, for reasons given in some other places); then having filled in the earth, you should gently tread it close with your feet, but do not make it too hard, which is a very great fault, especially if the ground is strong and inclineable to bind.

Having thus planted the trees, you should provide a parcel of stakes, one of which should be driven down by the sides of the trees, and fastened thereto to support them from being blown down or displaced by the wind; then lay some mulch upon the surface of the ground, about their roots, to prevent the earth from drying.

This is to be understood of standard-trees which cast their leaves; for such as are planted against walls, should have their branches fastened to the wall to prevent the trees from being displaced by the wind; but there is no difference in their management, only to preserve their heads entire, and to place their roots

about five inches from the wall, inclining their heads thereto; and the spring following, just before they shoot, their heads should be cut down to five or six buds, as is fully directed under the several articles of the different kinds of fruit.

As to the watering of all new-planted trees, I should advise it to be done with great moderation, nothing being more injurious to them than over-watering. Examples enough of this kind may have been seen in many parts of England, where there has been plantations made, which have been over-watered, whereby the greatest part of the trees have failed; or those which have survived, have made little progress, occasioned by the abundance of water given to them, whereby the fibres were rotted off as soon as produced. And how can any person imagine that a tree should thrive, when the ground, in which it is planted, is continually floated with water? for by an experiment made by the Rev. Dr. Hales, in placing the roots of a dwarf Pear-tree in water, the quantity of moisture imbibed decreased very much daily, because the sap-vessels of the roots, like those of the cut-off boughs in the same experiment, were so saturated and clogged with moisture, by standing in water, that more of it could not be drawn up. And this experiment was tried upon a tree which was full of leaves, and thereby more capable to discharge a large quantity of moisture than such trees as are entirely destitute of leaves; so that it is impossible such trees can thrive, where the moisture is too great about their roots.

The seasons for planting are various, according to the different sorts of trees, or the soil in which they are planted; for such trees whose leaves fall off in winter, the best time is in the middle or end of October, provided the soil be dry; but for a very wet soil, it is better to defer it until the latter end of February, or the beginning of March; and for many kinds of Evergreens, the beginning of April is by far the best season, though some sorts may be safely removed at Midsummer, provided they are not to be carried very far; but you should always make choice of a cloudy season; if possible, at that time of the year, when they will take fresh root in a few days. And, on the contrary, when these trees are removed in winter, during which time they are almost in a state of rest, they do not take root until the spring advances, and sets the sap in motion; so that many times they die, especially if the winter proves severe.

As to the preparing the soil for Planting, that must also be done to suit the different sorts of trees, some requiring a light soil, others a strong one, &c. But this is fully set down in the several articles of trees, under their proper heads, to which the reader is desired to turn; though for the fruit-trees in general, a fresh soil from a pasture ground, which is neither too light and dry, nor over-strong and moist, but rather a gentle, soft, loamy earth is to be preferred, provided it be exposed some time. And if it be for wall-trees, will be the better if the borders are filled with this earth six or eight feet wide, but it need not be above two feet and a half deep at most; for when the borders are made too deep, the roots of these trees are enticed downward, which is of bad consequence to fruit-trees, as hath been elsewhere observed. The same also must be observed for standard-trees (where fresh earth is brought to the places in which they are planted), not to make the holes too deep, but rather let them have the same quantity of earth in width, which is much to be preferred.

There are several persons who direct the placing of the same side of the tree to the south, which before removing had that position, as a material circumstance to be strictly regarded; but from several trials which I have made, I could not observe the least difference in the growth of those trees which were so placed, and others which were reversed; so that I conclude, it is not of any consequence to observe this method.

The distance which trees should be planted at, must also be proportioned to their several kinds, and the

several purposes for which they are intended, all which is explained under their several heads; but fruit-trees, planted either against walls, or for espaliers, should be allowed the following distances: for most sorts of vigorous-shooting Pear-trees, from thirty-six to forty feet; for Apricots, sixteen or eighteen feet; Apples, twenty-five or thirty feet; Peaches and Nectarines, twelve feet; Cherries and Plums, twenty-five feet, according to the goodness of the soil or the height of the wall. But as these things are mentioned in the several articles of fruit-trees, it will be needless to repeat any more in this place.

What hath been mentioned on this article chiefly relates to fruit-trees and evergreens, for the adorning of gardens; but I shall now proceed to the planting of forest and other trees, which are in all large plantations of parks and extensive gardens the most numerous. The modern practice of transplanting these sorts of trees from hedge-rows and woods of large sizes, and at a great expence, has too generally prevailed in this kingdom, the generality of planters being in too great haste, and by a mistaken notion of saving time, begin by transplanting such large trees as they find on their own estates, or that they can procure in their neighbourhood, and please themselves with the hopes of having fine plantations soon; but if, instead of removing these trees, they would begin by making a nursery, and raising of their trees from seeds, they would set out in a right method, and save a great expence and much time, and they would have the constant pleasure of seeing their trees annually advance in their growth, instead of their growing worse, as will always be the case where old trees are removed, though many persons flatter themselves with the hopes of success, when they find their trees shoot out the following season; and as these will often continue to grow for some years after, so they continue their expectations, till after waiting many years, in which time they might have had seedling trees grown up to a fine size, if they had been sown at the time the large trees were planted, they then find their trees annually decaying, when they most expected their increase; for of all the plantations which I have yet seen of these large trees of any sort, there is scarce one which has ever succeeded. And if those persons who are disposed to plant, would be so kind to themselves as to survey with attention, as many of the modern plantations of this kind as they conveniently can, they will be convinced of the truth of this fact; but there are very few who give themselves time to deliberate before they begin, so that until they meet with disappointments, they scarce reflect on what they are doing. And it too often happens, that the persons employed in the executing, either through ignorance, or some other motive, encourage this practice of Planting.

In some of these plantations, all the Elms which could be procured from the neighbouring hedge-rows have been removed, most of which have been suckers produced from the old stumps, so have scarce any roots: these have, at a great expence, been planted and watered, and perhaps many of them have made considerable shoots, the whole length of the stem at every knot, and many of them have continued ten or twelve years alive, but have not increased in the girth of their stems half an inch, and all that time have been decaying at their heart, and growing hollow; so that when a severe frost in winter, or a great drought in summer, has happened, there has been an almost total destruction of the trees.

In other places I have seen great numbers of tall Oaks transplanted, which have appeared to thrive for some years when first planted; but in five or six years after have begun to decay at their top, and have leisurely died to the ground, than which nothing can be a more disagreeable sight to the owner. And the method which is commonly practised in transplanting of these trees would destroy them, were there a possibility of such large trees surviving their removal, which is, that of cutting off all their branches; for,

were the same practised on a tree of the same age unremoved, it would stint the growth so much as not to be recovered in several years, nor would it ever arrive to the size of such as have all their branches left on them. But the reason given for this practice is, that if the branches were left upon the trees, they could not be supported, the winds would throw them out of the ground; and another (which is bad philosophy) is, that as the roots have been greatly reduced by transplanting, so the heads of the trees should be reduced in the same proportion. As to the first, it must be allowed, that trees which are removed with great heads, are with great difficulty preserved in their upright situation; for the winds will have such power against the branches as to overset the trees, if they are not very strongly supported with ropes. Therefore this may be brought as an objection to the transplanting of large trees, rather than in support of a practice which is so prejudicial to them; and as to the other reason, it has no foundation; for if large amputations are made at the root, there should not be the same practised on the head; because the wounded part of the head will imbibe the air at every orifice, to the great prejudice of the tree. Besides this, if we pay any regard to the doctrine of the circulating of the juices in plants, we must allow, that the heads of the trees are equally useful to nourish the roots, as the roots are to the heads; so that if there is a waste of sap both at the top and bottom of the trees, it must weaken them in proportion. For whoever will be at the trouble to try the experiment on two trees of equal age and health, and to cut the branches off from one, and leave them upon the other at the time of transplanting, if the latter is well secured from blowing down, it will be found to succeed much better than the other; or if the same thing is practised upon two trees left standing, the tree whose branches are cut off, will not make half the progress as the other, nor will the stem increase in its bulk half so fast. Therefore where trees are transplanted young, there will be no necessity for using this unnatural amputation, and the success of these plantations will always give pleasure to the owner. I have seen some plantations of Oak-trees, which were made fifty years ago, and had thriven beyond expectation most part of the time, but are now annually decaying, and seem as if they would not continue many years longer, when the trees on the same soil and in the same situation, which were left standing, are in perfect health and vigour; and some of these transplanted trees which have been cut down, were found to be of little value, their timber being shaken and bad.

It is common to hear persons remarking, that from the present spirit of Planting, great advantages will accrue to the public by the increase of timber; but whoever is the least skilled in the growth of timber must know, that little is to be expected from most of the plantations which have lately been made; for there are few persons who have had this in their view when they commenced planters, and of those few scarce any of them have set out right; for there never was any valuable timber produced from trees which were transplanted of any considerable size, nor is any of the timber of the trees which are transplanted young, equal in goodness to that which has grown from the seeds unremoved. Beside, if we consider the sorts of trees which are usually planted, it will be found, that they are not designed for timber; so that upon the whole, it is much to be doubted, whether the late method of planting has not rather been prejudicial to the growth and increase of timber, than otherwise.

Before I quit this subject of Planting, I must beg leave to observe, that most people are so much in a hurry about Planting, as not to take time to prepare their ground for the reception of trees, but frequently make holes and stick in the trees, amongst all sorts of rubbish which is growing upon the land: and I have frequently observed, that there has not been any care afterward taken to dig the ground, or
root

P L A

root out the noxious plants; but the trees have been left to struggle with these bad neighbours, who have had long possession of the ground, and have established themselves so strongly as not to be easily overcome; therefore, what can be expected from such plantations? This is to be understood of deciduous trees, for the Pines and Firs, if once well rooted in the ground, will soon get the better of the plants and destroy them.

There are some other persons who begin better than the former, and who will be at the expence of preparing the ground and of Planting their trees, but afterward take very little care of them; so that it is common to see them overgrown with weeds in a year after they are planted, whereby the trees receive so much injury as to retard their growth, and many times, if the trees are young, they are totally destroyed. Therefore I would advise every person who proposes to plant, to prepare the ground well before-hand, by trenching or deep ploughing it, and clearing it from the roots of all bad weeds; for by so doing, there will be a foundation laid for the future success of the plantation. Also I advise no person to undertake more of this work than he can afterward keep clean, for all plantations of deciduous trees will require this care, or at least for seven years after they are made, if they hope to see the trees thrive well. Therefore all small plantations should have the ground annually dug between the trees; and as to those which are large, it should be ploughed between them. This will encourage the roots of the trees to extend themselves, whereby they will find a much greater share of nourishment, and by loosening the ground, the moisture and air will more easily penetrate to the roots, to the no small advantage of the trees. But besides this operation, it will be absolutely necessary to hoe the ground three or four times in summer, either by hand or the hoe-plough. This I am aware will be objected to by many, on account of the expence; but if the first hoeing is performed early in the spring, before the weeds have gotten strength, a great quantity of ground may be gone over in a short time; and if the season is dry when it is performed, the weeds will presently die after they are cut; and if this is repeated before the weeds come up again to any size, it will be found the cheapest and very best husbandry; for if the weeds are suffered to grow till they are large, it will be a much greater expence to root them out, and make the ground clean; besides, the weeds will rob the trees of great part of their nourishment. I have sometimes been told, That it is necessary to let the weeds grow among trees in summer, in order to shade their roots, and keep the ground moist, but this has come from persons of no skill; but as others may have been deceived by such advice, I imagine it may not be improper to give some answer to this. And here I must observe, That if weeds are permitted to grow, they will draw away all moisture from the roots of the trees for their own nourishment, so that the trees will be thereby deprived of the kindly dews and the gentle showers of rain, which are of great service to young plantations; and these will be entirely drawn away by the weeds, which will prevent their penetrating the ground, so that it is only the great rains which can descend to the roots of the trees. And whoever has the least doubt of this matter, if they will but try the experiment, by keeping one part of the plantation clean, and suffer the weeds to grow on another, they will soon be convinced of the truth by the growth of the trees. And though this cleaning is attended with an expence, yet the success will overpay this, beside the additional pleasure of seeing the ground always clean.

In the disposition of trees in parks, and of shrubs and trees in gardens, there are very few of those who call themselves designers, who have had much regard to this particular; for in most of the modern plantations, it is not uncommon to see an Oak, an Elm, or some other large-growing tree planted where a Rose-bush, a Honey-suckle, or Sweet-briar, might with more propriety occupy the space: so that in a

P L A

few years, if these large trees are left growing, the whole plantation must make a disagreeable appearance; but having already mentioned these things under the article of GARDENS, I shall not enlarge farther on them here.

PLANTING REVERSE: Dr. Agricola tells us, That he has made several experiments on the branches of foreign trees, as well Orange as Laurel, which he performed after the manner following; he first stripped the branches of all the leaves; then he bent and tied them, dressed them with his noble mummy, and planted them the reverse way, so that nothing was to be seen of all the branches but the great ends, and kept them during the winter in his stove.

He adds, That those who have a mind to raise trees this way, which he calls monstrous fruit-trees, may raise Apples, Pears, Cherries, Apricots, Peaches, Mulberries, Walnut-trees, &c. also Rose-trees, Gooseberry bushes, &c. which he directs to do something more at large, as follows:

Take those branches that are furnished with long side shoots or twigs, and bend the side twigs in the joints toward the great branches, and tie them together with bass or packthread; then dress them with mummy, either with a brush only near the ligature, and here and there on the joints, or dip them entirely into it; then having made a deep hole in the ground set the branches the reverse way, so that nothing but the long end of the branch appears above ground, the rest being covered with good, fat, and well broken earth. This being done, the little branches will take root in the joints every where; then the buds will begin to shoot, so that you may see fifty or sixty more branches spring up, making an agreeable as well as monstrous figure.

Mr. Fairchild of Hoxton had begun to put the same into practice, and he gives directions for performing it as follows:

First, to make choice of a young tree of one shoot, either of Alder, Elm, or Willow, or any other tree that will take root easily by laying, and to bend the extreme part of the shoot gently down into the earth, and so let it remain till it has taken root, so that the plant then will resemble an arch or bent bow above the ground.

When this top end has well struck new roots, to dig about the first root, and raise it gently out of the ground, till the stem is upright, and so stake it up, otherwise it will be apt to bend.

Then to prune those roots that are erected in the air, from the bruises and wounds which they received in being dug up, and do over with a brush the pruned parts with the following composition, moderately warm:

Take four ounces of tallow, four ounces of bees-wax, two ounces of resin, and two ounces of turpentine, melted together in a pipkin.

After this prune off all the buds or shoots that are upon the stem or plant, and dress the wound with the same composition, to prevent any collateral shootings, that may spoil the beauty of the stem.

Besides, care is to be taken, that the new-growing roots of this reversed plant be well nourished; and therefore that part of the shoot which was the larger, is to be cut away a little below the earth, that the stem may be better nourished, and its roots translated. These experiments are curious but not useful, because these reversed trees never shoot perpendicular, but their branches incline to the ground, retaining their former method of growing.

PLATANUS. Tourn. Inst. R. H. 590. tab. 363. Lin. Gen. Plant. 954. [πλάτανος, of πλατύς, broad, because the leaves of this tree are broad.] The Plane-tree.

The CHARACTERS are,

It hath male and female flowers growing separate on the same tree. The male flowers are collected in a round ball; they have no petals, but have very small empalements, which have oblong coloured stamina, terminated by four-cornered summits. The female flowers have small scaly empalements,

empalements, and several small concave petals, with several awl-shaped germen sitting upon the styles, crowned by recurved stigmas; these are collected in large balls. The germen afterward turns to a roundish seed sitting upon the bristly style, and surrounded with downy hairs.

This genus of plants is ranged in the eighth section of Linnæus's twenty-first class, which includes those plants which have male and female flowers separated on the same plant, whose male flowers have many stamina.

The SPECIES are,

1. PLATANUS (*Orientalis*) foliis palmatis. Hort. Cliff. 447. *Plane-tree with hand-shaped leaves.* Platanus Orientalis verus. Park. Theat. 1427. *The true Eastern Plane-tree.*
2. PLATANUS (*Occidentalis*) foliis lobatis. Hort. Cliff. 447. *Plane-tree with lobated leaves.* Platanus Occidentalis aut Virginienfis. Park. Theat. 1427. *Occidental or Virginian Plane-tree.*

These two are undoubtedly distinct species, but there are two others in the English gardens, which I suppose to be varieties that have accidentally risen from seed; one is titled the Maple-leaved Plane-tree, and the other is called the Spanish Plane-tree.

The first sort, or Eastern Plane-tree, grows naturally in Asia, where it becomes very large; the stem is tall, erect, and covered with a smooth bark, which annually falls off; it sends out many side branches, which are generally a little crooked at their joints; the bark of the young branches is of a dark brown, inclining to a purple colour; they are garnished with leaves placed alternate; their foot-stalks are an inch and a half long; the leaves are seven inches long and eight broad, deeply cut into five segments, and the two outer are slightly cut again into two more; these segments have many acute indentures on their borders, and have each a strong midrib, with many lateral veins running to the sides; the upper side of the leaves are of a deep green, and the under side pale. The flowers come out upon long foot-stalks or ropes hanging downward, each sustaining five or six round balls of flowers; the upper, which are the largest, are more than four inches in circumference; these sit very close to the foot-stalks. The flowers are so small as scarce to be distinguished without glasses; they come out a little before the leaves, which is in the beginning of June; and in warm summers the seeds will ripen late in autumn, and if left upon the trees will remain till spring, when the balls fall to pieces, and the bristly down which surrounds the seeds, help to transport them to a great distance with the wind. The second sort grows naturally in most parts of North America; this tree also grows to a large size, the stem very strait, and of equal girt most part of the length; the bark is smooth, and annually falls off like that of the other; the branches extend wide on every side; the young ones have a brownish bark, but the old ones have a gray bark; the foot-stalks of the leaves are three inches long; the leaves are seven inches long, and ten broad; they are cut into three lobes or angles, and have several acute indentures on their borders, with three longitudinal midribs, and many strong lateral veins. The leaves are of a light green on their upper side, and paler on their under. The flowers grow in round balls like the former, but are smaller. The leaves and flowers come out at the same time with the former, and the seeds ripen in autumn.

That which is called the Maple-leaved Plane, is certainly a seminal variety of the Eastern Plane, for the seeds which scattered from a large tree of this kind in the Chelsea Garden have produced plants of that sort several times. This differs from the two sorts before-mentioned, in having its leaves not so deeply cut as those of the Eastern Plane, but they are divided into five segments, pretty deep, but are not lobed as those of the Occidental Plane. The foot-stalks of the leaves are much longer than those of either of the former, and the upper surface of the leaves is rougher, so that any person might take them

for different species, who had not seen them rise from the same seeds.

The Spanish Plane-tree has larger leaves than either of the other sorts, which are more divided than those of the Occidental Plane-tree, but not so much as the Eastern. Some of the leaves are cut into five and others but three lobes; these are sharply indented on the edges, and are of a light green; the foot-stalks are short, and covered with a short down. This is by some called the middle Plane-tree, from its leaves being shaped between those of the two other sorts. It grows rather faster than either of the other sorts, but I have not seen any very large trees of this kind.

The first sort was brought out of the Levant to Rome, where it was cultivated with much cost and industry. The greatest orators and statesmen among the Romans took great pleasure in their villas, which were surrounded with Platani; and their fondness for this tree became so great, that we frequently read of their irrigating them with wine instead of water. Pliny affirms, that there is no tree whatsoever, which so well defends us from the heat of the sun in summer, nor that admits it more kindly in winter, the branches being produced at a proportionable distance to the largeness of their leaves (which is what holds through all the different sorts of trees yet known) so that when the leaves are fallen in winter, the branches growing at a great distance, easily admit the rays of the sun.

This tree was afterwards brought to France, where it was cultivated only by persons of the first rank; and so much was the shade of it prized, as that if any of the natives did but put his head under it, they exacted a tribute from him.

It is generally supposed, that the introduction of this tree into England is owing to the great Lord Chancellor Bacon, who planted a noble parcel of them at Verulam, which were there very flourishing some years since, but have lately been destroyed. But notwithstanding its having been so long in England, yet there are but very few large trees to be seen of it at present; which may, perhaps, be owing to the great esteem the persons of the last age had for the Lime-tree, which was a fashionable tree at that time, and being much easier to propagate, and of a quicker growth during the three or four first years than the Plane-tree, thereby it became the most common tree for planting of avenues and shady walks near habitations in England. But since the defects of that tree have been more generally discovered, the Elm has had the preference, and is now the most commonly planted for such purposes.

However, notwithstanding what has been said of the Plane-tree, of its backwardness in coming out in the spring, and the sudden decay of its leaves in autumn, yet for the goodly appearance, and great magnitude to which it will grow, it deserves a place in large plantations, or shady recesses near habitations; especially if the plantation be designed on a moist soil, or near rivulets of water, in which places this tree will arrive to a prodigious magnitude.

We read of one of these trees, which was growing at a villa of the Emperor Caligula, whose trunk was so large, as when hollowed, to make room therein, capacious enough to entertain ten or twelve persons at a repast, and for their servants to wait upon them. And there is mention made of one of these trees, which was growing in the Eastern country, which was of so great a magnitude, that Xerxes made his army (which consisted of seventeen hundred thousand men) halt for some days, to admire the beauty and tallness of this tree; and became so fond of it, as to take his own, his concubines, and all the great persons jewels to cover it; and was so much enamoured with it, that for some days, neither the concern of his grand expedition, nor interest, nor honour, the necessary motion of his prodigious army, could dissuade him from it; he fliled it, his Mistress, his Minion, his Goddes; and when he was obliged to part with it, he caused a figure of it to be

stamped

stamped on a gold medal, which he continually wore about him.

And such was the esteem which the people of Asia had for this tree, that wherever they erected any sumptuous buildings, the porticoes, which opened to the air, terminated in groves of these trees.

The Eastern Plane-tree is propagated either from seeds, or by layers, the latter of which is generally practised in England; though the plants thus raised seldom make so large strait trees, as those which are produced from seeds; but it has been generally thought, that the seeds of this tree were not productive, because they have not been sown at a proper season, nor managed in a right manner; for I have had thousands of the young plants spring up from the seeds of a large tree, which scattered upon the ground in a moist place; and I since find, that if these seeds are sown soon after they are ripe, in a moist shady situation, they will rise extremely well; and the plants thus obtained, will make a considerable progress after the second year, being much hardier and less liable to lose their tops in winter, than those which are propagated by layers. And since the seeds of this tree frequently ripen well in England, they may be propagated in as great plenty as any other forest-tree.

The Virginian Plane-tree will grow extremely well from cuttings, if they are planted the beginning of October upon a moist soil; and if they are watered in dry weather, will make a prodigious progress; so that in a few years from the planting, they will afford noble trees for planting of avenues, and other shady walks; and their trunks are perfectly strait, growing nearly of the same size to a considerable height, there being the least difference in the girth of this tree, for several yards upwards, of any other sort of tree whatsoever. The Hon. Paul Dudley, Esq; in a letter to the Royal Society, mentions one of these trees, which he observed in New England, whose girth was nine yards, and held its bigness a great way up, which tree, when cut down, made twenty-two cords of wood. He also says, in the same letter, That he had propagated many of these trees by cutting off sticks of five or six feet long, and setting them a foot deep into the ground in the spring of the year, when the season was wet, and that they always thrive best in a moist soil.

All the sorts are propagated very easily by layers, every twig of them will take root, if they are but pegged down and covered with earth; these layers will be well rooted in one year, when they should be cut off from the old trees or stools, and planted in a nursery, where they may remain two or three years to get strength, after which they may be transplanted where they are to remain, for the younger these trees are planted the better they will thrive. An experiment of this I made in 1731, when I planted four of these trees, one of each sort, in the same soil and situation, at about twenty feet distance from each other; one of which, viz. the Spanish Plane, whose stem was eight inches in girth; next to this, I planted one of the Maple-leaved Plane-tree, whose girth was not three inches, but the latter is now much larger than the former, and gains more in one year than the other does in three; and the two others which were of a middle size, have grown in a mean proportion between them.

PLOUGHING OF LAND.

There is not a greater improvement of arable land than that of well ploughing it, by which the soil is pulverized, and rendered fit to receive the fibres of the plants; and the oftener this is repeated, and the better it is performed, the greater improvement is made in the land. But there are not many of the practitioners of the art of husbandry, who attend enough to this part of it, most of them contenting themselves with going on in the old beaten road of their predecessors; so that the only persons who have made great improvement in this part of agriculture, are the great gardeners, who cultivate most of their land with the plough; therefore they have imitated, as near as possible, the use of the spade in labouring of their ground.

The difference between digging of land with the spade, and that of ploughing, consists in the parts of the earth being much more divided by the former, than the latter method; therefore those gardeners, who are curious in the working of their land, oblige their labourers to spit the ground as thin as possible, that there may remain no large clods unbroken; so, when land is ploughed, the same regard should be had to break and pulverize the parts as much as possible; for when there are great clods left unbroken, the fibres of plants never penetrate farther than the surface of them; so that all the salts included in these lumps of earth are locked up, that the plants can receive no benefit from them. And these clods, in proportion to their size, make such interstices, that the air often penetrates through, and greatly injures the tender fibres of the roots. Therefore the oftener the land is ploughed, and the more the parts are separated and pulverized, the better will the plants be nourished and fed; but particularly in all strong land, this part of husbandry will be the most beneficial; but this cannot be effected under four or five ploughings, and by using such ploughs as have either two or four coulter, which will cut and separate the clods much better than it can be performed by the common plough; and in the operation, great care should be had to the breadth of the furrow, for when these are made too broad, it will be impossible to break and separate the parts sufficiently. In some counties, where the husbandmen are not very expert in the use of the plough, I have seen gentlemen oblige them to plough by a line, and they have set out the exact width of each furrow. This not only adds a neatness to the ground, but likewise, by keeping the furrows strait, and at equal distances, the land will be more equally worked; but many of the good ploughmen in the counties near London, will direct the plough as strait by their eye, as if they were to use a line.

Another thing to be observed in ploughing of land is that of going to a proper depth, for if the surface only be broken up and pulverized, the roots of whatever plants are sown upon it will in a very short time reach the bottom, and meeting with the hard unbroken soil, they are stopped from getting farther, and of consequence the plants will stint in their growth; for there are few persons who have attended enough to the downright growth of the roots of plants, and only have had regard to the roots of those plants, which are of a strong fleshy substance, and are called tap-roots, being in form of Carrots. These they suppose will require to have the land wrought to a greater depth, that the roots may run down, and be the longer, for in that particular their goodness consists. But they do not think that the small fibrous-rooted plants ever require so much depth to run into the ground; in this they are greatly mistaken, for I have traced the small fibres of Grass and Corn above three feet deep in the ground. And if any person is curious to observe the length of the fibres of plants, if they will but plant one of each sort into a small pot of earth, and keep them duly watered till the plants are advanced to flower, and then turn them out of the pots carefully, so as not to break any of the fibres of the roots, and after separating the earth from them, measure the length of their roots, they will be found much greater than most people imagine. I have myself frequently traced the roots of plants, which have surrounded the pots upward of twelve times; and the roots of some strong-growing plants, which have gotten through the holes in the bottom of flower-pots, have in three months time extended themselves ten or eleven feet from the plant; therefore the deeper the ground is laboured, the greater benefit the plants will receive from it: but it must be understood of such land as the staple is deep enough to admit of this, for if the soil is shallow, and either gravel, chalk, or stone lie beneath, it will be very imprudent to turn up either of these; therefore the depth of the furrows in such lands, must be determined by the staple of the land. By the word staple must be understood all tha:

depth of soil next the surface, which is proper for the growth of vegetables. Where clay is next the staple, provided it is not of the blue or iron-mould sort, there will not be the same danger of going a little deeper than the staple, as in either of the before-mentioned sorts of land; for if the clay be of a fat nature, when it hath been well exposed to air, and often laboured, it will be capable of affording a large share of nourishment to the crops.

If between each ploughing of the land a harrow with long teeth is made use of to tear and break the clods, it will be of great service to the land; for the more it is stirred by different instruments, the better will the parts be separated and pulverized; so that the common method, as practised by the farmers, when they fallow their land, is far from answering the intention, for they plough up the ground, leaving it in great clods for some months, and frequently, during this time, Thistles and all bad weeds are suffered to grow upon the land, to exhaust the goodness of it; and perhaps, just before the seeds are sown, they give it two more ploughings. This is what the farmers call good husbandry; but if instead of this method they would labour the ground often with the plough, a harrow, and heavy roller, to break and separate the parts, and never suffer any weeds to grow upon the land during its lying fallow, I am sure they would find their account in it; first, by the growth and increase of their crops, and afterward by a saving in the weeding; for if no weeds are suffered to grow to shed their seeds, during the time of fallowing the land, there will but few come up when the ground is sown, in comparison with what would otherwise be in the common husbandry.

In many of the old gardens near London, which are occupied by the kitchen-gardeners, when the upper surface of the ground is exhausted by the continual crops which they get from it, it is a common method to trench the ground two or three spades depth, and turn the bottom soil upward; and by this the land is fresh, and produces very good crops for some years after. And in imitation of this many of the farming gardeners, who make use of the plough, have two or three men following the plough in the furrows, who turn up a spit in the bottom of each furrow; and where the soil is good, they throw it on the surface, but if otherwise, they level it in the bottom, and this loosening of the ground renders it capable of admitting the roots of the plants.

The ploughing already mentioned is intended to prepare the land for the reception of the seeds which are proposed to be sown, and as was before observed, the oftener and better this is performed, the more the land will produce. But, beside this, there will be a necessity for stirring the ground to destroy the weeds, after the crop is growing; for if the weeds are suffered to grow with the crop, they will draw away most of the nourishment, and greatly lessen their produce. Therefore in gardens this work is generally performed by hand, with an instrument called a hoe, unless when the ground is very stiff, and subject to bind; in which case it will be proper to make use of forks to break and loosen the earth between the crops, and the oftener this is repeated, the better will the crops succeed, and this husbandry I have seen attended with great advantage. But in the large open fields of Beans, Peas, and other large-growing plants which are planted in rows, the ground between may be frequently stirred with a small swing-plough, which will destroy the weeds, pulverize the ground, and give nourishment to the crop; for as all land is apt to bind, or the parts coalesce by lying unstirred, the more and oftener it is stirred, the better it will be kept loose, and thereby rendered proper for the growth of plants. This sort of ploughing is termed horse-hoeing, and there being a particular treatise upon this sort of husbandry written by Mr. Jethro Tull, of Shelbourn, in Berkshire, in which the instruments are figured and described, I shall refer those, who are desirous to practise this husbandry, to the book itself, and shall only take notice, that although the in-

strument used in this operation is a plough, yet it is termed hoeing, as it is intended to destroy the weeds, and to stir the ground but a small depth, to distinguish it from the common ploughing to prepare the land for the crop.

PLUMBAGO. Tourn. Inst. R. H. 140. tab. 58. Lin. Gen. Plant. 156. Leadwort.

The CHARACTERS are,

The flower has a tubulous, five-cornered, permanent empalement of one leaf, which is indented at the top into five parts; it hath one petal which is funnel-shaped, and a cylindrical tube which is narrow at the top. The brim is cut into five parts which are oval and spreading; it has five oval-shaped stamina situated in the tube, sitting upon the valves of the nectarium, which includes the germen. The small oval germen sustains a single style the length of the tube, crowned by a slender five-pointed stigma. The germen afterward becomes a single oval seed included in the empalement.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes the plants whose flowers have five stamina and one style.

The SPECIES are,

1. PLUMBAGO (*Europæa*) foliis amplexicaulibus. Hort. Cliff. 53. *Leadwort with leaves embracing the stalks.* Plumbago quorundam. Clus. Hist. 123. *Leadwort or Toothwort.*
2. PLUMBAGO (*Zeylanica*) foliis petiolatis ovatis glabris, caule geniculis gibbosis. Lin. Sp. 215. Hort. Cliff. 53. *Leadwort with leaves having foot-stalks.* Plumbago Americana, betæ folio ampliori. Plum. Cat. *American Leadwort with a larger Beet leaf.*

These are all the sorts which I have observed in the English gardens. The first sort grows naturally in the south of France, in Italy, and Spain; it hath a perennial root, which strikes deep into the ground, from which arise many slender stalks about three feet and a half high, which are channelled, and garnished with oval spear-shaped leaves about three inches long and two broad, whose base embrace the stalks; they are smooth, entire, and of a grayish colour. The upper part of the stalks send out many side branches which are slender, and garnished with small leaves. These, and also the principal stalks, are terminated by tufts of either blue or white flowers, which are small, funnel-shaped, and have pretty long tubes, and are succeeded by oblong, rough, hairy seeds. This plant seldom flowers till toward the end of October in England, and unless the autumn proves warm, does not flower here, so never produces ripe seeds. There is a variety of this with white flowers and pale stalks, which is supposed to have risen from the seeds of the former.

The stalks of this decay in the winter, and new ones come up the following spring; they are propagated here by parting of their roots, which send out heads in plenty. These may be divided at any time when the weather is mild, from the time the stalks decay, till the roots begin to shoot in the spring; it should have a light soil and a warm situation, otherwise it will not flower here. The roots should be allowed room to spread, and the stalks require support, and if the plants are kept clean from weeds, and the ground between them dug every winter, it is all the culture they require.

It is called Dentillaria or Toothwort by many authors, who recommend its virtues in curing the tooth-ach, being of a hot caustic nature like Pellitory of Spain.

The second sort grows naturally in both Indies; this is a perennial plant, with a strong fibrous root, from which arise many slender stalks, which grow near four feet high, garnished with smooth, oval, spear-shaped leaves about three inches long, and one and a half broad near their base, ending in acute points, which are placed alternate, standing upon short foot-stalks. The upper part of the stalks divide into small branches, garnished with small oval leaves, and terminate in spikes of flowers, which have long slender tubes, cut into five segments at the brim, which spread open; these are succeeded by oblong seeds covered with the prickly empalement. The upper part of

the

the stalks, and the empalements of the flowers are very glutinous, sticking to the fingers if touched, and the small flies which settle upon them are fastened, so cannot get off again. This plant is too tender to thrive in the open air in England, so requires to be kept in a moderate stove, where they will continue flowering great part of the year; and those flowers which appear early in the summer, will be succeeded by ripe seeds in autumn.

This is propagated by seeds, which should be sown on a good hot-bed in the spring, where the plants will come up in about five or six weeks. When these are fit to remove, they should be each planted into a separate small pot filled with light loamy earth, and plunged into a hot-bed of tan, observing to screen them from the sun till they have taken new root; afterward they must be treated like other plants from the same country. In the summer they should have a large share of fresh air admitted to them in warm weather, and require water every other day in moderation. In winter they should be kept in a moderate temperature of warmth, and must be more sparingly watered. With this management the roots will abide several years, and produce plenty of flowers and seeds.

PLUM-TREE. See PRUNUS.

PLUMERIA. Tourn. Inst. R. H. 659. tab. 439. Lin. Gen. Plant. 263. Red Jasmine; in French, *Fran-gipavier*.

The CHARACTERS are,

The flower has a small obtuse empalement divided into five parts; it hath one funnel-shaped petal, with a long tube enlarging upward, cut into five oblong oval segments at the top, which spread open; it hath five awl-shaped stamina situated in the center of the tube, terminated by summits which close together, and an oblong bifid germen with scarce any style, crowned by a double acute stigma. The germen afterward becomes a long, swelling, acute-pointed capsule with one cell, filled with winged seeds placed over each other like scales of fish, fastened at their base to the sides of the capsule.

This genus of plants is ranged in the first section of Linnæus's fifth class, which contains those plants whose flowers have five stamina and one style.

The SPECIES are,

1. PLUMERIA (*Rubra*) foliis ovato-oblongis, petiolis biglandulosis. Hort. Cliff. 76. *Plumeria* with oblong oval leaves, whose foot-stalks have two glands. *Plumeria* flore roseo odoratissimo. Inst. R. H. 659. *Plumeria* with a Rose-coloured sweet-scented flower, commonly called in the West-Indies Red Jasmine.
2. PLUMERIA (*Incarnata*) foliis ovato-oblongis, ramis patulis, floribus corymbosis. *Plumeria* with oblong oval leaves, spreading branches, and flowers growing in a corymbus. *Plumeria* flore majore odorato & incarnato. *Plumeria* with a larger sweet-scented and incarnate flower, called in the West-Indies the Japan-tree.
3. PLUMERIA (*Alba*) foliis lanceolatis revolutis, pedunculis superne tuberosis. Lin. Sp. Plant. 410. *Plumeria* with spear-shaped leaves which turn backward, whose foot-stalks have swellings on the upper side. *Plumeria* flore niveo, foliis longis angustis & acuminatis. Inst. R. H. *Plumeria* with a snowy flower, and long narrow-pointed leaves.
4. PLUMERIA (*Nivea*) foliis lanceolatis petiolatis obtusis. Lin. Sp. Plant. 210. *Plumeria* with spear-shaped obtuse leaves having foot-stalks. *Plumeria* flore niveo, foliis brevioribus & obtusis. Inst. R. H. *Plumeria* with a snowy flower, and shorter blunt leaves.
5. PLUMERIA (*Africana*) foliis lineari-lanceolatis longifimis. *Plumeria* with very long, narrow, spear-shaped leaves.

The title of this genus was given to it by Dr. Tournefort, in honour of Father Plumer, who was botanist to the late King of France, and a long time in America searching after new plants; and has published a catalogue of the plants he discovered, with several new genera which he constituted, in two volumes in folio, with figures and descriptions of many of the plants.

The first sort grows naturally in the Spanish West-Indies, from whence it was transplanted into most of the islands in the West-Indies, where it is cultivated in the gardens for ornament. It rises to the height of eighteen or twenty feet; the stalk is covered with a dark green bark, having marks where the leaves are fallen off. The stalks are succulent, and abound with a milky juice, but within they are somewhat ligneous. Toward the top they put out a few thick succulent branches, which are garnished at their ends with oval oblong leaves of a light green colour, having a large midrib and many transverse veins; these are full of a milky juice. At the ends of the branches come out the flowers in clusters; they are shaped like those of the Oleander or Rose Bay, having one petal which is tubulous, and cut into five oval obtuse segments which spread open, of a pale red colour, and have an agreeable odour. When the flowers are past, the germen becomes a long swelling pod filled with flat winged seeds, lying over each other like the scales of fish. It usually flowers here in July and August, but is never succeeded by pods in England.

The second sort I received from the island of St. Christopher's by the name of Japan-tree; this sort is very rare in the English settlements at present, having been but lately introduced from the Spanish West-Indies. It is in leaf and stem very like the first, but the stalks do not rise so high; they divide into strong spreading branches, which are filled with a milky juice; the leaves are of a thicker consistence than those of the first, and their veins are larger; the flowers of this are of a paler colour, and are produced in much larger clusters. It is very common to have upward of twenty of these flowers open in one bunch, and a number to succeed these as they decay, so that the clusters have continued in beauty upward of two months, during which time they make a most beautiful appearance in the stove, and have a very agreeable flavour.

The third sort grows plentifully at Campeachy, from whence the late Dr. Houstoun sent the seeds. He also observed some plants of this kind at Jamaica. This is not near so beautiful as the two former sorts, the flowers being smaller, and produced in less bunches, and are moreover of short duration. But for the beauty of their stems and leaves, and for the sake of variety, they deserve room in every curious collection of plants.

The fourth sort was discovered by Dr. Houstoun, growing in great plenty near Carthagen in the Spanish West-Indies, from whence he sent the seeds to England. This sort produces small white flowers, resembling those of the third, so is less valuable than the two first.

The seeds of the fifth sort were sent me by Mr. Richard, gardener to the King of France at Versailles; they were brought from Senegal by Monsieur Adanson, who was some years in that country in search of plants. This hath a stalk very like the first sort, but the leaves are nine or ten inches long, and not more than two inches broad; they are thick, succulent, and full of a milky juice, a little roundish at their base, but end in acute points. The flowers of this sort are said to be yellow, but as the plants have not yet flowered here, I can give no farther account of them.

All these plants may be propagated by seeds, which must be procured from the countries where they naturally grow; they should be sown in pots filled with light earth, and plunged into a hot-bed of tanners bark; and when the plants are come up about two inches high, they should be transplanted into separate small pots filled with light sandy earth, and plunged into the hot-bed again, observing to shade them from the heat of the sun in the middle of the day, until they have taken root; but they must not have much water, for as all the sorts are very succulent, being full of a milky juice, somewhat like the Euphorbiums, moisture will cause them to rot. In hot weather the plants should have a pretty large share of fresh air admitted

P O D

admitted to them, by raising the glasses of the hot-bed every day, in proportion to the warmth of the season, to prevent their drawing up weak. Toward Michaelmas, when the nights begin to be cold, the plants should be removed into the stove, and plunged into the bark-bed, where they must remain during the winter. As these plants all cast their leaves in the middle of winter, and continue destitute of them till about the beginning of May, so during that time, they should be watered very sparingly, because they are in more danger of rotting, while they are in a less active state, by too much moisture, than when they are furnished with leaves, through which the moisture is more freely perspired.

All these sorts are too tender to thrive in the open air of this country in the summer season, therefore should be constantly preserved in the stove, where, in warm weather, they must have a large share of free air, but in cold weather they must be kept very warm. While they are young, it will be proper to continue them in the bark-bed; but when they have obtained strength, they may be placed in a dry stove, where they will thrive well, provided they are kept in a moderate temperature of heat, and have not too much water.

These plants may also be propagated by cuttings, which should be taken from the old plants two months before they are planted, during which time they should be laid on the flues in the stove, that the part which joined to the old plant may be healed over before they are planted, otherwise they will rot. These cuttings should be planted in small pots filled with light sandy earth, and plunged into a moderate hot-bed of tanners bark, observing to shade them in the heat of the day from the sun, and refresh them once in a week or ten days with water, but it must be given to them sparingly each time. If the cuttings succeed, they will have taken root in about two months, when they should have a larger share of air to harden them by degrees to bear the sun and air, and afterward may be treated as the old plants.

The milky juice of these plants is very caustic, and reckoned poisonous. In cutting off any of the branches of the plants, if the knife be not immediately cleaned, the juice will corrode it, and turn the blade almost black in a very little time, so as not to be cleaned off again; and if dropped on linen will cause it to wash in holes, equal to aquafortis.

PODOPHYLLUM. Lin. Gen. Plant. 571. Anapodophyllum. Tourn. Inst. R. H. 239. tab. 122. Duck's-foot, or May Apple.

The CHARACTERS are,

The bud of the flower is inclosed in a large, three-leaved, coloured empalement in form of a spatula or sheath. The flower has nine roundish concave petals which are plaited on their borders, smaller than the empalement; it has a roundish germen without a style, crowned by a plaited obtuse stigma. The germen afterward turns to an oval capsule of one cell, crowned by the stigma, filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's thirteenth class, which includes those plants whose flowers have many stamina and one style.

We have but one SPECIES of this genus at present in the English gardens, viz.

PODOPHYLLUM (Peltatum) foliis peltatis lobatis. Lin. Sp. Plant. 505. Duck's-foot with target-shaped leaves having lobes. Anapodophyllum Canadense Morini. Tourn. Inst. R. H. 219. Canada Duck's-foot of Morinus.

This plant grows naturally in many parts of North America. The root is composed of many thick tubers which are fastened together by fleshy fibres, which spread, and propagate greatly under ground, sending out many smaller fibres which strike downward. In the spring arise several foot-stalks about six inches high, which divide into two smaller, each sustaining one leaf, composed of five, six, or seven lobes, the five middle being deeply indented at the top; these join together at their base, where the foot-stalk meets,

P O I

which is fastened to the under side of the leaf like the handle of a target; the leaves are smooth, and of a light green. At the division of the foot-stalk comes out the flower, with a large empalement covering it like a sheath; the flower hath nine pretty large concave white petals, which are roundish at the top, and plaited on their borders. In the center is situated a large, roundish, oval germen, crowned by a plaited obtuse stigma, and surrounded by a great number of short stamina, terminated by oblong, erect, yellow summits. The flowers appear in May, and when they fall off, the germen swells to a fruit of the size and shape of the common Hip or fruit of the wild Rose. This is at first green, but when ripe changes to a yellow colour, inclosing several roundish seeds fastened to the placenta.

This plant propagates so fast by its creeping roots, as that few persons are at the trouble of sowing the seeds. Every part of the root will grow, so they may be annually parted, either in autumn when their leaves decay, or in the spring just before the roots begin to shoot; they require no other culture but to keep them clean from weeds. It loves a light loamy soil and a shady situation, and is so hardy as seldom to be injured by the frost.

POINCIANA. Tourn. Inst. R. H. 619. tab. 391. Lin. Gen. Plant. 462. Barbadoes Flower-fence, or Spanish Carnations; in French, *Poincillade*.

The CHARACTERS are,

The empalement of the flower is composed of five oblong concave leaves which fall off. The flower has five unequal petals; four of them are nearly equal and roundish, but the fifth is larger, deformed, and indented. It hath ten long, bristly, rising stamina, terminated by oblong summits, and an awl-shaped declining germen which sits upon the style the length of the stamina, and is crowned by an acute stigma. The germen afterward becomes an oblong compressed pod, with several transverse partitions; in each of these is lodged a single flattish seed.

This genus of plants is ranged in the first section of Linnæus's tenth class, which contains those plants whose flowers have ten stamina and one style.

We have but one SPECIES of this genus in the English gardens, viz.

POINCIANA (Pulcherrima) aculeis geminis. Hort. Upsal. 101. Flower-fence with double spines. Poinciana flore pulcherrimo. Tourn. Inst. R. H. 619. *Poinciana with a most beautiful flower.*

There are two varieties of this which were discovered by the late Dr. Houstoun in the Spanish West-Indies. One of these hath a red, and the other a yellow flower; but as there appears to be no other difference in the plants from the common sort, they must be supposed only accidental variations which have risen from seeds.

This plant grows naturally in both Indies; it is planted in hedges to divide the lands in Barbadoes, from whence it had the title of Flower-fence; it is also called Spanish Carnations by some of the inhabitants of the British islands in the West-Indies. It rises with a strait stalk ten or twelve feet high, which is covered with a smooth gray bark, and is sometimes as thick as the small of a man's leg, dividing into several spreading branches at the top, which are armed at each joint with two short, strong, crooked spines, and are garnished with decompound winged leaves, each leaf being composed of six or eight pair of simple winged leaves, the lower pair being composed of four or five pair of lobes, the others gradually increasing in their number toward the top, where they decrease again, and are smaller. The lobes are three quarters of an inch long, and almost half an inch broad at their points, lessening gradually to their base; they are of a light green colour, and when bruised emit a strong odour.

The branches are terminated by loose spikes of flowers, which are sometimes formed into a kind of pyramid, and at others they are disposed more in form of an umbel. The foot-stalk of each flower is near three inches long; the flower is composed of five petals which

which are roundish at the top, but are contracted to narrow tails at their base; they spread open, and are beautifully variegated with a deep red or Orange colour, yellow, and some spots of green; they have a very agreeable odour. In the center of the flower is situated a slender style above three inches long, upon which the germen sits, and is accompanied by ten stamina nearly of the same length with the style, terminated by oblong summits. After the flower is past, the germen becomes a broad flat pod about three inches long, divided into three or four cells by transverse partitions, each including one flattish irregular seed. The leaves of this plant are used instead of Sena in the West-Indies to purge, and in Jamaica the plant is titled Sena.

Ligon says the seeds of this plant were first carried to Barbadoes from Cape Verd Islands, and the beauty of the flowers was such, that the inhabitants soon spread it over that island, and afterward it was transported into most of the neighbouring islands. This may have been so, but it is very certain that the plant grows naturally in Jamaica, where the late Dr. Houstoun found it in the woods at a great distance from any settlements. He also found it growing naturally at La Vera Cruz, and at Campeachy, where he also found the two varieties with red and yellow flowers. The only difference between these and the first sort being in the colour of their flowers, and their branches having fewer spines.

The seeds of this plant are annually brought over in plenty from the West-Indies, which, if sown upon a hot-bed, will rise easily. When the plants are come up, they should be transplanted each into a small pot, and plunged into a hot-bed of tanners bark, observing to shade them from the sun till they have taken root; after which you must give them air in proportion to the warmth of the season; they must be frequently refreshed with water in summer. When the plants have filled the pots with their roots, they should be shaken out, and placed into larger ones, that their roots may have room to spread. If care be taken to water and shift them as often as is necessary, they will grow to be three feet high the first season. At Michaelmas the pots should be plunged into a fresh hot-bed of tanners bark in the stove, which should be kept to the Ananas heat marked on the botanical thermometers, and frequently refreshed with water, but they must not have it in large quantities, which is very injurious to these plants at that season. The earth which these plants should be planted in, must be fresh, light, and sandy (but not over-rich,) in which they will stand the winter better than if planted in a stronger soil. When the plants are grown large, there must be great care taken when they are shifted into larger pots, not to suffer the ball of earth to fall from their roots; for when this happens, the plants seldom survive it.

These plants must constantly remain in the bark-stove, where in warm weather they should have a large share of air, but they must not be exposed to cold; they are very impatient of moisture in winter, and, if damp seizes their top, it very often kills the plants, or at least occasions the loss of their heads. With proper management they will grow much taller here than they usually do in Barbadoes, but their stems will not be larger than a man's finger, which is occasioned by their being drawn up by the glasses of the stove. I have had some of these plants near eighteen feet high in the Chelsea Garden, which have produced their beautiful flowers some years. These flowers have always appeared in December, but in the West-Indies I am informed they flower twice a year, at which times they make a most beautiful appearance.

POKE VIRGINIAN. See PHYTOLACCA.

POLEMONIUM. Tourn. Inst. R. H. 146. tab. 61. Lin. Gen. Plant. 200. [so called, according to Pliny, from *πολεμειν*, Gr. to wage war, on account of the contests which arose betwixt two princes, each assuming the honour of the discovery of it to himself.] Greek Valerian, or Jacob's Ladder.

The CHARACTERS are,

The flower has a permanent empalement of one leaf, which is cut into five segments; it has one petal, of the wheel shape. The tube is very short; the upper part, which is divided, spreads open. It hath five slender stamina which are inserted in the valves of the tube; these are inclined, and are shorter than the petal, and are terminated by roundish summits. In the bottom of the tube is situated an acute oval germen, supporting a slender style which is equal with the petal, crowned by a revolving trifid stigma. The germen afterward turns to a three-celled oval capsule having three cells, filled with irregular acute-pointed seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. POLEMONIUM (*Ceruleum*) calycibus corollæ tubo longioribus. Lin. Sp. Plant. 162. *Greek Valerian, with an empalement longer than the tube of the flower. Polemonium vulgare ceruleum. Tourn. Inst. R. H. 146. Common blue Greek Valerian.*
2. POLEMONIUM (*Reptans*) foliis pinnatis, radicibus reptatricibus. Flor. Virg. 22. *Greek Valerian, with winged leaves and a creeping root.*

The first sort grows naturally in many parts of Europe; it has been discovered growing wild in Carleton Beek, and about Mialham Cove near Craven, in Yorkshire. Of this there are two or three varieties, one with a white, and the other a variegated flower, and another with variegated leaves.

This plant has winged leaves, which are composed of several pair of lobes placed alternately. The lower leaves have eleven or twelve pair, and are terminated by an odd one; these are broadest at their base, ending in points, and sit close to the midrib. The stalks rise near a foot and a half high; they are hollow, channelled, and are garnished with winged leaves of the same form with the lower, but decrease upward in their size, and are terminated by bunches of flowers which sit very close; they have each one petal, which has a short tube, cut into five roundish segments at the top; they are chiefly of a beautiful blue colour, and have each five stamina, which are terminated by yellow summits. These flowers appear the latter end of May, and are succeeded by oval acute-pointed capsules, with three cells filled with irregular seeds, which ripen in August.

These plants are easily propagated by sowing their seeds in the spring upon a bed of light earth, and when they are come up pretty strong, they should be pricked out into another bed of the same light earth about four or five inches asunder, observing to shade and water them until they have taken root; after which they will require no farther care, but to keep them clear from weeds until Michaelmas, at which time they must be transplanted into the borders of the flower-garden, where, being intermixed with different sorts of flowers, they will make a beautiful appearance.

This plant is not naturally of long duration, but by taking them up in autumn and parting of them, they may be continued some years; but as the seedling plants always flower much stronger than the offsets, few persons ever propagate them by slips.

The sort with white flowers will frequently arise from the seeds of the blue, as will also that with variegated flowers, but these may be continued by parting of their roots.

The sort with variegated leaves is preserved by parting of their roots, because the plants raised from seeds would be subject to degenerate and become plain. The best time to part them is about Michaelmas, that they may take good root before the cold weather prevents them. These should have a fresh light soil, but if it be too rich, their roots will rot in winter, or the stripes of the leaves will go off in the summer.

The second sort grows naturally in Virginia and other parts of North America. This hath creeping roots,

by which it multiplies very fast. The leaves have seldom more than three or four pair of lobes, which stand at a much greater distance from each other than those of the common sort; they are of a darker green. The lobes are narrow, and are placed alternately; the stalks rise nine or ten inches high, sending out branches their whole length. The flowers are produced in loose bunches, standing upon pretty long foot-stalks; they are smaller than those of the common sort, and are of a lighter blue colour.

This sort may be propagated by seeds in the same manner as the common sort, or by parting of their roots in autumn, and is equally hardy with the common sort.

POLIANTHES. Lin. Gen. Plant. 384. Hyacinthus. Tourn. Inst. R. H. 344. tab. 180. The Tuberose.

The CHARACTERS are,

The flower has no empalement; it has one petal which is funnel-shaped. The tube is oblong and incurved; the brim is cut into six oval segments which spread open. It hath six thick stamina situated in the chaps of the petal, terminated by linear summits, which are longer than the stamina. In the bottom of the tube is situated a roundish germen, supporting a slender style, crowned by a thick, trifid, honey-bearing stigma. The germen afterward turns to an obtuse, roundish, three-cornered capsule having three cells, which are filled with plain half-round seeds disposed in a double range.

This genus of plants is ranged in the first section of Linnaeus's sixth class, which includes those plants whose flowers have six stamina and one style.

We have but one SPECIES of this genus, viz.

POLIANTHES (*Tuberosa*) floribus alternis. Hort. Cliff. 127. *Polianthes with flowers placed alternately.* Hyacinthus Indicus tuberosus, flore Narcissi. C. B. P. 42. *Tuberous Indian Hyacinth, with a flower like Narcissus, commonly called Tuberose.*

The varieties of this are the Tuberose with a double flower, the striped-leaved Tuberose, and the Tuberose with a smaller flower; the last is mentioned by several authors as a distinct species, but is certainly a variety. Caspar Bauhin titles it Hyacinthus Indicus tuberosus, flore Hyacinthi orientalis. Pin. 47. i. e. Indian tuberous Hyacinth, with a flower like the Eastern Hyacinth. This sort is frequent in the south of France, from whence the roots have been often brought to England early in the spring, before those roots have arrived from Italy, which are annually imported; the stalks of this are weaker, and do not rise so high, and the flowers are smaller than those of the common Tuberose, but in other respects is the same.

The Tuberose grows naturally in India, from whence it was first brought to Europe, where it now thrives in the warmer parts, as well as in its native soil. The Genoese are the people who cultivate this plant, to furnish all the other countries where the roots cannot be propagated without great trouble and care, and from thence the roots are annually sent to England, Holland, and Germany. In most parts of Italy, Sicily, and Spain, the roots thrive and propagate without care, where they are once planted.

This plant has been long cultivated in the English gardens for the exceeding beauty and fragrancy of its flowers; the roots of this are annually brought from Genoa, by the persons who import Orange-trees; for as these roots are too tender to thrive in the full ground in England, so there are few persons who care to take the trouble of nursing up their offsets, till they become blowing roots, because it will be two or three years before they arrive to a proper size for producing flowers; and as they must be protected from the frost in winter, the trouble and expence of covers is greater than the roots are worth; for they are generally sold pretty reasonable, by those who import them from Italy.

The double flowering is a variety of the first, which was obtained from the seed by Monf. Le Cour, of Leyden in Holland, who for many years was so tenacious

of parting with any of the roots, even after he had propagated them in such plenty as to have more than he could plant, so he caused them to be cut in pieces, that he might have the vanity to boast of being the only person in Europe who was possessed of this flower; but of late years the roots have been spread into many parts, and as there is no other method to propagate this but by the offsets, most people who have had of this sort are careful to multiply and increase it; which is done by planting the offsets upon a moderate hot-bed early in March, and covering the bed in cold weather with mats or straw, and in summer they must have plenty of water in dry weather. In this bed the roots may remain till the leaves decay in autumn, but if there should happen any frost before that time, the bed should be covered to guard the roots from the frost, because if the frost enters so low as to reach the roots it will kill them; and if the leaves are injured by the frost, it will weaken the roots. Where there is due care taken to screen them from frost, and too much wet, it will be the best way to let the roots remain in the bed till the end of November or the beginning of December, provided hard frosts do not set in sooner; for the less time the roots are out of the ground, the stronger they will be, and the sooner they will flower; when the roots are taken up, they should be cleaned from the earth, and laid up in dry sand, where they may be secure from frost and wet; here they should remain until the season for planting them again; this same method should be practised by those who are desirous to cultivate the single sort in England, and also that with striped leaves must be propagated the same way.

I shall next give directions for the management of those roots, which are annually brought from Italy. And first, in the choice of the roots, those which are the largest and plumpest, if they are perfectly firm and sound, are the best; and the fewer offsets they have, the stronger they will flower; but the under part of the roots should be particularly examined, because it is there that they first decay; after the roots are chosen, before they are planted, the offsets should be taken off; for if these are left upon the roots, they will draw away part of the nourishment from the old root, whereby the flower-stems will be greatly weakened.

As these roots commonly arrive in England in the month of February or March, those who are desirous to have these early in flower, should make a moderate hot-bed soon after the roots arrive, which should have good rich earth laid upon the dung, about seven or eight inches deep; this bed should be covered with a frame, and when the bed is in a proper temperature for warmth, the roots should be planted at about six inches distance from each other every way. The upper part of the root should not be buried more than one inch in the ground; when the roots are planted, there should be but little water given them until they shoot above ground; for too much wet will rot them, when they are in an inactive state, but afterward they will require plenty of water, especially when the season is warm. When the flower-stems begin to appear, the bed should have a large share of air given to it, otherwise the stalks will draw up weak, and produce but few flowers; for the more air these plants enjoy in good weather, the stronger they will grow, and produce a greater number of flowers; therefore, toward the beginning of May, the frame may be quite taken off the bed, and hoops fastened over it, to support a covering of mats, which need not be laid over but in the night, or in very cold weather, so that by enjoying the free open air their stems will be large; and if they are well watered in dry weather, their flowers will be large, and a great number on each stem.

This first planting will require more care than those which are designed to come after them, for in order to have a succession of these flowers, the roots should be planted at three different times, viz. the first the beginning of March, the second the beginning of April,

April, and the third at the end of that month, or the beginning of May; but these beds will require a much less quantity of dung than the first, especially that bed which is the last made; for if there is but warmth enough to put the roots in motion, it is as much as will be required; and this last bed will need no covering, for many times those roots which are planted in the full ground at this season, will produce strong flowers in autumn; but in order to secure their flowering, it is always the best way to plant them on a gentle hot-bed. As to the second bed, that should be arched over with hoops, and covered with mats every night, and in bad weather, otherwise the late frosts which frequently happen in May will pinch them.

These plants may remain in the beds until the flowers are near expanding, at which time they may be carefully taken up, preserving the earth to their roots, and planted in pots, and then placed in the shade for about a week to recover their removal; after which time the pots may be removed into halls or other apartments, where they will continue in beauty a long time, and their fragrant odour will perfume the air of the rooms where they are placed; and by having a succession of them, they may be continued from Midsummer to the end of October, or middle of November; but as the stems of these plants advance, there should be some sticks put down by each root, to which the stems should be fastened, to prevent their being broken by the wind.

It is a common practice with many people, to plant these roots in pots, and plunge the pots into a hot-bed; but there is much more trouble in raising them in this method, than in that before directed; for if the roots are not planted in very small pots, there will be a necessity of making the beds much larger, in order to contain a quantity of the roots; and if they are first planted in small pots, they should be shaken out of these into pots of a larger size, when they begin to shoot out their flower-stems, otherwise the stalks will be weak, and produce but few flowers; therefore I prefer the other method, as there is no danger in removing the roots if it is done with care.

When the roots are strong and properly managed, the stems will rise three or four feet high, and each stem will produce ten or twelve flowers or more; and in this the great beauty of these flowers consists, for when there are but a few flowers upon the stalks they will soon fade away, so their places must be frequently renewed; for the flowers are produced in spikes coming out alternately upon the stalk, the lower flowers opening first; and as these decay, those above them open, so that in proportion to the number of flowers upon each stalk, they continue in beauty a longer or shorter time.

The sort with double flowers will require a little more care, in order to have the flowers fair; but this care is chiefly at the time of blowing, for the flowers of this sort will not open, if they are exposed to the open air; therefore when the flowers are fully formed and near opening, the pots should be placed in an airy glass-case, or a shelter of glasses should be prepared for them, that the dews and rains may not fall upon them, for that will cause the flowers to rot away before they open, and the heat of the sun drawn through the glasses will cause their flowers to expand very fair. With this management, I have had this sort with very double flowers extremely fair, and upward of twenty upon one stem, so that they have made a beautiful appearance; but where this has not been practised, I have rarely seen one of them in any beauty.

POLIMUM. Tourn. Inst. R. H. 206. tab. 97. Teucrium. Lin. Gen. Plant. 625. Mountain Poley.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, cut into five acute segments. The flower is of the lip kind; it hath one petal, with a short tube. The stamina occupy the place of the upper lip, and the lower lip is cut into five segments. It hath four awl-shaped stamina, which

are terminated by small summits, and a germen divided into four parts, supporting a slender style, crowned by two narrow stigmas; the germen afterwards become four naked seeds, inclosed in the empalement.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, who has joined this genus, and also the Chamædrys and Chamæpitys of Tournefort to the Teucrium, making them but one genus, which includes those plants whose flowers have two long and two shorter stamina, and are succeeded by four seeds in the calyx.

The SPECIES are,

1. POLIUM (*Montanum*) foliis lanceolatis integerrimis, caulibus procumbentibus, floribus corymbosis terminalibus. Mountain Poley with entire spear-shaped leaves, trailing stalks, and flowers growing in a corymbus at the end of the branches. Polium lavendulæ folio. C. B. P. 220. Mountain Poley with a Lavender leaf.
2. POLIUM (*Luteum*) spicis oblongis foliis obtusis crenatis tomentosis. Mountain Poley with oblong spikes of flowers, and obtuse, crenated, woolly leaves. Polium montanum luteum. C. B. P. 220. Yellow Mountain Poley.
3. POLIUM (*Angustifolium*) spicis subrotundis, caulibus suffruticosis incanis, foliis linearibus tomentosis. Mountain Poley with roundish spikes of flowers, hoary shrubby stalks, and very narrow woolly leaves. Polium luteum angustifolium. C. B. P. 220. Narrow-leaved yellow Mountain Poley.
4. POLIUM (*Album*) caule ramoso procumbente, foliis lineari-lanceolatis dentatis, floribus corymbosis terminalibus. Poley with a branching trailing stalk, narrow, spear-shaped, woolly, indented leaves, and flowers growing in a corymbus terminating the branches. Polium montanum album. C. B. P. 221. White Mountain Poley.
5. POLIUM (*Capitatum*) caule erecto diffuso, foliis lineari-lanceolatis crenatis, corymbis terminalibus lateralibusque. Poley with an erect diffused stalk, narrow, spear-shaped, crenated leaves, and flowers growing in a corymbus, terminating and proceeding out of the sides of the branches. Polium maritimum erectum Montpellier. C. B. P. 221. Upright maritime Poley of Montpellier.
6. POLIUM (*Pyreniacum*) caulibus procumbentibus hirsutissimis, foliis cuneiformi-orbiculatis crenatis. Poley with very hairy trailing stalks, and orbicular wedge-shaped leaves which are crenated. Polium Pyreniacum supinum, hederæ terrestris folio. Tourn. Inst. R. H. 206. Low Pyrenean Poley, with a leaf like that of Ground-ivy.
7. POLIUM (*Latifolium*) caule erecto ramoso, foliis lanceolatis dentatis subtus tomentosis, floribus confertis terminalibus. Poley with an upright branching stalk, spear-shaped indented leaves which are woolly on their under side, and flowers growing in clusters terminating the branches. Polium montanum album ferratum, latifolium, erectum majus. Barrel. Obs. 34. Greater upright white Mountain Poley, with a broad sawed leaf.
8. POLIUM (*Erectum*) caule erecto corymboso, foliis linearibus reflexis, floribus terminalibus. Poley with an upright stalk branching out in form of a corymbus, narrow reflexed leaves, and flowers terminating the stalks. Polium montanum album angustifolium. C. B. P. 221. Narrow-leaved white Mountain Poley.
9. POLIUM (*Ramosum*) caule ramoso, procumbente, foliis lineari-lanceolatis supernè dentatis, spicis oblongis terminalibus. Poley with a trailing branching stalk, narrow spear-shaped leaves which are indented toward the top, and oblong spikes of flowers terminating the stalks. Polium Hispanicum supinum, flore flavescente. Tourn. Inst. 207. Low Spanish Poley with a yellowish flower.
10. POLIUM (*Spicatum*) caule erecto suffruticoso, foliis linearibus confertis, spicis cylindricis fastigiatis terminalibus. Poley with an upright under shrub stalk, narrow leaves growing in clusters, and cylindrical spikes of flowers which terminate the stalks. Polium erectum album, angustiori folio & spicâ. Phil. Trans. 417. Upright white Poley with a narrower leaf and spike.

11. POLIUM

11. **POLIUM** (*Fruticosum*) caule erecto fruticoso, foliis lanceolatis tomentosis integerrimis, corymbis terminalibus. *Poley with an upright shrubby stalk, spear-shaped woolly leaves which are entire, and flowers growing in a corymbus terminating the stalks.* Polium Valentinum fruticosum, angustifolium, flore albo. Barr. Icon. 1048. *Shrubby narrow-leaved Poley of Valentia, with a white flower.*
12. **POLIUM** (*Serratum*) caule procumbente, foliis linearibus serratis, corymbis confertis terminalibus. *Poley with a trailing stalk, narrow sawed leaves, and clustered flowers growing in a corymbus at the ends of the stalks.* Polium montanum album, angustifolium serratum, supinum minus. Barrel. Icon. 1091. *Low, smaller, white Mountain Poley, with a narrow sawed leaf.*
13. **POLIUM** (*Diffusum*) caule diffuso procumbente, foliis linearibus dentatis tomentosis, spicis subrotundis. *Poley with a trailing diffused stalk, narrow, indented, woolly leaves, and roundish spikes of flowers.* Polium montanum luteum, serratis angustioribus incanis foliis. Barrel. Icon. 1089. *Yellow Mountain Poley, with narrower, hoary, sawed leaves.*
14. **POLIUM** (*Integerrimum*) caule erecto suffruticoso, foliis lanceolatis integerrimis, corymbis confertis terminalibus. *Poley with an erect shrubby stalk, spear-shaped entire leaves, and clustered flowers growing in a corymbus at the ends of the branches.*
15. **POLIUM** (*Smyræum*) caule diffuso, foliis linearibus pinnato-dentatis, spicis subrotundis lateralibus. *Poley with a diffused stalk, linear, winged, indented leaves, and roundish spikes of flowers proceeding from the sides of the stalks.* Polium Smyræum scordii folio. Tourn. Cor. 14. *Poley of Smyrna, with a Water Germander leaf.*

The first sort grows naturally on the mountains about Basil and Geneva, as also in France. The root of this plant is composed of many ligneous fibres, which spread wide in the ground, from which arise several weak, trailing, ligneous stalks, eight or nine inches long, which send out many small branches, garnished with small spear-shaped leaves, of a deep green and entire; they are placed by pairs. The flowers are produced in a corymbus at the end of the branches; they are white, and shaped like those of the other species. These appear in June and July, but are seldom succeeded by seeds in England. There is another sort with much smaller leaves, which are hoary on their under side, but I am not certain if it is a distinct species.

The second sort grows naturally in Spain; the stalks of this are rather herbaceous, and trail upon the ground; they are about six inches long, hoary, and garnished with woolly leaves about half an inch long; some of them are wedge-shaped, others are oblong, ending in obtuse points, and are crenated toward their ends. The flowers are collected in oblong thick spikes at the end of the branches; they are of a deep yellow colour, and appear the beginning of June, but are seldom succeeded by seeds in this country.

The third sort grows naturally in Spain and Portugal; the stalks of this are ligneous, erect, and branching, covered with a hoary down; they rise six or eight inches high, and are garnished with linear woolly leaves about half an inch long, having sometimes two or three slight indentures on their edges. The flowers are collected in roundish spikes at the end of the branches; they are of a bright yellow, and have woolly empalements. These appear in June and July.

The fourth sort grows naturally in the south of France and in Italy; this hath a trailing branching stalk, which at the bottom is ligneous, but the branches are herbaceous and woolly; they are garnished with linear, spear-shaped, woolly leaves, indented on their edges. The flowers are produced in a corymbus at the end of the branches; they are small, white, and shaped like those of the other species. This flowers in June and July.

The fifth sort grows naturally near the sea, in the south of France and in Italy. This hath an erect branching stalk, which rises a foot high; the lower

part becomes ligneous, but the upper is herbaceous; the leaves are linear, spear-shaped, about an inch long, crenated on their edges, of a pretty thick consistence, and a little woolly. The flowers are collected in a corymbus at the end of the branches; they are white, and like those of the other species. This flowers in July and August.

The sixth sort grows naturally on the Pyrenean Mountains; this hath slender shrubby stalks, which trail close upon the ground; they have a purple bark, and covered with white hairs; the leaves are round at the top, but at their base are contracted in form of a wedge, and are crenated on their edges, so as to resemble at first sight the leaves of Ground-ivy, but they are hairy, and of a thicker consistence. The flowers are collected in round bunches at the end of the branches, one half of their petals are purple, and the other half white; they are larger than those of the other species, but are of the same form. It flowers great part of summer, but seldom produces seeds here.

The seventh sort grows naturally in Italy and Spain; this hath a ligneous, erect, branching stalk, which rises near a foot high; it is very hoary, and branches out toward the top; the leaves are spear-shaped, indented on their edges, and woolly on their under side. The flowers are white, small, and grow in clusters at the end of the branches. It flowers in June and July.

The eighth sort grows naturally in Spain and Italy; this rises with a shrubby stalk nine or ten inches high, branching out toward the top in form of a corymbus; the leaves are linear, and their edges are reflexed. The flowers are collected in roundish woolly heads at the end of the branches; they are white, and smaller than most of the other species. This flowers in June and July.

The ninth sort grows naturally in Spain; it hath a trailing branching stalk about six or eight inches long, which is ligneous at bottom, but upward is herbaceous and hoary; the leaves are linear, spear-shaped, and indented toward the ends. The flowers are collected in oblong spikes at the end of the branches; they are of a pale yellow colour, and shaped like those of the other species. This flowers great part of summer.

The tenth sort grows naturally in Sicily; this hath slender shrubby stalks, which rise a foot and a half high; they are smooth and white, sending out a few short branches toward the top, garnished with small linear leaves growing in clusters. The flowers are collected in long cylindrical spikes, which stand at the top of the stalks, and sometimes come out in bunches on the sides; these are small and white. It flowers in July and August.

The eleventh sort grows naturally in Valencia; this hath slender ligneous stalks near two feet high, which are hoary, and garnished with small, spear-shaped, entire leaves at intervals, standing in clusters; they are woolly, and sit close to the stalk; the upper part of the stalk divides into several slender foot-stalks, each sustaining a small corymbus of white flowers. The whole plant is very hoary, and has a strong aromatic odour; it flowers late in summer.

The twelfth sort grows naturally in the south of France and in Italy; this hath trailing ligneous stalks about a foot long, garnished with linear sawed leaves, which are hoary, and have smaller leaves coming out from the bosom of the other. The flowers are collected in a corymbus at the end of the branches; they are small and white. This flowers in June and July.

The thirteenth sort grows naturally in Spain and Italy; this hath diffused trailing stalks, which are very woolly, about six or seven inches long, garnished with narrow indented leaves, which are covered with a woolly down, and are terminated by roundish heads of flowers, which are yellow; the whole plant is very hoary. It flowers in July.

The fourteenth sort grows naturally in Spain; this hath erect branching stalks about six or eight inches high; the branches come out opposite the whole length of the stalk; they are garnished with small spear-shaped leaves, of a dark green colour on their upper

Acad. p 2. 139.

Teneya. Rattle Snake Root.

G. D. Christ. sculp.

upper side, but hoary on their under; the stalks and branches are terminated by clusters of blue flowers, which are collected in roundish heads. This sort flowers in July and August.

The fifteenth sort grows naturally about Smyrna; this hath diffused stalks, which rise about a foot high; they are white, and closely garnished with linear leaves near two inches long, and about a quarter of an inch broad; they are indented regularly on their edges like those of Spleenwort, but the indentures are not deep; they are of a dark green on their upper side, but hoary on their under. The flowers are collected in roundish spikes, which terminate the branches, and also come out from their side; they are white, and shaped like those of the other species. It flowers in July and August.

There are several other species of this genus, which grow naturally in the warmer parts of Europe; but those which are here mentioned, are all that I have yet seen growing in the English gardens; therefore I have omitted the other, as I have had no opportunity to examine them myself.

All the sorts, except the first, are abiding plants; they may be propagated by seeds, which must be procured from the countries where they naturally grow, because they seldom perfect their seeds in England. These should be sown upon a bed of fresh light earth in the spring, and when the plants come up, they must be carefully kept clean from weeds; about the middle of July the plants will be fit to remove, when they may be carefully taken up, and part of them planted on a warm border of dry rubbishy soil, observing to shade them from the sun, and water them till they have taken new root; after which they will require no other culture but to keep them clean from weeds. My advising these and many other aromatic plants, which are natives of the warmer parts of Europe, to be planted in rubbish, is founded upon long experience of their abiding much longer, and resisting the cold of our winters much better, than when they are growing in better ground, where they grow much freer, are fuller of moisture, and therefore more liable to be killed by frost.

The other part of the plants may be planted in small pots, filled with fresh, light, undunged earth, and placed in the shade till they have taken new root; then they may be removed into an open situation, where they may remain till the beginning of November, when they should be placed under a common frame, to secure them from the frost in winter, which sometimes destroys these plants; by this method the species may be preserved.

These plants may be disposed in a garden, so as to afford pleasure, by mixing them with Marum, Mastich, and several other aromatic plants, upon the sloping sides of banks, which are exposed to the sun, or upon little hillocks raised in a sheltered situation, where, by the diversity of their hoary branches, being of various shapes, they will make a pretty appearance; and in such places they will resist the cold much better, than when they are planted in a good soil.

They may also be propagated by cuttings or slips, which should be planted the beginning of April, just before they shoot, upon a border exposed to the East; and if the season proves dry, they must be watered and shaded until they have taken root, and afterward they will require no other care but to keep them clean from weeds, and at Michaelmas the plants should be removed where they are designed to remain; but it will be proper to put a plant of each sort in pots, that they may be sheltered in winter to preserve the kinds. The fourth and fifth sorts are sometimes used in medicine.

POLYANTHUS. See PRIMULA.

POLYGALA. Tourn. Inst. R. H. 174. tab. 79. Lin. Gen. Plant. 761. [This plant is so called, of *γάλα*, much, and *γάλα*, milk, because if cattle are fed in marshes that produce this plant, they give a great quantity of milk; it is also called Ambarvalis, of Ambicndis Arvis, from lustrating the fields; because

the ancients used to crown virgins with the flowers of this plant, when they perambulated the fields, to implore fertility thereto; it is also called Amarella, because it has a bitter taste.] Milkwort.

The CHARACTERS are,

The flower has a small permanent empalement of three leaves, which are oval and acute; two of these are below the petals, and one is above. The flower is shaped like those of the butterfly kind, the number of petals is indeterminate. The wings are large, plain, and extend beyond the other petals; the standard is tubulous, short, and reflexed at the brim, where it is bifid. The keel is concave, compressed, and belled toward the top. It hath eight stamina in two bodies, included in the keel, terminated by single summits; and an oblong germen supporting an erect style, terminated by a thick bifid stigma. The germen afterward becomes a heart-shaped capsule having two cells, each containing one seed.

This genus of plants is ranged in the second section of Linnæus's seventeenth class, which contains those plants whose flowers have eight stamina joined in two bodies.

The SPECIES are,

1. POLYGALA (*Vulgaris*) floribus cristatis racemosis, caulibus herbaceis simplicibus procumbentibus, foliis lineari-lanceolatis. Amœn. Acad. 2. p. 136. *Milkwort with branching crested flowers, single, trailing, herbaceous stalks, and linear spear-shaped leaves. Polygala vulgaris. C. B. P. 215. Common Milkwort.*
2. POLYGALA (*Monspeliaca*) floribus cristatis, racemosis, caule erecto, foliis lanceolato-linearibus acutis. Sauv. Monsp. 53. *Milkwort with branching crested flowers, an erect stalk, and acute, spear-shaped, linear leaves. Polygala vulgaris coloris obsoleti, foliis angustissimis. J. B. 3. p. 338. Common Milkwort with a worn-out flower, and the narrowest leaves.*
3. POLYGALA (*Myrtifolia*) floribus cristatis, carinâ lunulata, caule fruticoso, foliis lævibus oblongis obtusis. Amœn. Acad. 2. p. 138. *Milkwort with crested flowers, a moon-shaped keel, and a shrubby stalk bearing oblong leaves, which end in obtuse points. Polygala frutescens, folio buxi, flore maximo. Tourn. Inst. 175. Shrubby Milkwort, with a Box-tree leaf and a large flower.*
4. POLYGALA (*Chamaebuxus*) floribus imberbibus sparsis, carinæ apice subrotundo, caule fruticoso, foliis lanceolatis. Amœn. Acad. 2. p. 140. *Milkwort with flowers growing thinly and without beards, the point of the keel roundish, a shrubby stalk, and spear-shaped leaves. Chamaebuxus flore coluteæ. C. B. P. 471. Low Box with a flower like Bladder Sena.*
5. POLYGALA (*Senega*) floribus imberbibus spicatis, caule erecto herbaceo simplicissimo, foliis lato-lanceolatis. Amœn. Acad. 2. p. 139. *Milkwort with spiked flowers having no beards, an erect, single, herbaceous stalk, and broad spear-shaped leaves. Polygala Virginiana, foliis oblongis, floribus in thyrsis candidis, radice alexipharmicâ. Edit. Prior. Milkwort of Virginia with oblong leaves, white flowers ranged in a loose spike, and an alexipharmic root, commonly called Senega Rattle Snakeroot.*
6. POLYGALA (*Mariana*) floribus imberbibus, oblongo-capitatis, caule erecto ramoso, foliis linearibus. *Milkwort with beardless flowers growing in oblong heads, an erect branching stalk, and linear leaves. Polygala Mariana, angustiori folio, flore purpureo. Pluk. Mantiss. 153. tab. 438. fig. 5. Maryland Milkwort with a narrower leaf and a purple flower.*
7. POLYGALA (*Americana*) floribus cristatis, racemo terminali, caule erecto ramoso, foliis lanceolatis tomentosis. *Milkwort with crested flowers, an erect branching stalk, terminated by a loose spike of flowers, and woolly spear-shaped leaves. Polygala Americana erecta, flore purpureo-cæruleo, folio molli incano. Houst. MSS. Upright American Milkwort, with a purplish blue flower and a soft hoary leaf.*

There are several other species of this genus, some of which grow naturally in Europe, and others in America, but as they are seldom cultivated in gardens, it would be to little purpose to enumerate them here.

The first sort grows naturally in pastures, and upon heaths in many parts of England; of this there are three varieties, one with a blue, another with a purple, and a third with white flowers, which are frequently found intermixed; and there is another which is larger, and supposed to be a distinct species; but I rather believe this difference is owing to the soil in which they grow; for the large one is generally found growing in moist pastures, and the small one upon dry heaths. This hath a perennial root, from which come out three or four slender, trailing, herbaceous stalks, about six inches long, garnished with linear spear-shaped leaves, about half an inch long, and an eighth part of an inch broad in the middle, terminating in points at both ends. The flowers are produced at the top of the stalks, branching out; they are small, and of a blue, purple, or white colour, having two wings, a keel and standard like the butterfly flowers. These appear in June, and are succeeded by flattish heart-shaped capsules, divided into two cells, each containing one seed.

The second sort grows naturally upon sterile ground about Montpellier; this sort is annual; it rises with an upright stalk about six inches high, which is garnished with narrow leaves placed alternate, ending in acute points. The flowers are small, of a worn-out purple colour; the keel is bearded like the common sort. This flowers in July, and has seed-vessels like the first sort, but smaller; the seeds ripen in autumn.

These sorts are very rarely admitted into gardens, nor do they thrive so well when sown or transplanted there, as in their natural situation. If these are cultivated, their seeds should be sown soon after they are ripe, otherwise they rarely grow.

The third sort grows naturally at the Cape of Good Hope; this hath a shrubby stalk, covered with a smooth brown bark, which rises four or five feet high, sending out several spreading branches toward the top, which are closely garnished with oblong, blunt-pointed, smooth leaves, about an inch long, and a quarter of an inch broad, of a lucid green, sitting close to the branches. The flowers are produced at the end of the branches; they are large, white on their outside, but of a bright purple within; the keel of the flower is hollowed like a half-moon, and is bearded; the wings are expanded wide, and the standard is incurved; this plant continueth flowering most part of summer. The flowers are succeeded by compressed heart-shaped seed-vessels, having two cells, each containing one hard, smooth, shining seed. This plant is propagated by seeds, which should be sown in small pots, filled with light loamy earth; soon after they are ripe, these pots may be placed where they may have the morning sun only till October, when they should be placed under a hot-bed frame, and plunged into old tanners bark, which has lost its heat, where they may be defended from frost during the winter, and in the spring the pots should be plunged into a moderate hot-bed, which will bring up the plants. When these appear, they should not be too tenderly treated, but must have a large share of free air admitted to them; when they are fit to transplant, they should be carefully shaken out of the pots, and separated, planting each into a small pot filled with soft loamy earth, and plunged into a very moderate hot-bed to forward their taking new root, observing to shade them from the sun, and gently refresh them with water as they may require it, but they must not have too much wet. When they are rooted, they must be gradually inured to the open air, and in June they may be placed abroad in a sheltered situation, where they may remain till the middle or latter end of October, according as the season proves favourable; then they must be removed into the green-house, and treated in the same way as Orange-trees, being careful not to give them too much wet during the winter season. In the summer they must be placed abroad with other green-house plants, where, by their long continuance in flower, they will make a fine appear-

ance. The management of this plant is nearly the same as for the Orange-tree.

The fourth sort grows naturally on the Alps, and also upon the mountains in Austria and Hungary; this rises with a slender, branching, ligneous stalk about a foot high, when it grows upon good ground, but on a rocky soil seldom more than half that height. The branches are closely garnished with stiff, smooth, spear-shaped leaves of a lucid green. From between the leaves, toward the top of the branches, the flowers come out upon very short foot-stalks; they are white on their outside, but within are of a purplish colour mixed with yellow, and have a grateful odour. These appear in May, and are succeeded by seed-vessels shaped like those of the former sort.

This plant is very difficult to cultivate in gardens, for it commonly grows out of the fissures of rocks, so cannot be easily transplanted, and the seeds are with difficulty obtained from abroad; nor do these vegetate till they have been a whole year in the ground, unless they are sown soon after they are ripe, when the plants will come up the spring following; when the plants first come up, they make very little progress here, and are as difficult to transplant as almost any plant at present known, which occasions its present scarcity in England.

The best method of cultivating this is by seeds, which should be procured as fresh as possible from the places of its natural growth, and sown in pots as soon as it arrives; the pots may be plunged into the ground, where they may have only the morning sun. If these are sown before Christmas, there will be a chance of the plants coming up the following spring; but those which are not sown till toward spring, will remain in the ground a year; therefore the pots should be plunged into the ground, where they may have but little sun the following summer, and in autumn they may be removed, and plunged into an old tan-bed under a hot-bed frame, where they may be protected from severe frost; for although this plant is a native of the Alps and other cold mountains, yet as the seeds will not be covered with snow here, as they are in their native soil and situation, they are frequently spoiled here by the inconstancy of the weather in England. When the plants come up, they should be placed in shade during summer; and in autumn they may be turned out of the pots, and planted in a border where they may have only the morning sun, for this plant will not thrive long in pots. If the winter proves very severe, it will be proper to cover the surface of the ground about their roots with mulch to keep out the frost. If the plants take root in the border, they should remain there undisturbed, and be only kept clean from weeds, for the ground about their roots should not be dug or dunged.

The fifth sort grows naturally in most parts of North America. This hath a perennial root composed of several fleshy fibres, from which arise three or four branching stalks, which grow erect, and are more than a foot high; these are garnished with spear-shaped leaves placed alternately. The flowers are produced in loose spikes at the end of the branches; they are small, white, and shaped like those of the common sort, but their keels have no beards. It flowers here in July, but the plants do not produce seeds here.

The root of this sort hath been long used by the Seneka Indians to cure the bite of the rattle-snake, which, if taken in time, is an infallible remedy. And of late years it has been used by the inhabitants of Virginia in many disorders, which are occasioned by a thick sily blood; so that the root of this plant, when its virtues are fully known, may become one of the most useful medicines yet discovered. The Seneka Indians use this root, which they powder, and generally carry about them when they travel in the woods, lest they should be bit by the rattle-snake; and whenever this happens, they take a quantity of the powder inwardly, and apply some of it to the part bitten, which is a sure remedy.

The

P O L

The sixth sort grows naturally in Maryland; this hath a perennial root, from which arise two or three stalks about eight inches high, which divide into several erect branches, garnished with small linear leaves of a dark green colour. The flowers are collected into oblong heads at the end of the stalks; they are small, and of a purplish blue colour.

Both these sorts are difficult to obtain, for the seeds rarely succeed, so the best way is to procure their roots from America, and when they arrive plant them in a bed of light earth in a sheltered situation. In summer they must be kept clean from weeds, and if the surface of the ground about their roots is covered with old tanners bark, or any other kind of mulch in winter, to keep out the frost, it will be a secure method to preserve them.

The seventh sort was discovered by the late Dr. Houstoun growing naturally at La Vera Cruz: this hath a taper perennial root which runs deep in the ground, from which arise several slender branching stalks about six or seven inches high, garnished with downy spear-shaped leaves an inch long, and half an inch broad in the middle, drawing to a point at both ends. The flowers are produced in loose spikes at the end of the branches; they are larger than those of the common sort, and are of a bluish purple colour. The keel of the flower is bearded, as in the common sort.

This is too tender to live in the open air in England, and it is one of those plants which will not thrive in pots, so is difficult to preserve here. It is propagated by seeds, which must be procured from abroad. The seeds, which I received from Dr. Houstoun, remained a year in the ground before the plants appeared, and the plants lived one year; but when their roots reached the bottom of the pots, they decayed; and those which were transplanted into larger pots did not survive their removal, though it was performed with great care.

POLYGONATUM. See CONVALLARIA.

POLYMNIA. Lin. Gen. 987. Hard-seeded Chrysanthemum.

The CHARACTERS are,

The flower hath a double empalement; the outer is composed of five large spreading leaves, the inner of ten erect spear-shaped leaves; it hath a radiated flower, whose disk is composed of hermaphrodite florets, and the border, or rays, of five female half florets, which are tongue-shaped and trifid. The hermaphrodite florets are funnel-shaped, have each five stamina terminated by cylindrical summits, which are longer than the petals; they have a small germen, supporting a slender style, crowned by an obtuse stigma; these are barren. The female half florets have a large germen, with a slender style the length of the tube, crowned by two pointed stigmas; these have each one oval gibbous seed lodged in the scaly receptacle, succeeding them.

This genus of plants is ranged in the fourth section of Linnæus's nineteenth class, intitled Syngenesia Polygamia necessaria, the plants having hermaphrodite and female florets; the former having five stamina whose summits are connected, the latter are fruitful.

The SPECIES are,

1. **POLYMNIA** (*Uvedalia*) foliis oppositis hastato-sinuatis. Lin. Sp. 1303. Hard-seeded Chrysanthemum, with sinuated leaves placed opposite. Chrysanthemum angulosum platani foliis Virginianum. Pluk. Phyt. tab. 83. f. 3.
2. **POLYMNIA** (*Canadensis*) foliis alternis hastato-sinuatis. Lin. Sp. 1303. Hard-seeded Chrysanthemum, with sinuated leaves placed alternate.

The first sort grows naturally in Virginia, from whence I have received the seeds; this hath a perennial root, which runs deep in the ground, sending up in the spring many stalks in proportion to their size; these in moist good ground will rise near ten feet high, and are garnished with large, angular, sinuated leaves eight or ten inches over, of a light green, placed opposite; the stalks are terminated by a cluster of yellow flowers sitting close, having very short foot-stalks; each having five female half florets in their borders,

P O M

and several hermaphrodite florets in their middle, which are encompassed by a double empalement, the outer having five spreading leaves, the inner ten erect ones; the flowers appear in October, which is too late to be succeeded by seeds in England; the stalks decay in winter, and new ones arise in the spring.

The second sort grows naturally in several parts of North America; this has also an abiding root, which sends up many tall stalks in the spring, which rise almost as high as those of the other sort; these are garnished with large, angular, sinuated leaves, of a deeper green than those of the former, which are placed alternately; the flowers are of a paler yellow colour, and sit close on the top of the stalks; these appear late in the autumn, so are not succeeded by seeds in England.

These plants are both propagated by seeds, which must be procured from the countries where the plants grow naturally, so that the seeds seldom arrive here till toward the spring; and being sown at that season, the plants seldom come up until the following spring; whereas, if the seeds could be obtained in November, and were immediately sown, the plants would appear the following spring, whereby a year would be saved. The seeds should be sown in a bed of light ground in the open air; and when the plants come up, they should be thinned if they are too close, and kept clean from weeds till the following autumn, when the roots should be carefully taken up, and transplanted to the places where they are to remain, allowing each plant at least three feet room to grow, observing to keep them clean from weeds, and to dig the ground about them every spring.

POLYPODIUM. Tourn Inst. R. H. 540. tab. 316.

Lin. Gen. Plant. [of πολὺς many, and ποὺς a foot, q. d. many feet. This kind of plant strikes its roots into every part it can lay hold of, whether it be stone, earth, or tree, it is the same thing, especially if it be a tree of the Oak kind.] Polypody.

The CHARACTERS are,

This is one of the Fern tribe, which is distinguished from the others, by the fructification being in roundish spots, distributed on the under surface of the leaf.

It is ranged in the first section of Tournefort's sixteenth class, which includes the herbs, which have no visible flower, whose fruit is fastened on the leaves.

The SPECIES are,

1. **POLYPODIUM** (*Vulgare*) frondibus pinnatifidis, pinnis oblongis subserratis obtusis, radice squamata. Lin. Sp. Plant. 1085. Polypody with wing-pointed leaves having oblong obtuse lobes, which are somewhat sawed, and a scaly root. Polypodium vulgare. C. B. P. 359. Common Polypody.
2. **POLYPODIUM** (*Cambricum*) frondibus pinnatifidis, pinnis lanceolatis lacero-pinnatifidis serratis. Lin. Sp. Plant. 1086. Polypody with wing-pointed leaves, whose lobes are spear-shaped, and the jags wing-pointed and sawed. Polypodium Cambro-Britannicum, pinnulis ad margines laciniatis. Raii Syn. Welsh Polypody with jagged leaves.

There are many other species of this plant which are natives of America, some of which are preserved in the curious botanic gardens for variety; but as they are rarely cultivated in other gardens, it may not be thought necessary to enumerate them in this place.

The first sort is that which is used in medicine, and is found growing upon old walls and shady banks in divers parts of England. The second sort was brought from Wales, where it grows in great plenty, and is the most beautiful of all the sorts. These plants may be propagated by parting of their roots in the spring before they shoot, and should be planted in a very poor moist soil under the shade of a wall; for if they are exposed to the sun, they will not thrive. They chiefly delight to grow out of the joints of walls and old buildings, but are commonly found exposed to the North.

POMUM ADAMI. See AURANTIUM.

P O N.

P O N

PONTEDERIA. Lin. Gen. Plant. 391. Michelia. Houtt. MSS.

The CHARACTERS are,

The flowers are included in an oblong sheath, which opens on one side, and hath six petals, which are divided; the three upper are erect, and form a kind of lip; the three under are reflexed. It hath six stamina which are inserted to the petals; the three which are longest, are fastened to the mouth of the tube, the other are inserted in the base; they are terminated by prostrate summits. Under the petals is situated an oblong germen, supporting a single style which declines, and is crowned by a single stigma. The germen afterward turns to a soft fruit divided into six cells, each containing several small roundish seeds.

This genus of plants is ranged in the first section of Linnæus's sixth class, which includes the plants whose flowers have six stamina and one style.

The SPECIES are,

1. **PONTEDERIA** (*Cordata*) foliis cordatis, floribus spicatis. *Pontederia* with heart-shaped leaves and spiked flowers. *Sagittæ similis planta palustris Virginiana*, spicâ florum cæruleâ. Mor. Hist. 3. p. 618. *Virginian marsh plant, like Arrow-head, having a spike of blue flowers.*

2. **PONTEDERIA** (*Hastata*) foliis hastatis, floribus umbellatis. Lin. Sp. Plant. 412. *Pontederia* with spear-pointed leaves, and flowers growing in umbels. *Sagittariæ quodammodo similis planta Maderaspataua*, floribus medio caule quasi ex utriculo prodeuntibus. Pluk. Phyt. tab. 220. *A plant from Madras, somewhat like Arrow-head, with flowers proceeding from the middle of the stalk.*

The first sort grows naturally in marshy places in Virginia, and most parts of North America, and the late Dr. Houstoun found it growing plentifully at La Vera Cruz. This hath a perennial root, from which arise two or three herbaceous thick stalks a foot high, each having one heart-shaped leaf about five inches long, and two and a half broad, of a pretty thick consistence. The base is deeply indented, and the two ears are rounded; the foot-stalk of the leaf closely embraces the stalk like a spatha or sheath, for near three inches in length; above this is another sheath which incloses the spike of flowers; this opens on one side, and the stalk rises near two inches above it, where the spike of flowers begin. The spikes are about three inches long; the flowers are blue, sit very close together, and have the appearance of lip flowers. These appear in June, but are not succeeded by seeds in England.

As this plant grows naturally in moist boggy places, it is very difficult to be preserved in England; nor does the plant arise from seeds here, for I have sowed the seeds in various situations, and managed them different, but could never get up any of the plants; but I had three or four of the plants sent me, inclosed in large clods of earth from New England, which I planted in pots, covering them with Moss, and constantly supplied them with water. With this management two of them flowered, but the following winter destroyed them, as they were not put under shelter; so that to preserve them, they should be placed under a hot-bed frame in winter, where they may be exposed to the open air at all times when the weather is mild.

The second sort grows naturally about Madras in watery places. This rises with a single stalk eight or nine inches high, having one arrow-pointed leaf, whose base embraces the stalk like a sheath, and from the open side of the sheath comes out the flowers, which are at first inclosed in another smaller sheath; these grow in a small kind of umbel; they are composed of six acute-pointed petals which spread open. Each flower stands upon a slender foot-stalk about an inch long; the foot stalk of the leaf rises a considerable height above the flowers, so that they appear to come out from the middle of the stalk.

This sort is much more difficult to preserve in England, because it grows naturally in a hot country, and always in places flowed with water. There was for-

P O P

merly one of these plants brought over to Charles Duboise, Esq; at Mitcham, but it was not long-lived here.

POPULAGO. See CALTHA.

POPULUS. Tourn. Inst. R. H. 592, tab. 365. Lin. Gen. Plant. 996. The Poplar-tree; in French, *Peuplier*.

The CHARACTERS are,

The male and female flowers grow upon separate trees. The male flowers or katkins have one oblong, loose, cylindrical empalement, which is imbricated. Under each scale, which is oblong, plain, and cut on the border, is situated a single flower without any petal, having a nectarium of one leaf, turbinate at the bottom, and tubulous at the top, and eight stamina terminated by large four-cornered summits. The female flowers are in katkins like the male, but have no stamina; they have an oval acute-pointed germen, with scarce any style, crowned by a four-pointed stigma. The germen afterward becomes an oval capsule with two cells, including many oval seeds having hairy down.

This genus of plants is ranged in the seventh section of Linnæus's twenty-second class, which contains those plants whose male flowers have eight stamina, and grow upon distinct plants from the fruit.

The SPECIES are,

1. **POPULUS** (*Alba*) foliis subrotundis dentato-angulatis subtus tomentosis. Hort. Cliff. 460. *Poplar-tree with roundish angular leaves, which are downy on their under side.* *Populus alba majoribus foliis.* C. B. P. 429. *White Poplar with larger leaves, commonly called the Abele-tree.*
2. **POPULUS** (*Tremula*) foliis subrotundis, dentato-angulatis utrinque glabris. Hort. Cliff. 460. *Poplar-tree with roundish leaves, which are angularly indented, and smooth on both sides.* *Populus tremula.* C. B. P. 429.
3. **POPULUS** (*Nigra*) foliis deltoidibus acuminatis serratis. Hort. Cliff. 460. *Poplar with pointed sawed leaves, shaped like the Delta.* *Populus nigra.* C. B. P. 429. *Black Poplar.*
4. **POPULUS** (*Major*) foliis angulatis serratis, subtus tomentosis supernè virentibus. *Poplar with larger angular sawed leaves, downy on their under side, and dark green on their upper.* *Populus alba majoribus foliis.* C. B. P. 429. *Greater white Poplar, or Abele-tree.*
5. **POPULUS** (*Balsamifera*) foliis subcordatis oblongis crenatis. Hort. Cliff. 460. *Poplar-tree with oblong leaves which are crenated, and almost heart-shaped.* *Populus nigra folio maximo, gemmis balsamum odoratissimum fundentibus.* Catesb. Carolin. 1. p. 34. *The Carolina Poplar-tree.*
6. **POPULUS** (*Tacamahacca*) foliis subcordatis, infernè incanis, supernè atroviridis. *Poplar with leaves which are almost heart-shaped, hoary on their under side, and of a dark green above.* *Populo similis arbor resinosa altera.* C. B. P. 430. *Another resinous tree like the Poplar, commonly called Tacamahacca.*

The first sort grows naturally in the temperate parts of Europe; this and the fourth sort are frequently confounded together, but they are certainly different species. The fourth sort is commonly called Abele-tree here, and the first white Poplar. The leaves of the fourth sort are large, and divided into three, four, or five lobes, which are indented on their edges; they are of a very dark colour on their upper side, and very white and downy on their under, standing upon foot-stalks which are about an inch long. The young branches of this tree have a purple bark, and are covered with a white down, but the bark of the stem and older branches is gray. In the beginning of April the male flowers or katkins appear, which are cylindrical, scaly, and three inches long, and about a week after come out the female flowers on katkins, which have no stamina like those of the male. Soon after these come out, the male katkins fall off, and in five or six weeks after, the female flowers will have ripe seeds inclosed in a hairy covering, when the katkins will drop, and the seeds will be wafted by the winds to a great distance.

The

The leaves of the first sort are rounder, and not much above half the size of those of the fourth; they are indented on their edges into angles, and are downy on their under side, nor are their under surfaces of so dark green. The shoots of this are paler, the katkins are longer, and the down of the seeds is whiter and longer.

The leaves of the third sort are oval, heart-shaped, and slightly crenated on their edges; they are smooth on both sides, and of a light green colour. The katkins of this are shorter than those of the two former.

The fifth sort grows naturally in Carolina, where it becomes a very large tree. The shoots of this sort are very strong in England, and are generally cornered; they have a light green bark like some sorts of the Willow. The leaves upon young trees, and also those upon the lower shoots, are very large, almost heart-shaped, and crenated, but those upon the older trees are smaller; and as the trees advance, their bark becomes lighter, approaching to a grayish colour. The katkins of this sort are like those of the black Poplar, and the summits of the stamina are purple.

The shoots of this tree while young, are frequently killed down a considerable length by the frost in winter; but as the trees grow older, their shoots are not so vigorous, and become more ligneous, so are not liable to the same disaster; but the trees should be planted in a sheltered situation, for as their leaves are very large, the wind has great power over them, and the branches being tender, they are frequently broken or split down by the winds in the summer season, where they are much exposed.

The sixth sort grows naturally in Canada, and in other parts of North America; this seems to be a tree of middling growth, and does not spire upward, but sends out many short thick shoots on every side, which are covered with a light brown bark, and garnished with leaves differing from each other in shape and size, most of them almost heart-shaped, but some are oval, and others near to spear-shaped; they are whitish on their under side, but of a dark green on their upper. The katkins are like those of the black Poplar, but the number of stamina in the male flowers is uncertain, from eighteen to twenty-two. The female flowers I have not fully examined, but by the male katkins I have been induced to place it in this genus.

These trees may be propagated either by layers or cuttings, which will readily take root, as also from suckers, which the white Poplars send up from their roots in great plenty; but these are less valuable than those propagated by cuttings, being more liable to send up suckers. The best time for transplanting these suckers is in October, when their leaves begin to decay. These may be placed in a nursery for two or three years to get strength, before they are planted out where they are designed to remain; but if you intend to propagate them from cuttings, it is better to defer the doing of that until February, at which time you may plant truncheons of two or three feet long, thrusting them about a foot and a half into the ground. These will readily take root, and if the soil be moist in which they are planted, they will arrive to a considerable bulk in a few years.

The black Poplar is not so apt to take root from large truncheons, therefore it is the better method to plant cuttings about a foot and a half in length, thrusting them a foot deep into the ground; these will take root very freely, and may be afterward transplanted where they are to remain. This sort will grow upon almost any soil, but will thrive best in moist places.

I have planted cuttings of this tree, which in four years have been bigger in the trunk than a man's thigh, and near twenty feet in height, and this upon a very indifferent soil; but in a very moist soil, it is common for these trees to shoot eight or ten feet in a season; so that where a person hath a mind to make a shelter in a few years, there is scarce any tree so proper for that purpose as this; but they should not be plant-

ed too near the pleasure-garden, because the katkins and down which fall from these trees, will make a prodigious litter in the spring.

The white sorts, as also the Aspen-tree, likewise cause a greater litter in the spring, when their katkins and down fall off; and their roots being very apt to produce a large quantity of suckers, but especially those trees that came from suckers, which renders them unfit to be planted near a house or garden; but when they are interspersed with other trees in large plantations, they afford an agreeable variety, their leaves being very white on their under sides, which, when blown with the wind, are turned to sight.

A considerable advantage may be made by planting these trees upon moist boggy soils, where few other trees will thrive. Many such places there are in England, which do not at present bring in much money to their owners; whereas, if they were planted with these trees, they would, in a very few years, over purchase the ground, clear of all expence; but there are many persons, who think nothing except Corn worth cultivating in England; or if they plant timber, it must be Oak, Ash, or Elm; and if their land be not proper for either of these, it is deemed little worth; whereas if the nature of the soil was examined, and proper sorts of plants adapted to it, there might be very great advantage made of several large tracts of land, which at this time lie neglected.

The wood of these trees, especially of the Abele, is very good to lay for floors, where it will last many years; and for its exceeding whiteness, is by many persons preferred to Oak; but being of a soft contexture, is very subject to take the impression of nails, &c. which renders it less proper for this purpose: it is also very proper for wainscoting of rooms, being less subject to swell or shrink, than most other sorts of wood; but for turnery ware, there is no wood equal to this for its exceeding whiteness, so that trays, bowls, and many other utensils, are made of it; and the bellows-makers prefer it for their use, as do also the shoemakers, not only for heels, but also for the soles of shoes; it is also very good to make light carts, and the poles are very proper to support Vines, Hops, &c. and the lopping will afford good fuel, which in many countries is much wanted.

The Carolina Poplar may also be propagated by cuttings or layers; the latter is generally practised by the nursery gardeners, being the surest method; and these plants are not so full of moisture as those raised by cuttings, so are less liable to be cut down by the frost when young. There has been no trials made here of the wood of this tree, so I cannot give any account of its worth.

The Tacamahacca sends up a great number of suckers from the roots, by which it multiplies in plenty, and every cutting which is planted will take root; so that when a plant is once obtained, there may soon be plenty of the plants raised. The buds of this tree are covered with a glutinous resin, which smells very strong, and this is the Tacamahacca used in the shops.

PORRUM. Tourn. Inst. R. H. 382. tab. 204. Allium. Lin. Gen. Plant. 370. [in Greek is called *ωπάριον*, from *ωπάω*, to enkindle, as being a plant that excites a warmth in the body.] Leek.

The CHARACTERS are,

The flower hath six bell-shaped petals, which are collected into a spherical head, covered by a common roundish spathe or sheath, which opens on one side, and withers. These have six stamina, three of which are alternately broader than the other, and have forked summits in their middle. They have a short, round, three-cornered germen, supporting a single style, crowned by an acute stigma. The germen afterward becomes a short broad capsule with three lobes, having three cells filled with angular seeds.

This genus of plants is joined to Linnæus's genus of Allium, which is ranged in the first section of his sixth class, including the plants whose flowers have six stamina and one style. The joining of these genera together is allowable in a system of botany, but

in a treatise upon gardening, it would not so well please; for as the Leek has always been distinguished from Garlick and Onion by gardeners, so it would rather confuse than instruct the practitioners, if they were joined; and as the species of Garlick are numerous, so where their species are lessened, by dividing them into genera, it will be no less useful to botanists.

The SPECIES are,

1. PORRUM (*Sativum*) radice oblongâ tunicatâ, caule planifolio, floribus capitatis, staminibus tricuspидatis. *Leek with an oblong coated root, a plain leaf on the stalk, flowers collected in heads, and three-pointed stamina.* Porrum commune capitatum. C. B. P. 72. *Common-headed Leek, commonly called London Leek.*

2. PORRUM (*Ampeloprasum*) caule planifolio umbellifero, umbellâ globosâ, staminibus corolla longioribus. *Leek with a plain leaf on the stalk, which supports a globular umbel of flowers, whose stamina are longer than the petals.* Porrum Siberiense, floribus purpurascens. Gmel. *Siberian Leek having purplish flowers.*

The first sort is commonly cultivated in the English gardens; of this there has been generally supposed two sorts, but I have made trial of them both, by sowing their seeds several times, and find they are the same; the difference which has risen between them, has been occasioned by some persons having saved the seeds from old roots, and not from the seedling Leeks, whereby they have degenerated them, and rendered them smaller and narrower leaved; but by care this may be recovered again, as I have experienced.

The other sort grows naturally in Siberia; this hath narrower leaves than the common sort, the stalks are smaller, and do not rise so high; the heads of flowers are also smaller, and of a purplish colour; the stamina stand out beyond the flower.

Leeks are cultivated by sowing their seeds in the spring, in the same manner as was directed for Onions, with which these are commonly sown, the two sorts of seeds being mixed according to the proportion which is desired of either sort; though the most common method is, to mix an equal quantity of both, for the Onions will greatly out-grow the Leeks in the spring; but these being drawn off early in August, the Leeks will have time to grow large afterwards, so that there may be a moderate crop of both sorts. The management of Leeks being exactly the same with Onions, I shall not repeat it in this place; but shall only add, that many persons sow their Leeks very thick in beds in the spring; and in June, after some of their early crops are taken off, they dig up the ground, and plant their Leeks out thereon, in rows a foot apart, and six inches asunder in the rows, observing to water them until they have taken root; after which they will require no further culture, but to clear the ground from weeds. The Leeks thus planted will grow to a moderate size, provided the ground be good, and this method is very proper for such persons who have little room.

If you would save the seeds of this plant, you should make choice of some of the largest and best Leeks you have, which must remain in the place where they grew until February, when they should be transplanted in a row against a warm hedge, pale, or wall, at about eight inches asunder; and when their stems advance, they should be supported by a string, to prevent their being broken down, to which they are very liable, especially when in head; and the closer they are drawn to the fence in autumn, the better the seeds will ripen; for it sometimes happens in cold summers or autumns, that those which grow in the open garden, do not perfect their seeds in this country, especially if there should be sharp frosts early in autumn, which will entirely spoil the seed.

When it is ripe (which may be known by the heads changing brown) you should cut off their heads with about a foot or more of the stalk to each, and tie them in bundles, three or four heads in each, and hang them up in a dry place, where they may remain till

Christmas or after, when you may thresh out the seeds for use. The husk of these seeds is very tough, which renders it very difficult to get out the seeds; therefore some persons who have but a small quantity, rub it hard against a rough tile, which will break the husks, and get the seeds out better than most other methods I have known used.

PORTULACA. Tourn. Inst. R. H. 236. tab. 118. Lin. Gen. Plant. 531. Purslane; in French, *Pourpier*.

The CHARACTERS are,

The empalement of the flower is small, bifid, and permanent, sitting upon the germen. The flower has five plain, erect, obtuse petals, and many hair-like stamina, about half the length of the petals, terminated by single summits; and a roundish germen, supporting a short style, crowned by five oblong stigmas. The germen afterward becomes an oval capsule with one cell, containing many small seeds.

This genus of plants is ranged in the first section of Linnæus's eleventh class, which contains the plants whose flowers have from eleven to nineteen stamina inclusive, and one style.

The SPECIES are,

1. PORTULACA (*Oleracea*) foliis cuneiformibus, floribus sessilibus. Prod. Leyd. 473. *Purslane with wedge-shaped leaves, and flowers growing close to the stalks.* Portulaca latifolia seu sativa. C. B. P. 288. *Broad-leaved, or Garden Purslane.*

2. PORTULACA (*Pilosa*) foliis subulatis alternis, axillis pilosis, floribus sessilibus terminalibus. Lin. Sp. Plant. 445. *Purslane with awl-shaped leaves placed alternately, hairy joints, and flowers sitting close to the stalks.* Portulaca Curassavica angusto longo lucidoque folio, procumbens. Hort. Amst. 1. p. 2. *Trailing Purslane of Curasso, with long, narrow, shining leaves.*

3. PORTULACA (*Anacampseros*) foliis ovatis gibbis, pedunculo multifloro, caule fruticoso. Lin. Sp. Plant. 445. *Purslane with oval gibbous leaves, foot-stalks having many flowers, and a shrubby stalk.* Telephiastrum folio globoso. Hort. Elth. 376. *Bastard Orpine with a globular leaf.*

The first sort grows naturally in America, and most of the hot parts of the globe. This is the common Purslane which is cultivated in the gardens, and is so generally known as to need no description. There are two varieties of this, one with deep green leaves, and the other hath yellow leaves, which is called Golden Purslane; but as both these arise from the same seeds, so they are only seminal variations. There is also a third variety with smaller and less succulent leaves, which is called wild Purslane, because wherever it is once sown in a garden, and the plants permitted to scatter seeds, the plants will come up as weeds the following year; but this I am sure is a degeneracy from the Garden Purslane, for I have sown it several times and let the plants shed their seeds, and it has come up from those seeds in two years, degenerated to the wild sort.

Purslane is propagated from seeds, which may be sown upon beds of light rich earth during any of the summer months; but if you intend to have it early in the season, it should be sown upon a hot-bed; for it is too tender to be sown in the open air before April, and then it must be in a warm situation. This seed is very small, so that little of it will be sufficient to supply a family. There is no other culture which this plant requires, but to keep it clear from weeds, and in dry weather to water it two or three times a week. In warm weather this plant will be fit for use in six weeks after sowing, so that in order to continue a succession of it, you should sow it at three or four different seasons, allowing a fortnight or three weeks between each sowing, which will be sufficient to last the summer, so long as it is proper to be eaten; for being of a very cold nature, it is unsafe to be eaten, except in the heat of summer in England; for which reason, it is not to any purpose to sow it upon a hot-bed, since it will come early enough for use in the open air.

If

If the seeds are intended to be saved, a sufficient number of the earliest plants should be left for this purpose, drawing out all those which are weak, or have small leaves, from among them; and when the seeds are ripe, the plants should be cut up, and spread upon cloths in the sun to dry, and then the seeds may be easily beaten out and sifted, to clear it from the leaves and seed-vessels.

The second sort grows naturally in most of the islands of the West Indies; this is annual; the stalks are very succulent, of a purple colour, and branch out greatly; the lower branches lie near the ground, but those above them are more erect; the leaves are narrow, awl-shaped, and of a lucid green; they are placed alternately on the branches. At the joints there come out tufts of white hairs, and between these come out the flowers sitting close to the branches; they are of a fine Pink colour, but of short duration, seldom continuing open longer than five or six hours; these are succeeded by short roundish capsules, filled with small black seeds. It flowers from the middle of June till autumn.

The third sort grows naturally at the Cape of Good Hope; this is a perennial plant with a shrubby stalk, which rises four or five inches high, garnished with thick, globular, succulent leaves; at the top of the stalk comes forth a slender foot-stalk about two inches long, sustaining four or five Rose-shaped flowers of a red colour. These appear in July, but are not succeeded by seeds in England. This plant is too tender to live in the open air in winter, so it must be kept in pots, and treated in the same way as the most succulent kinds of Aloes. It is propagated by cuttings.

POTENTILLA. Lin. Gen. Plant. 559. Quinquefolium pentaphylloides. Tourn. Inst. R. H. 296. tab. 153, 298. Cinquefoil; in French, *Quinte-feuille*.

The CHARACTERS are,

The empalement of the flower is of one leaf, which is slightly cut into ten parts; the segments are alternately left and reflexed. The flower is composed of five petals, which are inserted into the empalement, and spread open. It hath twenty awl-shaped stamina inserted in the empalement, terminated by moon-shaped summits. In the center of the flower there are several germen collected into one head, with very slender styles inserted in the side of the germen, crowned by obtuse stigmas. After the flower is past, the germen becomes a head of roundish seeds, included in the empalement.

This genus of plants is ranged in the fifth section of Linnæus's twelfth class, which includes those plants whose flowers have about twenty stamina inserted in the empalement, and have many germen.

The SPECIES are,

1. POTENTILLA (*Anserina*) foliis pinnatis serratis, caule repente. Flor. Lapp. 210. *Potentilla with winged sawed leaves, and a creeping stalk.* Pentaphylloides argenteum alatum, seu potentilla. Tourn. Inst. 298. *Silver Weed, or Wild Tanfy.*
2. POTENTILLA (*Rupensis*) foliis pinnatis alternis, foliolis quinis ovatis crenatis, caule erecto. Hort. Cliff. 193. *Potentilla with alternate winged leaves, having five oval crenated lobes, and an erect stalk.* Pentaphylloides erectum. J. B. 2. p. 398. *Upright Cinquefoil.*
3. POTENTILLA (*Fruticosa*) foliis pinnatis, caule fruticoso. Hort. Cliff. 193. *Potentilla with winged leaves and a shrubby stalk.* Pentaphylloides rectum fruticosum Eboracense. Mor. Hist. 2. 193. *Upright shrubby Cinquefoil of Yorkshire, commonly called shrubby Cinquefoil.*
4. POTENTILLA (*Rezia*) foliis septenatis lanceolatis serratis utrinque subpilosis, caule erecto. Lin. Sp. Plant. 711. *Potentilla with seven spear-shaped, sawed, hairy leaves, and an erect stalk.* Quinquefolium erectum luteum. C. B. P. 325. *Yellow upright Cinquefoil.*
5. POTENTILLA (*Argentea*) foliis quinatis cuneiformibus incisus subtus tomentosis, caule erecto. Lin. Sp. Plant. 497. *Potentilla with five wedge-shaped cut leaves, which are woolly on their under side, and have an erect stalk.*

Quinquefolium folio argenteo. C. B. P. 325. *Cinquefoil with a silvery leaf.*

6. POTENTILLA (*Caulescens*) foliis quinatis apice conniventis serratis, caulibus multifloris erectis; receptaculis hirsutis. Hort. Cliff. 194. *Potentilla with five leaves whose points are sawed, erect stalks with many flowers, and hairy receptacles.* Quinquefolium album minus alterum. C. B. P. 325. *Another smaller white Cinquefoil.*
7. POTENTILLA (*Monspeliensis*) foliis ternatis, caule ramoso erecto, pedunculis supra genicula enatis. Hort. Upsal. 134. *Potentilla with leaves growing by threes, an upright branching stalk, and foot-stalks rising above the joints.* Fragaria sterilis Alpina caulescens. Boerh. Ind. alt. 1. p. 42. *Stalky Alpine barren Strawberry.*
8. POTENTILLA (*Grandiflora*) foliis ternatis, dentatis utrinque subpilosis, caule decumbente foliis longiore. Lin. Sp. Plant. 715. *Potentilla with three hairy leaves, and a trailing stalk longer than the leaves.* Fragaria sterilis amplissimo folio & flore, petalis cordatis. Vaill. Paris. 55. tab. 10.
9. POTENTILLA (*Heptaphylla*) foliis septenis quinatisque, foliolis pinnato-incisis pilosis, caule erecto ramoso. *Potentilla with seven and five leaves, whose lobes are cut, winged, and hairy, and an upright branching stalk.* Quinquefolium quod pentaphyllum seu potius heptaphyllum rectum, caule rubro hirsutis. Hort. Cath. *Cinquefoil or Septfoil, with a red, upright, hairy stalk.*

There are many more species of this genus, which are preserved in botanic gardens for the sake of variety, but as they are not cultivated in other places either for use or beauty, I shall not enumerate them here.

The first sort here mentioned, grows naturally upon cold stiff land in most parts of England, and is a sure mark of the sterility of the soil. It spreads its stalks upon the ground, which send out roots from their joints, fastening into the ground, and thereby propagates so fast, as in a little time to spread over and fill the ground to a great distance. The leaves are composed of several lobes (or wings) which are generally placed alternately along the midrib, and terminated by an odd one; they are sawed on their edges, and are of a silvery colour, especially on their under side. The flowers are produced singly upon very long foot-stalks, which arise from the root; they are composed of five yellow petals, which expand in form of a Rose; these have a great number of stamina which are inserted to the petals, and many germen collected in heads, which afterward become many acute-pointed seeds wrapped up in the empalement. It flowers great part of summer. The leaves of this plant are used in medicine; and are accounted restraining and vulnerary. It is rarely cultivated in gardens, being a very common weed in England.

The second sort grows naturally on the Alps, and mountains in Germany. This hath a perennial root, which sends out several heads joined together; from these arise the foot-stalks of the leaves, which are long, and sustain three pair of roundish lobes, terminated by an odd one; these are crenated on their edges, and sit close to the midrib. Out of each head arises a hairy stalk about nine inches high, having at each joint one or two trifoliate leaves, shaped like those below, but smaller; the upper part of the stalk divides into small foot-stalks, each sustaining two or three white flowers, very like those of the Strawberry. These appear in June, and are succeeded by seeds like those of the former. It is easily propagated by seeds, or parting of the roots; the best time of sowing the seeds is in the autumn, and that is also the season for parting and transplanting the roots; it loves a moist soil and a shady situation.

The third sort grows naturally in the northern counties of England, and in many of the northern parts of Europe. This hath a shrubby stalk, which rises about four feet high, dividing into many branches, which are garnished by winged leaves, composed of

two or three pair of narrow, acute-pointed, entire lobes, which are hairy, and pale on their under side. The flowers are produced at the end of the branches in clusters; they have five yellow petals spreading open in form of a Rose, with many germen and stamina within. These appear in July, and are sometimes succeeded by seeds inclosed in the empalement. This plant is commonly cultivated in the nursery-gardens as a flowering shrub, by suckers, or laying down the tender branches, which will take root in one year, and may then be taken off from the old plants, and planted in a nursery for a year or two to get strength, before they are planted where they are designed to remain. It may also be propagated by cuttings, which may be planted in autumn in a moist shady border, where they will take root the next spring, and the Michaelmas following may be transplanted into the nursery.

The best season for transplanting of these plants is in October, that they may get new roots before the hard frost sets in; for as this plant grows naturally upon moist boggy land, so when it is removed in the spring, if due care is not taken to water it in dry weather, it is apt to miscarry; nor will this plant live in a hot dry soil, but in a shady situation and on a cool moist soil it will thrive exceedingly.

The fourth sort grows naturally in the south of France and Italy; this hath hand-shaped leaves, composed of five or seven lobes which join at their base, where they meet the foot-stalk; they are deeply crenated on their sides, and are hairy on both sides. The stalks rise nine or ten inches high, branching toward the top, and garnished at each joint with one leaf, of the same form as those below, but smaller. The flowers grow at the top of the stalk; they are white, and shaped like those of the former sort, appearing about the same time, and are succeeded by seeds like those. This is a biennial plant, which dies soon after the seeds are ripe. It may be propagated as the second sort.

The fifth sort grows naturally on the Alps, and in other rough hilly parts of Europe. This hath a thick fleshy root which strikes deep in the ground, from which arise several purple branching stalks about a foot high, garnished with leaves composed of five wedge-shaped lobes, which are deeply cut on their edges, and are very hoary on their under side. The flowers grow at the top of the stalk, which branches out into many foot-stalks; they are yellow, and shaped like those of the fourth sort, but smaller. The root is perennial, and the plant may be propagated as the second sort.

The sixth sort grows on the mountains in Austria; this hath a perennial root; the leaves stand upon foot-stalks which arise from the root, and are very long; they are composed of five oblong lobes which are a little sawed at their ends, very hoary and silky on their under sides, but green on their upper. The flowers are produced upon long slender foot-stalks, which arise immediately from the root; they are white, and shaped like those of the other species, appearing in May, but are seldom succeeded by seeds in England. It may be easily propagated by runners in the same manner as the Strawberry; the best time to transplant them is in autumn. It loves a cool soil and a shady situation.

The seventh sort grows naturally near Montpellier; this is a perennial plant; the stalks grow erect, about a foot high; they are very hairy, and garnished with trifoliate oblong leaves, sawed on their edges. The flowers are produced upon foot-stalks, which come out above the joints of the stalk; they are white, and large. This plant flowers in June, and the seeds ripen in autumn, which, if permitted to scatter, will produce plants in plenty the following spring, which will require no other culture but to keep them clean from weeds.

The eighth sort is also a perennial plant, but differs from the other in having trailing stalks; the lobes of the leaves are oval, obtuse, and bluntly indented

on their edges; the flowers are larger, and the whole plant is of a deeper green. It flowers in July, and the seeds ripen in autumn. It propagates itself like the former sort.

The ninth sort grows naturally in Italy and Sicily; this is a perennial plant; the stalks rise near two feet high, they are purple and very hairy, garnished with leaves composed of five or seven narrow lobes, which are deeply cut on their sides, so as to resemble those of winged leaves; the stalks branch out greatly toward their top. The flowers are yellow, and shaped like those of the fourth sort. It flowers in June, and the seeds ripen in autumn. It may be propagated as the fourth sort.

POTERIUM. Lin. Gen. Plant. 948. Pimpinella. Tourn. Inst. R. H. 156. tab. 68. Burnet; in French, *Pimprenelle*.

The CHARACTERS are,

It hath male and female flowers in the same spike. The male flowers have a three-leaved empalement; they have one petal, which is cut into four parts; these are oval, concave, and permanent, and a great number of long hair-like stamina, terminated by roundish twin summits. The female flowers have one wheel-shaped petal with a short tube, cut at the brim into four parts; these have no stamina, but two oblong oval germen, with two hairy styles the length of the petal, crowned by coloured pencil-shaped stigmas. The germen afterward becomes two hard seeds, inclosed in the petal of the flower.

This genus of plants is ranged in the eighth section of Linnæus's twenty-first class, which includes those plants whose flowers are male and female in the same spike, and the male flowers have many stamina.

The SPECIES are,

1. POTERIUM (*Sanguisorba*) inermis, caulibus subangulosis. Hort. Cliff. 446. *Unarmed Poterium with angular stalks.* Pimpinella sanguisorba minor hirsuta. C. B. P. 160. *Smaller hairy Burnet.*
2. POTERIUM (*Hybridum*) inermis, caulibus teretibus strictis. Lin. Sp. Plant. 994. *Unarmed Poterium with a narrow taper stalk.* Pimpinella agrimonoides odorata. H. R. Par. *Sweet-smelling Burnet resembling Agrimony.*
3. POTERIUM (*Spinosum*) spinis ramosis. Hort. Cliff. 445. *Poterium with branching spines.* Pimpinella spinosa, seu sempervirens. Mor. Umb. 57. *Prickly or evergreen Burnet.*

The first sort is the common Burnet, which grows naturally upon chalky lands in many parts of England; of this there are two or three varieties, one of them is much smoother than the other, and the third hath larger seeds than either of the former; but these differences are not constant, being only feminal variations. This is a perennial plant, from whose root arise a great number of leaves, standing on pretty long foot-stalks; they are composed of five or six pair of lobes, terminated by an odd one. The lobes are generally ranged a little alternate on the midrib, but sometimes stand by pairs; they are sawed on their edges, and are sometimes smooth, and at others hairy. The stalks rise a foot and a half high, branching out pretty much, and are terminated by long slender foot-stalks, each sustaining an oblong spike of flowers, in which there are some male and others female; they are of a purplish red colour, and appear in June. The female flowers are each succeeded by two hard seeds, which ripen in autumn.

This plant is propagated in gardens; the young tender leaves are put into sallads in winter and spring, and the leaves are used for cool tankards in hot weather. It is used in medicine, and is reckoned to be cordial and alexipharmic. The powder of the root is commended against spitting of blood.

This plant is easily propagated by seeds, which should be sown in autumn soon after they are ripe; for if it is sown in spring, the seeds frequently lie in the ground till the spring following. If the seeds are permitted to scatter, the plants will come up in plenty; and if these are transplanted out in a bed of undunged earth, at about a foot distance every way, and kept

clean

clean from weeds, they will continue some years, especially if the soil is dry, and will require no other care. It may also be propagated by parting the roots in autumn; but as the plants arise so freely from scattered seeds, the latter method is seldom practised. This plant has been of late recommended by persons of little skill, to be sown as a winter pabulum for cattle; but whoever will give themselves the trouble to examine the grounds where it naturally grows, will find the plants left uneaten by the cattle, when the Grass about them has been cropped to the roots; beside, in wet winters and on strong land, the plants are of short duration, therefore very unfit for the purpose, nor is the produce sufficient to tempt any persons of skill to engage in its culture; therefore I wish those persons to make trials of it in small quantities, before they embark largely in these new schemes.

The second sort grows naturally in the south of France and Italy; this is a biennial plant, which decays soon after the seeds are ripe. The leaves of this are like those of Agrimony, and are composed of three or four pair of oblong lobes, placed a little alternate on the midrib, and terminated by an odd one: they are deeply sawed on their edges, and have an agreeable scent; the stalks rise two feet high, and are garnished at each joint with one of those winged leaves, which gradually diminish in their size at the top, and just above the leaf arises a long foot-stalk, which supports two or three small ones, each sustaining a small roundish spike of flowers. These appear in July, and are succeeded by seeds which ripen in autumn. It is propagated by seeds, which, if sown in autumn, the plants will come up the following spring. These require no other culture than to thin them where they are too close, and keep them clean from weeds; the second year they will flower and ripen their seeds, and soon after decay.

The third sort grows naturally in Crete, and in many of the islands of the Archipelago. This hath a shrubby perennial stalk, which rises about three feet high, dividing into several slender branches, which are armed with branching sharp thorns; the leaves are very small; they are winged, and have six or seven pair of very small lobes, ranged opposite along the midrib, terminated by an odd one; they are of a lucid green, and continue all the year. The flowers are produced in small heads at the end of the branches, and are of an herbaceous colour; they appear the beginning of June, and there is a succession of them most part of summer; but those only which come early, are sometimes succeeded by seeds in England.

This plant is too tender to live through the winter in the open air; but if it is sheltered under a common hot-bed frame in winter, where it may have the free air at all times when the weather is mild, and sheltered from hard frost, it will thrive better than when it is more tenderly treated. It may be propagated by slips or cuttings during any of the summer months, which, if planted in a bed of light earth, and covered down close with a hand or bell-glass, and shaded from the sun, will take root and may then be taken up, and planted each into a separate small pot, filled with fresh undunged earth, and placed in the shade till they have taken new root, and then removed to a sheltered situation, where they may stand till the frost comes on, when they should be placed under the hot-bed frame. It requires but little water, especially in cool weather, and wants no particular culture.

PRASIUM. Lin. Gen. Plant. 655. Galeopsis. Tourn. Inst. R. H. 186. Shrubby Hedge-nettle.

The CHARACTERS are,

The flower hath a bell-shaped empalement of one leaf, divided into two lips; the upper lip is broad, and ends in three acute points; the lower lip is cut into two parts. The flower is of the lip kind; it hath one petal; the upper lip is oval, erect, and indented at the end. The lower lip is broad, reflexed, and ends in three points, the middle one being broadest. It has four awl shaped stamina under the upper lip, two of which are shorter than the other, having oblong summits on their side, and a four-

pointed germen sustaining a slender style the length of the stamina, crowned by a bifid stigma. The germen afterward become four berries, each containing a single roundish seed.

This genus of plants is ranged in the first section of Linnæus's fourteenth class, which includes those plants whose flowers have two long and two shorter stamina, and the seeds are naked.

The SPECIES are,

1. PRASIUM (*Majus*) foliis ovato-oblongis serratis. Lin. Hort. Cliff. 309. *Shrubby stinking Hedge-nettle, with oblong, oval, sawed leaves. Galeopsis Hispanica frutescens, teucii folio. Tourn. Inst. 186. Spanish, shrubby, stinking Hedge-nettle, with a Tree Germander leaf.*
2. PRASIUM (*Minus*) foliis ovatis duplici utrinque crenatis. Lin. Hort. Cliff. 309. *Shrubby stinking Hedge-nettle, with oval leaves which are indented on every side. Lamium fruticans, teucii folio lucido, calyce & flore magno candido: tantillâ purpurâ variè notato. Hort. Cath. 106. Shrubby Dead-nettle, with a lucid Tree Germander leaf, and a large white flower with some spots of purple.*

The first sort grows naturally in Spain and Italy; this rises with a shrubby stalk two feet high, covered with a whitish bark, and divides into many branches, which are garnished with oblong oval leaves, sawed on their edges. The flowers come out from the bosom of the leaves in whorls round the stalks; they are white, and have large permanent empalements, cut into five points. The flowers are of the lip kind; they appear in June and July, and are succeeded by four small berries sitting in the empalement, which turn black when they are ripe, and have a single roundish seed in each.

The second sort grows naturally in Sicily; this hath a shrubby stalk like the former, but rises a little higher; the bark is whiter, the leaves are shorter and oval, and are doubly crenated on each side; they are of a lucid green. The flowers come out in small whorls from the bosom of the leaves, like the former; they are somewhat larger, and are frequently marked with a few purple spots; these are succeeded by small berries like the other sort, which ripen at the same time. These plants may be propagated either by cuttings, or from the seeds: if they are propagated by cuttings, they should be planted on a shady border toward the end of April; but the cuttings should not be taken from such plants as have been drawn weak, but rather from those which have been exposed to the open air, whose shoots are short and strong; and if a joint of the former year's wood is cut to each of them, they will more certainly succeed. These cuttings may remain in the same border till they are well rooted, when they may be transplanted into the places where they are to remain, or into pots, that they may be sheltered in winter under a common frame, where they may have as much free air as possible in dry weather, but only require to be screened from hard frost. If they are propagated by seeds (which the plants produce in plenty every year) they should be sown on a bed of light earth in April; and in May the plants will come up, when they require no other care but that of keeping them clean from weeds; and in the autumn following, they may be transplanted in the same manner as before directed for those raised from cuttings, and may be afterward treated more hardily, as they acquire strength.

A plant or two of each of these species may be allowed to have a place where there are collections of the different sorts of ever-green shrubs, for the sake of variety; especially where the different sorts of Cistus, Phlomis, Tree-wormwood, and Medicago, are admitted, because these are equally hardy; and when a severe winter happens, which destroys the one, the others are sure of the same fate; but in mild winters they will live abroad, especially if they are planted in a dry rubbishy soil, and have a sheltered situation; but in rich wet ground, the plants will grow vigorous in summer, so are liable to injury from the early frosts in autumn.

PRENANTHES. Lin. Gen. Plant. 816. Vaill. Mem. ann. 1721. Wild Lettuce.

The CHARACTERS are,

It hath a smooth cylindrical empalement spreading at the brim, having many scales, which are equal, but have three at the base unequal. This common empalement includes from five to eight hermaphrodite florets, disposed in a single round order; they have one petal, which is stretched out like a tongue, and indented in four parts at the end; they have five short hair-like stamina, terminated by cylindrical summits. The germen is situated under the petal, supporting a slender style longer than the stamina, crowned by a bifid reflexed stigma. The germen afterward becomes a single heart-shaped seed, crowned with hairy down.

This genus of plants is ranged in the first section of Linnæus's nineteenth class, which includes the plants with a flower composed of all hermaphrodite or fruitful florets, whose stamina and style are connected.

The SPECIES are,

1. **PRENANTHES** (*Muralis*) flosculis quinis, foliis runcinatis. Hort. Cliff. 383. *Prenanthes with five florets and spear-shaped leaves. Lactuca sylvestris murorum, flore luteo. J. B. 2. p. 1004. Wild Wall Lettuce with a yellow flower.*
2. **PRENANTHES** (*Purpurea*) flosculis quinis, foliis lanceolatis denticulatis. Hort. Cliff. 383. *Prenanthes with five florets, and spear-shaped indented leaves. Lactuca montana purpuro-cæruleo major. C. B. P. 123. Greater purple, blue, Mountain Lettuce.*
3. **PRENANTHES** (*Altissima*) flosculis quinis foliis trilobis, caule erecto. Lin. Sp. Plant. 797. *Upright Prenanthes with five florets, and leaves having three lobes. Prenanthes Canadensis altissima, foliis variis, flore luteo. Vaill. Act. 1721. Tallest Prenanthes of Canada, with variable leaves and a yellowish flower.*
4. **PRENANTHES** (*Amplexicaule*) flosculis quinis, caule ramoso foliis ovato-lanceolatis semiamplexicaulibus. *Prenanthes with five florets, a branching stalk, and oval spear-shaped leaves half embracing the stalk. Lactuca montana, purpuro-cærulea minor. C. B. P. 143. Smaller purple, blue, Mountain Lettuce.*

The first sort grows naturally upon walls and dry shady banks in many parts of England, so is never cultivated in gardens. The second sort grows naturally upon the Helvetian Mountains; this hath a creeping root, which spreads far in the ground, so becomes a troublesome weed if admitted into gardens. The stalks of this rise four feet high; the leaves are spear-shaped, and a little indented toward their ends; the flowers are of a purple blue colour, and are produced loose in panicles from the sides, and at the top of the stalks. These appear in July, and are succeeded by seeds which ripen in autumn.

The third sort grows naturally in most parts of North America, where it is called Dr. Witt's Rattle-snake root; this seldom lives longer than two years. The lower leaves are four or five inches long, and three broad; they are sometimes divided into five lobes, but generally into three; they are indented a little on their edges, smooth, of a dark green on their upper side, but pale on their under. The stalks rise three feet high, and are garnished with a few small leaves which are entire; the flowers come out from the side of the stalk in small bunches; these are of a pale yellow colour, and appear in July. They are succeeded by seeds, crowned with hairy down, which ripen in autumn. There is a variety of this with pale purple flowers which arise from the same seeds. The roots of these plants are said to be an antidote to expel the venom of the rattle-snake, which induced me to mention these plants.

The fourth sort grows naturally on the mountains in Germany; this hath a perennial root. The stalks rise a foot high, and branch out on each side; the leaves are spear-shaped and oval; their base is broad, and half surrounds the stalk; the flowers grow loosely upon slender foot-stalks, which come out from the side, and at the end of the branches. These appear in June, and the seeds ripen in autumn.

These plants are seldom admitted into gardens, but if any person is desirous to cultivate them, if they sow the seeds soon after they are ripe, in a sheltered situation, the plants will come up, and require no other care but to keep them clean from weeds.

PRIMULA. Lin. Gen. Plant. 180. *Primula veris.* Tourn. Inst. R. H. 124. tab. 47. [This plant is so called, because it is the first plant that appears in the spring.] The Primrose; in French, *Primevere*.

The CHARACTERS are,

The flower hath a five-cornered tubulous empalement of one leaf, ending in five acute points; it hath one petal, with a cylindrical tube the length of the empalement, but spreads open above, where it is cut into five heart-shaped segments. It has five short stamina situated in the neck of the petal, terminated by erect acute-pointed summits, and a globular germen supporting a slender style, crowned by a globular stigma. The germen afterward turns to an oblong capsule with one cell, opening at the top, filled with small angular seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. **PRIMULA** (*Veris*) foliis dentatis rugosis, pedunculis unifloris. *Primrose with rough indented leaves, and foot-stalks bearing one flower. Primula veris odorata, flore luteo simplic. J. B. 3. p. 495. Sweet-smelling Primrose with a single yellow flower, or common Primrose.*
2. **PRIMULA** (*Elatior*) foliis dentatis rugosis, floribus fastigiatis. *Primrose with rough indented leaves, and flowers growing in bunches. Primula veris pallido flore elatior. Clus. Hist. 301. Taller Primrose with a pale flower, called Cowslip.*
3. **PRIMULA** (*Farinosa*) foliis crenatis glabris, florum limbo plano. Hort. Cliff. 50. *Primrose with smooth crenated leaves, and a plain border to the flower. Primula veris rubro flore. Clus. Hist. 300. Primrose with a red flower, called Bird's-eye.*
4. **PRIMULA** (*Polyantha*) foliis petiolatis subcordatis crenatis, floribus fastigiatis pedunculis longissimis. *Primrose or Cowslip with heart-shaped crenated leaves having foot-stalks, and flowers growing in bunches on very long foot-stalks.*

The first sort of Primrose grows wild in woods, and other shady places in most parts of England, from whence their roots may be easily transplanted into the garden, where, if they are placed under hedges, and in shady walks, they make a beautiful appearance early in the spring, when few other plants are in flower.

This plant is so well known as to need no description; the flowers and roots of this are used in medicine.

There are several varieties of this which have been accidentally obtained, as the paper-white Primrose with single and double flowers, the common Primrose with double flowers, the red Primrose with single and double flowers; these have but one flower upon a foot-stalk.

The second sort is the Cowslip, or Paigle, or Paralysis of the shops; this grows naturally in meadows and moist pastures in many parts of England. The flowers of this sort grow in bunches at the top of the stalk, so are easily distinguished from the former; they are much used in medicine, and sometimes the leaves. As these grow wild, their roots may be taken up and transplanted into gardens.

The best time to transplant them is at Michaelmas, that their roots may have strength to produce their flowers early in the spring. These delight in a strong soil, but will grow in almost any sort of earth, provided they have a shady situation.

There are a great variety of this at present in the gardens, as the Hose in Hose, the double Cowslip, and all the sorts of Polyanthus, which have been so much improved within the last fifty years, as to almost equal the variety of the Auriculas; and in some parts of England they are so much esteemed as to sell for a guinea a root, so that there may be still a much greater

P R I

greater variety raised, as there are so many persons engaged in the culture of this flower.

The several varieties of Polyanthus are produced by sowing of seeds, which should be saved from such flowers as have large upright stems, producing many flowers upon a stalk, which are large, beautifully striped, open flat, and not pin-eyed. From the seeds of such flowers there is room to hope for a great variety of good sorts, but there should be no ordinary flowers stand near them, lest, by the mixture of their farina, the seeds should be degenerated.

These seeds should be sown in boxes filled with light rich earth in December, being very careful not to bury the seed too deep; for if it be only slightly covered with light earth, it will be sufficient. These boxes should be placed where they may have the benefit of the morning sun until ten of the clock, but must by no means be exposed to the heat of the day, especially when the plants begin to appear; for at that time, one whole day's sun will entirely destroy them. In the spring, if the season should prove dry, you must often refresh them with water, which should be given very moderately; and, as the heat increases, you should remove the boxes more in the shade, for the heat is very injurious to them.

By the middle of May these plants will be strong enough to plant out, at which time you should prepare some shady borders which should be made rich with neats dung, upon which you must set the plants about four inches asunder every way, observing to water them until they have taken root; after which they will require no farther care but to keep them clear from weeds, until the latter end of August following, when you should prepare some borders which are exposed to the east, with good light rich earth, into which you must transplant your Polyanthus, placing them six inches asunder equally in rows, observing, if the season proves dry, to water them until they have taken root; in these borders your plants will flower the succeeding spring, at which time you must observe to mark such of them as are fine to preserve, and the rest may be transplanted into wildernesses, and other shady places in the garden, where, although they are not very valuable flowers, they will afford an agreeable variety.

Those which you intend to preserve, may be removed soon after they have done flowering (provided you do not intend to save seeds from them), and may be then transplanted into a fresh border of the like rich earth, allowing them the same distance as before, observing also to water them until they have taken root; after which they will require no farther care, but only to keep them clear from weeds, and the following spring they will produce strong flowers, as their roots will be then in full vigour; so that if the kinds are good, they will be little inferior to a shew of Auriculas. These roots should be constantly removed and parted every year, and the earth of the border changed, otherwise they will degenerate, and lose the greatest part of their beauty.

If you intend to save seeds, which is the method to obtain a great variety, you must mark such of them, which, as I said before, have good properties. These should be, if possible, separated from all ordinary flowers, for if they stand surrounded with plain-colored flowers, they will impregnate each other, whereby the seeds of the valuable flowers will not be near so good, as if the plants had been in a separate border, where no ordinary flowers grew; therefore the best way is to take out the roots of such as you do not esteem as soon as the flowers open, and plant them in another place, that there may be none left in the border, but such as you would chuse for seeds. The flowers of these should not be gathered, except such as are produced singly upon pedicles, leaving all such as grow in large bunches; and if the season should prove dry, you must now and then refresh them with water, which will cause their seed to be larger, and in greater quantity, than if they were

P R O

entirely neglected. In June the seed will be ripe, which may be easily known by the pods changing brown and opening; so that you should at that time look over the plants three or four times a week, gathering each time such of the seed-vessels as are ripe, which should be laid upon a paper to dry, and may then be put up until the season of sowing.

As the plants which arise from seeds, generally flower much better than offsets, those who would have these flowers in perfection, should annually sow their seeds.

PRIMROSE-TREE. See ONAGRA.

PRINOS. Lin. Gen. Plant. 398. Winterberry.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is cut into six small plain segments, and is permanent; it hath one wheel-shaped petal with no tube, cut into six plain segments; it hath six awl-shaped stamina shorter than the petal, terminated by obtuse summits, and an oval germen sitting upon the style, crowned by an obtuse stigma. The germen afterward turns to a round berry opening in three parts, including one hard seed.

This genus of plants is ranged in the first section of Linnæus's sixth class, which includes those plants whose flowers have six stamina and one style.

The SPECIES are,

1. PRINOS (*Verticillatus*) foliis longitudinaliter serratis. Lin. Sp. Plant. 330. *Prinos, or Winterberry, with leaves sawed lengthways.*

2. PRINOS (*Glaber*) foliis apice serratis. Lin. Sp. Plant. 330. *Prinos with leaves sawed at their points.*

The first sort grows naturally in Virginia, and other parts of North America. This rises with a shrubby stalk to the height of eight or ten feet, sending out many branches from the sides the whole length, which are garnished with spear-shaped leaves about three inches long, and one broad in the middle, terminating in acute points; they are of a deep green, veined on their under side, and sawed on their edges, having slender foot-stalks standing alternately on the branches. The flowers come out from the side of the branches, sometimes single, at others two or three at each joint; they have no tube, but are wheel-shaped, and cut into six parts; they have six awl-shaped erect stamina, terminated by obtuse summits, and an oval germen sitting upon the style, crowned by an obtuse stigma; these are succeeded by berries about the size of those of Holly, which turn purple when ripe. It flowers in July, and the seeds ripen in the winter.

The second sort grows naturally in Canada; this is of lower growth than the former. The leaves are shorter, and sawed at their points, but the flowers of this I have not seen.

They are propagated by seeds, which should be sown soon after they are ripe upon a bed of light earth, covering them about half an inch with the same sort of earth. The seeds which are so soon put into the ground, will many of them come up the following spring; whereas those which are kept longer out of the ground, will remain a whole year in the ground before the plants will appear in the same manner as the Holly, Hawthorn, and some others; therefore the ground should not be disturbed, if the plants do not come up the first year. When the young plants come up, they may be treated in the same manner as hath been directed for the American Hawthorns, for these are full as hardy, but they delight in a moist soil and a shady situation; for in hot land they make but little progress, and rarely produce any fruit.

PRIVET. See LIGUSTRUM.

PROTEA. Lin. Gen. Plant. 104. Conocarpodendron. Boerh. Ind. alt. 2. 195. Silver-tree.

The CHARACTERS are,

The flowers are collected in an oval head; they have one common imbricated scaly perianthium. The flower is of one petal, having a tube the length of the empalement; the brim is cut into four parts, which spread open, and are equal. It has four bristly stamina the length of the petal, terminated by incumbent summits, and a roundish germen

germen with an erect bristly style, crowned by an obtuse stigma. The germen afterward turns a roundish naked seed, sitting in a distinct cell of the cone.

This genus of plants is ranged in the first section of Linnæus's fourth class, which includes those plants whose flowers have four stamina and one style.

The SPECIES are,

1. PROTEA (*Conifera*) foliis lineari-lanceolatis integerrimis acutis glabris obliquis. Lin. Sp. 138. *Protea with linear spear-shaped leaves, which are entire, sharp-pointed, smooth and oblique.*
2. PROTEA (*Argentea*) foliis lanceolatis obliquis acutis sparsis villosis-sericeis planis, floralibus verticillatis. Lin. Sp. 137. *Protea with spear-shaped oblique-pointed leaves, which are plain, silvery haired, and the flowers growing in whorls round the stalks.* Conocarpodendron foliis argenteis sericeis latissimis. Boerh. Ind. 2. p. 195. *Silver-tree.*
3. PROTEA (*Nitida*) foliis oblongo-ovatis hirsutis nitidis integerrimis. *Protea with oblong, oval, hairy, shining leaves, which are entire.* Lepidocarpodendron folio saligno lato, caule purpurascente. Boerh. Ind. alt. 2. 138. *Lepidocarpodendron, with a broad Willow leaf and a purplish stalk, otherwise called Wageboom.*

These plants are natives of the country near the Cape of Good Hope in Africa, where there is a great number of species. In the catalogue of the Leyden Garden, there are upwards of twenty sorts enumerated; not that they have them growing there, but they have good drawings of them, which were made in the country where they are natives. The three sorts here mentioned are what I had lately growing in the Chelsea Garden, but the third is now lost there.

These plants are many of them well figured in the index of the plants of the Leyden Garden, which was published by Dr. Boerhaave in 1719, by the titles of Lepidocarpodendron, Conocarpodendron, and Hypophyllocarpodendron; and, by some former writers on botany, this genus was intitled Scolymoccephalus, from the resemblance which the cones of these trees have to the head of an Artichoke.

As these plants are natives of the Cape of Good Hope, they are too tender to live abroad through the winter in England, but the first sort is hardy enough to live in a good green-house. This sort will grow to the height of ten or twelve feet, and may be trained up with a regular strait stem, and the branches will naturally form a regular large head. The leaves are long and narrow, of a shining silver colour; and as they remain the whole year, the plants make a fine appearance, when they are intermixed with others in the green-house. In the summer these may be placed in the open air in a sheltered situation; for, if they are exposed to winds, the plants will be torn, and rendered unsightly, nor will they make any progress in their growth. In warm weather they must be frequently but sparingly watered, and in cold weather this must not be too often repeated, lest it should rot their fibres.

The second sort hath a strong upright stalk covered with a purplish bark, dividing into several branches, which grow erect, garnished with broad, shining, silvery, spear-shaped leaves placed on every side, so the plants make a fine appearance, when intermixed with other exotics. This should be placed in an airy dry glass-case, where it may be protected from cold, and have as much light as possible, and in winter should have little water; this rises easily from seeds, which must be procured from the Cape of Good Hope, where it grows naturally. The seeds will sometimes remain in the ground six or eight months, and at other times the plants will appear in six weeks; therefore the best way is to sow the seeds in small pots filled with soft sandy loam, and plunge them into a moderate hot-bed; and, if the plants should not come up so soon as expected, the pots should remain in shelter till the following spring, when, if the seeds remain sound, the plants will come up. The pots in which the seeds are sown, should have but little wet, for moisture frequently causes them to

rot. When the plants appear, they should not be too tenderly treated, for they must not be kept too warm, nor should they have much wet; but in warm weather they must be exposed to the open air in a sheltered situation, and in winter protected from frost. The third sort I raised from seeds, which came from the Cape of Good Hope; these seeds were long and slender, very different in shape from those of the second sort, but the plants have some resemblance to those. The leaves are very silky and white; the stalks are purple, and grow erect, but have not as yet put out any branches.

The first sort may be propagated by cuttings, which should be cut off in April, just before the plants begin to shoot; these should be planted in small pots filled with light earth, and plunged into a moderate hot-bed, shading them from the sun, and now and then gently refreshing them with water, but it must be sparingly given, for much wet will rot them. These cuttings will put out roots by Midsummer, when they may be gently shaken out of the pots and parted, planting each in a separate small pot filled with light earth, and placed in a frame, where they may be shaded till they have taken new root; then they should be gradually inured to the open air, into which they should be removed, and treated in the same way as the old plants.

PRUNING OF TREES.

There is not any part of gardening which is of more general use than that of Pruning, and yet it is very rare to see fruit-trees skilfully managed. Almost every gardener will pretend to be a master of this business, though there are but few who rightly understand it; nor is it to be learned by rote, but requires a strict observation of the different manners of growth of the several sorts of fruit-trees, some requiring to be managed one way, and others must be treated in a quite different method, which is only to be known from carefully observing how each kind is naturally disposed to produce its fruit; for some sorts produce their fruit on the same year's wood, as Vines; others produce their fruit, for the most part, upon the former year's wood, as Peaches, Nectarines, &c. and others upon cusions or spurs, which are produced upon wood of three, four, or five, to fifteen or twenty years old, as Pears, Plums, Cherries, &c. therefore, in order to the right management of fruit-trees, there should always be provision made to have a sufficient quantity of bearing wood in every part of the trees, and at the same time there should not be a superfluity of useless branches, which would exhaust the strength of the trees, and cause them to decay in a few years.

The reasons which have been laid down for Pruning of fruit-trees are as follows: First, To preserve trees longer in a vigorous bearing state; the second is, To render the trees more beautiful to the eye; and thirdly, To cause the fruit to be larger and better tasted.

1. It preserves a tree longer in a healthy bearing state; for by pruning off all superfluous branches, so that there are no more left upon the tree than are necessary, or that can be properly nourished, the root is not exhausted in supplying useless branches, which must afterwards be cut out, whereby much of the sap will be uselessly expended.

2. By skilful Pruning of a tree it is rendered much more pleasing to the eye; but here I would not be understood to be an advocate for a sort of Pruning, which I have seen too much practised of late, viz. the drawing a regular line against the wall, according to the shape or figure they would reduce the tree to, and cutting all the branches, strong or weak, exactly to the chalked line; the absurdity of which practice will soon appear to every one, who will be at the pains of observing the difference of those branches shooting the succeeding spring. All therefore that I mean by rendering a tree beautiful is, that the branches are all pruned according to their several strengths, and are nailed at equal distances, in proportion to the different sizes of their leaves and fruit, and that no

part

part of the wall (so far as the trees are advanced) be left unfurnished with bearing wood. A tree well managed, though it does not represent any regular figure, yet will appear very beautiful to the sight, when it thus dressed and nailed to the wall.

3. It is of great advantage to the fruit; for the cutting away all useless branches, and shortening all the bearing shoots according to the strength of the tree, will render the tree more capable to nourish those fruit and branches which are left remaining, so that the fruit will be much larger and better tasted. And this is the advantage which those trees against walls or espaliers have to such as are standards, and are permitted to grow as they are naturally inclined; for it is not their being trained either to a wall or espalier which renders their fruit so much better than standards, but because the roots have a less quantity of branches and fruit to nourish, and consequently their fruit will be larger and better tasted.

The reasons for Pruning being thus exhibited, the next thing is the method of performing it; but this being fully handled under the several articles of the different kinds of fruit, I shall not repeat it again in this place, and therefore shall only add some few general instructions, which are necessary to be understood, in order to the right management of fruit-trees.

There are many persons who suppose, that if their fruit-trees are but kept up to the wall or espalier during the summer season, so as not to hang in very great disorder, and in winter to get a gardener to prune them, it is sufficient, but this is a mistake; for the greatest care ought to be employed about them in the spring, when the trees are in vigorous growth, which is the only proper season to procure a quantity of good wood in the different parts of the tree, and to displace all useless branches as soon as they are produced, whereby the vigour of the tree will be entirely distributed to such branches only as are designed to remain, which will render them strong, and more capable to produce good fruit; whereas, if all the branches are permitted to remain which are produced, some of the more vigorous will attract the greatest share of the sap from the tree, whereby they will be too luxuriant for producing fruit, and the greatest part of the other shoots will be starved, and rendered so weak, as not to be able to produce any thing else but blossoms and leaves (as hath been before mentioned;) so that it is impossible for a person, let him be ever so well skilled in fruit-trees, to reduce them into any tolerable order by Winter-pruning only, if they are wholly neglected in the spring.

There are others who do not entirely neglect their trees during the summer season, as those before-mentioned, but yet do little more good to them by what they call Summer-pruning; for these persons neglect their trees at the proper season, which is in April and May, when their shoots are produced, and only about Midsummer go over them, nailing in all their branches, except such as are produced fore-right from the wall, which they cut out, and at the same time often shorten most of the other branches; all which is entirely wrong practice, for those branches, which are intended for bearing the succeeding year, should not be shortened during the time of their growth, which will cause them to produce one or two lateral shoots from the eyes below the place where they were stopped, which shoots will draw much of the strength from the buds of the first shoot, whereby they are often flat, and do not produce their blossoms; and, if those two lateral shoots are not entirely cut away at the Winter-pruning, they will prove injurious to the tree, as the shoots which these produce, will be what the French call water shoots; and in suffering those luxuriant shoots to remain upon the tree until Midsummer before they are displaced, they will exhaust a great share of the nourishment from the other branches (as was before observed;) and, by shading the fruit all the spring season, when they are cut away, and the other branches fastened to the wall, the fruit, by be-

ing so suddenly exposed, will receive a very great check, which will cause their skins to grow tough, and thereby render them less delicate. This is to be chiefly understood of stone fruit and Grapes, but Pears and Apples being much hardier, suffer not so much; though it is a great disadvantage to those also to be thus managed.

It must also be remarked, that Peaches, Nectarines, Apricots, Cherries, and Plums, are always in the greatest vigour, when they are the least maimed by the knife; for where these trees have large amputations, they are very subject to gum and decay; so that it is certainly the most prudent method carefully to rub off all useless buds when they are first produced, and pinch others, where new shoots are wanted to supply the vacancies of the wall, by which management trees may be so ordered, as to want but little of the knife in Winter-pruning, which is the surest way to preserve these trees healthful, and is performed with less trouble than the common method.

The management of Pears and Apples is much the same with these trees in summer, but in winter they must be very differently pruned; for as Peaches and Nectarines for the most part produce their fruit upon the former year's wood, therefore they must have their branches shortened according to their strength, in order to produce new shoots for the succeeding year; so Pears, Apples, Plums, and Cherries, on the contrary, producing their fruit upon cusions or spurs, which come out of the wood of five, six, or seven years old, should not be shortened, because thereby those buds, which were naturally disposed to form these cusions or spurs, would produce wood branches, whereby the trees would be filled with wood, but never produce much fruit; and as it often happens that the blossom buds are first produced at the extremity of the last year's shoot, by shortening the branches the blossoms are cut away, which should always be carefully avoided.

There are several authors who have written on the subject of Pruning in such a prolix manner, that it is impossible for a learner to understand their meaning. These have described the several sorts of branches which are produced on fruit-trees; as wood branches, fruit branches, irregular branches, false branches, and luxuriant branches, all which they assert every person, who pretends to Pruning, should distinguish well; whereas there is nothing more in all this but a parcel of words to amuse the reader, without any real meaning; for all these are comprehended under the description already given of luxuriant or useless branches, and such as are termed useful or fruit-bearing branches; and, where due care is taken in the spring of the year to displace these useless branches (as was before directed,) there will be no such thing as irregular, false, or luxuriant branches at the Winter-pruning; therefore it is to no purpose to amuse people with a cant of words, which, when fully understood, signify just nothing at all.

But since I have explained the different methods of Pruning the several sorts of fruits under the respective articles, I shall forbear repeating it again in this place, but shall only give some general hints for the Pruning of standard fruit-trees, and so conclude.

First, you should never shorten the branches of these trees, unless it be where they are very luxuriant, and grow irregular on one side of the tree, attracting the greatest part of the sap of the tree, whereby the other parts are unfurnished with branches, or rendered very weak; in which case the branch should be shortened down as low as is necessary, in order to obtain more branches, to fill up the hollow of the trees; but this is only to be understood of Pears and Apples, which will produce shoots from wood of three, four, or more years old, whereas most sorts of stone fruit will gum and decay after such amputations.

But from hence I would not have it understood, that I would direct the reducing of these trees into an exact spherical figure, since there is nothing more de-
testable than to see a tree (which should be permitted

to grow as it is naturally disposed, with its branches produced at proportionable distances, according to the size of the fruit,) by endeavouring to make it exactly regular at its head, so crowded with small weak branches as to prevent the air from passing between them, which will render the trees incapable to produce fruit. All that I intend by this stopping of luxuriant branches, is only when one or two such happen on a young tree, where they entirely draw all the sap from the weaker branches, whereby they starve them, then it is proper to use this method, which should be done in time, before they have exhausted the roots too much.

Whenever this happens to stone fruit, which suffer much more by cutting than the former sorts, it should be remedied by stopping or pinching those shoots in the spring, before they have obtained too much vigour, which will cause them to push out side-branches, whereby the sap will be diverted from ascending too fast to the leading branch (as hath been directed for wall-trees,) but this must be done with caution.

You must also cut out all dead or decayed branches, which cause their heads to look very ragged, especially at the time when the leaves are upon the tree; these being destitute of them, have but a despicable appearance; besides, these will attract noxious particles from the air, which are injurious to the trees, therefore the sooner they are cut out the better. In doing of this you should observe to cut them close down to the place where they were produced, otherwise that part of the branch left will decay, and prove equally hurtful to the tree; for it seldom happens, when a branch begins to decay, that it does not die quite down to the place where it was produced; and, if any part is permitted to remain long uncut, does often infect some of the other parts of the tree. If the branches are large which you cut off, it will be very proper, after having smoothed the cut part exactly even with a knife, chisel, or hatchet, to put on a plaster of grafting clay, which will prevent the wet from soaking into the tree at the wounded part.

All such branches as run cross each other should also be cut out, for these not only occasion a confusion in the head of the tree, but, by lying over each other, rub off their bark by their motion, and very often occasion them to canker, to the great injury of the tree; and on old trees (especially Apples) there are often young vigorous shoots from the old branches near the trunk, which grow upright into the head of the trees. These therefore should carefully be cut out every year, lest, by being permitted to grow, they fill the tree too full of wood, which should always be guarded against, since it is impossible for such trees to produce so much, or so good fruit as those, whose branches grow at a farther distance, whereby the sun and air freely pass between them in every part of the tree.

These are the general directions which are proper to be given in this place, since not only the particular methods, but also the proper seasons for Pruning all the different kinds of fruit, are fully exhibited under their several articles.

PRUNELLA. Lin. Gen. Plant. 735. Tourn. Inst. R. H. 84. Self-heal.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, with two lips; the upper is plain, broad, and slightly indented in three parts; the under is erect, acute-pointed, and cut into two segments; the flower is of the ringent kind, having a short cylindrical tube with oblong chaps; the upper lip is concave, nodding, and entire; the under is reflexed, trifid, and obtuse. It hath four oval-shaped stamina, two of which are longer than the other, with simple summits inserted to the stamina, and four germen with a slender style, inclining to the upper lip of the flower, crowned by an indented stigma. The germen afterward become four seeds, sitting in the empalement of the flower.

This genus of plants is ranged in the first section of Linnaeus's fourteenth class, intitled Didynamia Gym-

nospermia, from the flowers having two long and two short stamina, which are succeeded by four naked seeds sitting in the empalement.

The SPECIES are,

1. PRUNELLA (*Vulgaris*) foliis omnibus ovato-oblongis petiolatis. Lin. Sp. Plant. 837. *Self-heal with all the leaves oblong, oval, having foot-stalks. Brunella major, folio non dissecto. C. B. P. 260. Greater Self-heal with entire leaves.*
2. PRUNELLA (*Laciniata*) foliis ovato-oblongis petiolatis, supremis quatuor lanceolatis dentatis. Lin. Sp. Plant. 837. *Self-heal with oblong oval leaves having foot-stalks, whose upper part of the leaves are cut into four segments. Brunella folio laciniato. C. P. B. 261. Self-heal with cut leaves.*
3. PRUNELLA (*Hyssopifolia*) foliis lanceolato-linearibus ciliatis sessilibus. Sauv. Monsp. 141. *Self-heal with linear spear-shaped leaves sitting close to the stalks. Brunella Hyssopifolia. C. B. P. 261. Self-heal with an Hyssop leaf.*
4. PRUNELLA (*Canadensis*) foliis linearibus sessilibus glabris, internodiis longissimis, spicis interruptis. *Self-heal with linear smooth leaves sitting close to the stalks, the spaces between the joints very long, and the spikes of flowers broken.*
5. PRUNELLA (*Sulphurea*) foliis oblongis pinnato-incisis villosis, infimis petiolatis, summis sessilibus. *Self-heal with oblong hairy leaves cut in form of winged leaves, the lower having foot-stalks, but the upper sit close to the stalks. Brunella folio laciniato, flore sulphureo elegantissimo. Boerh. Ind. alt.*
6. PRUNELLA (*Caroliniana*) foliis lanceolatis integerrimis, infimis petiolatis, summis sessilibus, internodiis prælongis. *Self-heal with entire spear-shaped leaves, the lower having long foot-stalks, but the upper sit close to the stalk, and the joints of the stalk are distant. Brunella Caroliniana magno flore dilute caeruleo, internodiis prælongis. Act. Phil. N° 395.*
7. PRUNELLA (*Nova Anglia*) foliis oblongis mucronatis petiolatis, spicis florum crassissimis. *Self-heal with oblong pointed leaves having foot-stalks, and very thick spikes of flowers. Brunella Novæ Angliæ major, foliis longius mucronatis. Hort. Chelf.*

There are some other varieties, if not distinct species, of this genus, than are here enumerated; but it is difficult to determine the species, some of them approaching so near to others, as scarcely to be distinguished from them; the first sort grows naturally in England, and is used in medicine; the dried herb is frequently imported from Switzerland, among those which are called vulnerary herbs, of which this is supposed to be one of the best.

The second sort is less common than the first, and of this there are two or three varieties, which some writers on botany have enumerated as distinct species; one of these has narrower leaves, which are cut into finer segments; this is titled *Verbennæ folio*; but as the plants raised from the same seeds are very subject to vary, so it is difficult to determine if it is really a different plant.

The third sort grows naturally in Italy and the south of France; the leaves of this sort are narrower than those of either of the former, and are covered on both sides with fine hairs, and have very short foot-stalks; the spikes of flowers are slender, and are of a pale blue colour; this flowers in July, and the seeds ripen in the autumn.

The fourth sort grows naturally in North America; the leaves of this are pretty long and narrow, shaped like those of the third sort, but are smooth, sitting close to the stalk; the spikes of flowers are longer, and the whorls of flowers are separated.

It is uncertain where the fifth sort grows naturally, though I think Dr. Boerhaave, late professor of botany at Leyden, told me, he received the seeds from Austria; the stalks of this sort generally spread open, and prostrate near the ground; these are hairy, and garnished with oblong leaves, which are also hairy, and cut on their edges somewhat like winged leaves; the stalks are terminated by close spikes of flowers, of a sulphur

a sulphur colour; this flowers and ripens its seeds about the same time with the former.

The sixth sort grows naturally in Carolina, from whence I received the seeds; the stalks of this sort rise more than eight inches high, and are garnished with oblong leaves; those toward the bottom have long foot-stalks, but those on the top sit close to the stalks; the spikes of flowers are large and entire; they are of a pale blue colour, appearing at the same time with those of the two former sorts, and the seeds ripen in September.

The seeds of the seventh sort were first sent me from New England; but since then, I have received more from Virginia, so I suppose the plant grows naturally in several parts of North America. The leaves of this are large, smooth, and end in sharp points; the stalks are brown; they rise eight or nine inches high, and are terminated by thick spikes of blue flowers, which appear in July, and are succeeded by seeds which ripen in September.

These plants are seldom cultivated in any gardens, unless by such who have an inclination for the study of botany, as they are plants which make little appearance; however, those who are desirous to cultivate any of the species, may do it by sowing the seeds in the autumn, soon after they are ripe, when they will succeed much sooner, and with greater certainty, than if they are sown in the spring; for the seeds which are sown at that season seldom grow till a twelve-month after, and sometimes do not succeed. When the plants come up, they require no other care but to thin them where they are too close, and keep them clean from weeds. They will thrive upon any soil or situation, but best on a moist soil and a shady situation, where, if the ground is not too good, they will live three or four years, but in rich land they seldom continue longer than two years; therefore to continue the species, it will be proper to sow their seeds every year, or every other year.

PRUNUS. Tourn. Inst. R. H. 622. tab. 398. Lin. Gen. Plant. 546. The Plum-tree.

The CHARACTERS are,

The flower hath a bell-shaped empalement of one leaf, cut into five parts; it hath five large roundish petals which spread open, and are inserted in the empalement; and from twenty to thirty stamina, which are near as long as the petals, and are also inserted in the empalement, terminated by twin summits. It has a roundish germen, supporting a slender style, crowned by an orbicular stigma. The germen afterward turns to a roundish fruit, inclosing a nut of the same form.

This genus of plants is ranged by Dr. Linnæus in the first section of his twelfth class, which includes those plants whose flowers have many stamina inserted to the empalement; and has joined to this genus the Padus, Cerasus, and Armeniaca, making them only species of the same genus; which, according to his system of ranging the plants, may be allowed; yet in a treatise of this kind it would rather puzzle the practitioners of the art of gardening to follow him, for which reason I have kept them separate.

I shall not abridge this article, but continue to mention the varieties of this fruit which are cultivated in the English gardens.

The SPECIES are,

1. **PRUNUS** (*Jaunbative*) fructu parvo præcoci. *The white Primordian.* This is a small, longish, white Plum, of a clear yellow colour, covered over with a white floss, which easily wipes off. It is a pretty good bearer, and, for its coming very early, one tree may have a place in a large garden of fruit, but it is mealily, and has little flavour. This ripens the middle or latter end of July.
2. **PRUNUS** (*Damas Noir*) fructu magno crasso subacido. Tourn. *The early Damask, commonly called the Morocco Plum.* This is a middle sized Plum, of a round shape, divided with a furrow in the middle (like Peaches.) The outside is of a dark black colour, covered with a light Violet bloom; the flesh is yellow, and parts

from the stone. It ripens the end of July, and is esteemed for its goodness.

3. **PRUNUS** (*Small Damas*) fructu parvo dulci atro-cæruleo. Tourn. *The little black Damask Plum.* This is a small black Plum covered with a light Violet bloom. The juice is richly sugared; the flesh parts from the stone, and it is a good bearer. Ripe the beginning of August.
4. **PRUNUS** (*Gross Damas*) fructu magno dulci atro-cæruleo. Tourn. *Gross Damas Violet de Tours, i. e. great Damask Violet of Tours.* This is a pretty large Plum, inclining to an oval shape. The outside is of a dark blue covered with a Violet bloom; the juice is richly sugared; the flesh is yellow, and parts from the stone. Ripe in August.
5. **PRUNUS** (*Orleans*) fructu rotundo atro rubente. *The Orleans Plum.* The fruit is so well known to almost every person, that it is needless to describe it; it is a very plentiful bearer, which has occasioned its being so generally planted by those persons who supply the markets with fruit, but it is an indifferent Plum. It ripens in August.
6. **PRUNUS** (*Fotheringham*) fructu oblongo atro-rubente. *The Fotheringham Plum.* This fruit is somewhat long, deeply furrowed in the middle. The flesh is firm, and parts from the stone; the juice is very rich. This ripens in August.
7. **PRUNUS** (*Perdigron*) fructu nigro, carne durâ. Tourn. *The Perdigron Plum.* This is a middle-sized Plum of an oval shape. The outside is of a very dark colour, covered over with a Violet bloom; the flesh is firm, and full of an excellent rich juice. This is greatly esteemed by the curious. Ripe in August.
8. **PRUNUS** (*Violet Perdigron*) fructu magno è violaceo rubente suavissimo saccharato. Tourn. *The Violet Perdigron Plum.* This is a large fruit, rather round than long, of a bluish red colour on the outside. The flesh is of a yellowish colour, pretty firm, and closely adheres to the stone; the juice is of an exquisite rich flavour. This ripens in August.
9. **PRUNUS** (*White Perdigron*) fructu ovato ex albo flavescente. *The white Perdigron Plum.* This is a middling Plum, of an oblong figure. The outside is yellow, covered with a white bloom; the flesh is firm, and well tasted. It is a very good fruit to eat raw, or for sweetmeats, having an agreeable sweetness mixed with an acidity. It ripens the end of August.
10. **PRUNUS** (*Imperial*) fructu ovato magno rubente. Tourn. *The red imperial Plum, sometimes called the red Bonum Magnum.* This is a large oval-shaped fruit, of a deep red colour, covered with a fine bloom. The flesh is very dry, and very indifferent to be eaten raw, but is excellent for making sweetmeats; this is a great bearer. Ripe in September.
11. **PRUNUS** (*Bonum Magnum*) fructu ovato magno flavescente. Tourn. *White imperial Bonum Magnum, white Holland, or Mogul Plum.* This is a large oval-shaped fruit, of a yellowish colour, powdered over with a white bloom. The flesh is firm, and adheres closely to the stone; the juice is of an acid taste, which renders it unpleasant to be eaten raw, but it is very good for baking or sweetmeats. It is a great bearer, and is ripe the middle of September.
12. **PRUNUS** (*Cheston*) fructu ovato cæruleo. *The Cheston Plum.* This is a middle-sized fruit of an oval figure. The outside is of a dark blue, powdered over with a Violet bloom; the juice is rich, and it is a great bearer. Ripe the middle of September.
13. **PRUNUS** (*Apricot*) fructu maximo rotundo flavo & dulci. Tourn. *Prune d'Abriot, i. e. the Apricot Plum.* This is a large round fruit of a yellow colour on the outside, powdered over with a white bloom. The flesh is firm and dry, of a sweet taste, and comes clean from the stone. This ripens the end of September.
14. **PRUNUS** (*Maitre Claud*) fructu subrotundo, ex rubro & flavo mixto. *The Maitre Claud.* Although this name is applied to this fruit, yet it is not what the French

French so call. This a middle-sized fruit, rather round than long, of a fine mixed colour between red and yellow. The flesh is firm, parts from the stone, and has a delicate flavour. Ripe the end of September.

15. PRUNUS (*Diaprie*) fructu rubente dulcissimo. Tourn. *La Rochecourbon, or Diaprie rouge, i. e. the red Diaper Plum.* This is a large round fruit, of a reddish colour, powdered over with a Violet bloom; the flesh adheres closely to the stone, and is of a very high flavour. Ripe the end of August.
16. PRUNUS fructu rotundo flavescente. *La petite Reine Claude, i. e. the little Queen Claudia.* This is a small round fruit, of a whitish yellowish colour, powdered over with a pearl-coloured bloom; the flesh is firm and thick, quits the stone, and its juice is richly sugared. Ripe the end of August.
17. PRUNUS fructu rotundo nigro-purpureo majori dulci. Tourn. *Myrobalan Plum.* This is a middle-sized fruit, of a round shape; the outside is a dark purple, powdered over with a Violet bloom; the juice is very sweet. It is ripe the end of August.
18. PRUNUS fructu rotundo è viridi flavescente, carne duro suavissimo. *La grosse Reine Claude, i. e. the large Queen Claudia, by some the Dauphiny.* At Tours it is called the Abricot verd, i. e. green Apricot; at Rouen, Le verte bonne, i. e. the good green; and in other places, Damas verd, i. e. green Damask, or Tromp-vallet, the Servants Cheat. This is one of the best Plums in England; it is of a middle size, round, and of a yellowish green colour on the outside; the flesh is firm, of a deep green colour, and parts from the stone; the juice has an exceeding rich flavour, and it is a great bearer. Ripe the middle of September. This Plum is confounded by most people in England, by the name of Green Gage; but this is the sort which should be chosen, although there are three or four different sorts of Plums generally sold for it, one of which is small, round, and dry; this quits the stone, and is later ripe, so not worth preserving.
19. PRUNUS fructu amygdalino. Tourn. *Rognon de Coq, i. e. Cock's Testicles.* This is an oblong fruit, deeply furrowed in the middle, so as to resemble the testicles; it is of a whitish colour on the outside, streaked with red; the flesh of it adheres firmly to the stone, and it is late ripe.
20. PRUNUS fructu rotundo flavo dulcissimo. *Drap d'Or, i. e. the Cloib of Gold Plum.* This is a middle sized fruit, of a bright yellow colour, spotted or streaked with red on the outside; the flesh is yellow, and full of an excellent juice. It is a plentiful bearer, and ripens about the middle of September.
21. PRUNUS fructu cerei coloris. Tourn. *Prune de Sainte Catharine, i. e. St. Catharine Plum.* This is a large oval-shaped fruit, somewhat flat; the outside is of an amber colour, powdered over with a whitish bloom, but the flesh is of a bright yellow colour, is dry and firm, adheres closely to the stone, and has a very agreeable sweet taste. This ripens at the end of September, and is very subject to dry upon the tree, when the autumn proves warm and dry. This makes fine sweetmeats, and is a plentiful bearer.
22. PRUNUS fructu ovato rubente dulci. *The Royal Plum.* This is a large fruit of an oval shape, drawing to a point next the stalk; the outside is of a light red colour, powdered over with a whitish bloom; the flesh adheres to the stone, and has a fine sugary juice. This ripens the middle of September.
23. PRUNUS fructu parvo ex viridi flavescente. Tourn. *La Mirabelle.* This is a small round fruit, of a greenish yellow on the outside; the flesh parts from the stone, is of a bright yellow colour, and has a fine sugary juice. This is a great bearer, ripens the end of August, and is excellent for sweetmeats.
24. PRUNUS Brigonienfis, fructu suavissimo. Tourn. *Prune de Brignole, i. e. the Brignole Plum.* This is a large oval-shaped fruit, of a yellowish colour, mixed with red on the outside; the flesh is of a bright yellow colour, is dry, and of an excellent rich flavour.

This ripens the middle of September, and is esteemed the best Plum for sweetmeats yet known.

25. PRUNUS fructu magno è violaceo rubente serotino. Tourn. *Imperatrice, i. e. the Empress.* This is a large round fruit, of a Violet red colour, very much powdered with a whitish bloom; the flesh is yellow, cleaves to the stone, and is of an agreeable flavour. This ripens about the beginning of October.
 26. PRUNUS fructu ovato maximo flavo. Tourn. *Prune de Monsieur, i. e. Monsieur's Plum.* This is sometimes called the Wentworth Plum. It is a large oval-shaped fruit, of a yellow colour both within and without, very much resembling the Bonum Magnum, but the flesh of this parts from the stone, which the other doth not. This ripens towards the latter end of September, and is very good to preserve; but the juice is too sharp to be eaten raw. It is a great bearer.
 27. PRUNUS fructu majori rotundo rubro. Tourn. *Prune Cerizette, i. e. the Cherry Plum.* This fruit is commonly about the size of the Ox-heart Cherry, is round, and of a red colour; the stalk is long like that of a Cherry, which this fruit so much resembles, as not to be distinguished therefrom at some distance. The blossoms of this tree come out very early in the spring, and being tender, are very often destroyed by cold, but it affords a very agreeable prospect in the spring; for these trees are generally covered with flowers, which open about the same time as the Almonds; so that when they are intermixed therewith, they make a beautiful appearance before many other sorts put out; but by this blossoming so early, there are few years that they have much fruit.
 28. PRUNUS fructu albo oblongiusculo acido. Tourn. *The white Pear Plum.* This is a good fruit for preserving, but is very unpleasant if eaten raw; it is very late ripe, and seldom planted in gardens, unless for stocks to bud some tender sorts of Peaches upon, for which purpose it is esteemed the best amongst all the sorts of Plums.
 29. PRUNUS Mytellinum. Park. *The Muscle Plum.* This is an oblong flat Plum, of a dark red colour; the stone is large, and the flesh but very thin and not well tasted, so that its chief use is for stocks, as the former.
 30. PRUNUS fructu parvo violaceo. *The St. Julian Plum.* This is a small fruit, of a dark Violet colour, powdered over with a mealy bloom; the flesh adheres closely to the stone, and in a fine autumn will dry upon the tree. The chief use of this Plum is for stocks, to bud the more generous kinds of Plums and Peaches upon; as also for the Bruxelles Apricot, which will not thrive so well upon any other stock.
 31. PRUNUS sylvestris major. J. B. *The black Bullace-tree.* This grows wild in the hedges in divers parts of England, and is rarely cultivated in gardens.
 32. PRUNUS sylvestris, fructu majore albo. Raii Syn. *The white Bullace-tree.* This grows wild as the former, and is seldom cultivated in gardens.
 33. PRUNUS sylvestris. Ger. Emac. *The Black-thorn, or Slee-tree.* This is very common in the hedges almost every where; the chief use of this tree is to plant for hedges, as White-thorn, &c. and being of quick growth, is very proper for that purpose.
- All the sorts of Plums are propagated by budding or grafting them upon stocks of the Muscle, White Pear, St. Julian, Bonum Magnum, or any other sorts of free-shooting Plums. The manner of raising these stocks hath been already exhibited under the article of NURSERIES, therefore need not be repeated again in this place; but I would observe, that budding is much preferable to grafting for these sorts of stone fruit-trees, which are very apt to gum, wherever there are large wounds made on them.
- The trees should not be more than one year's growth from the bud when they are transplanted, for if they are older, they seldom succeed so well, being very subject to canker; or if they take well to the ground, commonly produce only two or three luxuriant branches, therefore it is much more advisable to chuse young plants.

The manner of preparing the ground (if for walls) is the same as for Peaches; as is also pruning the roots and planting, therefore I shall forbear repeating it again. The distance which these trees should be planted at, must not be less than twenty-four feet against high walls; and if the wall is low, they should be placed thirty feet asunder.

Plums should have a middling soil, neither too wet and heavy, nor over light and dry, in either of which extremes they seldom do so well; and those sorts which are planted against walls, should have an east or south-east aspect, which is more kindly to these fruits than a full south aspect, on which they are subject to shrivel, and be very dry; and many sorts will be extreme mealy, if exposed too much to the heat of the sun; but most sorts will ripen extremely well on espaliers, if rightly managed.

There are some persons who plant Plums for standards, in which method some of the ordinary sorts will bear very well; but then the fruit will not be near so fair as those produced on espaliers, and will be more in danger of being bruised or blown down by strong winds. The distance of placing them for espaliers must be the same as against walls, as must also their pruning and management; so that whatever may be hereafter mentioned for one, should be likewise understood for both.

Plums do not only produce their fruit upon the last year's wood, but also upon cufions or spurs, which come out of wood that is many years old; so that there is not a necessity of shortening the branches, in order to obtain new shoots annually, in every part of the tree (as in Peaches, Nectarines, &c. hath been directed) since the more these trees are pruned, the more luxuriant they grow, until the strength of them is exhausted, and then they gum and spoil; therefore the safest method to manage these trees is, to lay in their shoots horizontally, as they are produced, at equal distances, in proportion to the length of their leaves; and where there is not a sufficient quantity of branches to fill up the vacancies of the tree, there the shoots may be pinched the beginning of May (in the manner as hath been directed for Peaches, &c.) which will cause them to produce some lateral branches to supply those places; and during the growing season, all fore-right shoots should be displaced, and such as are to remain must be regularly trained in to the wall or espalier, which will not only render them beautiful, but also give to each part of the trees an equal advantage of sun and air; and hereby the fruit will be always kept in a ductile growing state, which they seldom are, when overshadowed with shoots some part of the season, and then suddenly exposed to the air, by taking off, or training those branches in their proper position.

With thus carefully going over these trees in the growing season, there will be but little work to do to them in winter; for when the branches are shortened, the fruit is cut away, and the number of shoots increased; for whenever a branch is shortened, there are commonly two or more shoots produced from the eyes immediately below the cut; so that by thus unskilfully pruning, many persons crowd their trees with branches, and thereby render what little fruit the trees produce, very small and ill-tasted; which is very commonly found in too many gardens, where the manager, perhaps, thinks himself a complete master of his business; for nothing is more common than to see every branch of a fruit-tree pass the discipline of the knife, however disagreeable it be to several sorts of fruits. And it is common to see these trees planted at the distance of fourteen or sixteen feet, so that the walls are in a few years covered with branches; and then all the shoots are cut and mangled with the knife, so as to appear like a stumped hedge, and produce little fruit; therefore the only way to have Plum-trees in good order, is to give them room, and extend their branches at full length.

Those few rules before laid down, will be sufficient, if due observation be joined therewith, to instruct any

person in the right management of these sorts of fruit-trees; therefore I shall not say any more on that subject, lest by multiplying instructions, it may render it more obscure to a learner.

PSEUDOACACIA. See ROBINIA.

PSEUDODICTAMNUS. See MARRUBIUM.

PSIDIUM. Lin. Gen. Plant. 541. Guajava. Tourn. Inst. R. H. 660. tab. 443. The Guava-tree.

The CHARACTERS are,

The flower has a bell-shaped empalement of one leaf, divided into five oval points at the top. It hath five oval, concave, spreading petals, indented in the empalement, with a great number of stamina which are shorter than the petals, and are inserted in the empalement, terminated by small summits. It has a roundish germen situated under the flower, supporting a long awl-shaped style, crowned by a simple stigma; the germen afterward becomes a large oval fruit crowned by the empalement, inclosing a great number of small seeds.

This genus of plants is ranged in the first section of Linnæus's twelfth class, which includes those plants whose flowers have many stamina which are inserted in the empalement, and one style.

The SPECIES are,

1. PSIDIUM (*Pyriferum*) foliis ovato-lanceolatis, pedunculis unifloris. *Psidium with oval spear-shaped leaves, and one flower on each foot-stalk.* Guajava alba dulcis. Hort. Amst. vol. i. p. 121. *The sweet white Guava.*
2. PSIDIUM (*Pomiferum*) foliis ovatis, pedunculis trifloris. *Psidium with oval leaves and foot-stalks with three flowers.* Guajabo pomifera Indica, pomis rotundis. C. B. P. 437. *The red Guava.*

Both these sorts grow naturally in the East and West-Indies; and there is also a third with a large white fruit, but I do not know whether this is a variety of the common Guava, or of that with the small white fruit; though I am inclined to believe it is the former, because I have raised many plants from the seeds of the small white Guava, which have produced fruit in the Chelsea Garden, and have not varied from their parent plant.

The common red Guava hath a pretty thick trunk, which rises twenty feet high, covered with a smooth bark, and divides into many branches toward the top; these are angular, and garnished with oval leaves two inches and a half long, and one inch and a half broad in the middle, rounded at both ends; they have a strong midrib, and many veins running toward the sides, of a light green colour, standing opposite upon very short foot-stalks. From the wings of the leaves the flowers come out upon foot-stalks, about an inch and a half long; they are composed of five large, roundish, concave, white petals, which are inserted in the empalement, and within these are a great number of stamina which are shorter than the petals, terminated by small summits; these stamina are also inserted in the empalement. Under the flower is situated a roundish germen, supporting a very long awl-shaped style, crowned by a simple stigma. After the flower is past, the germen becomes a large oval fruit, shaped like a Pomegranate, having one cell, crowned by the empalement of the flower, and filled with small seeds; the fruit, when ripe, has an agreeable odour. They are much eaten in the West-Indies, both by men and beasts; and the seeds, which pass whole through the body, and are voided with the excrement grow, whereby the trees are spread over the ground where they are permitted to grow. This fruit is very astringent, and nearly of the same quality with Pomegranate, so should be avoided by those persons who are subject to be costive.

The large white sort grows naturally in the islands of the West-Indies, and is often found intermixed with the former, so is supposed to be only an accidental variety arising from the same seeds. This differs from the former in the colour of the midrib of the leaves, which in this are pale, but those of the former are red. The flowers and fruit of this are larger, and the inside of the fruit is white.

The leaves of the small white Guava are like those of the larger, but the branches of the tree are not so angular; the flowers are much smaller, and the fruit is no larger than a middling Gooseberry, but when ripe has a very strong aromatic flavour. This flowers in June, and the fruit ripens in autumn.

These plants are propagated by seeds, which must be procured from the countries where they naturally grow; if these are brought over in the entire fruit, gathered full ripe, the seeds will more certainly succeed; these should be sown in pots filled with rich kitchen-garden earth, and plunged into a hot-bed of tanners bark, giving them water from time to time as the earth dries; in about six weeks the plants will appear (if the seeds are good) and must have free air admitted to them in proportion to the warmth of the season; when the plants have obtained strength enough to be removed, they should be each planted in a small pot, filled with the like rich earth, and plunged into a fresh hot-bed, shading them from the sun until they have taken new root; then they should have a large share of free air admitted to them every day in warm weather, to prevent their drawing up weak; they must also be frequently refreshed with water in summer. When the plants have filled these small pots with their roots, they should be shaken out and their roots pared, then put into larger pots filled with the same sort of earth, and plunged into the hot-bed again, where they should remain till autumn, when they must be plunged into the tan-bed in the stove: during the winter they should have a moderate warmth, and not too much water, and in summer they will require plenty of wet, and in hot weather a great share of air; with this management the plants will produce flowers and fruit the third year, and may be continued a long time.

PSORALEA. Lin. Gen. Plant. 801. Flor. Leyd. Prod. 372. Barba Jovis. Boerh. Ind. alt. 2. 40.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five parts, the lower segments being twice the length of the other. The flower is of the butterfly kind, it hath five petals; the standard is roundish, and indented at the top. The wings are small, obtuse, and moon-shaped; the keel is moon-shaped, and composed of two petals. It hath nine stamina joined together, and one bristly staminal standing separate, terminated by roundish summits, with a linear germen supporting an awl-shaped rising style, crowned by an obtuse stigma. The germen afterward turns to a slender compressed pod, inclosing one kidney-shaped seed.

This genus of plants is ranged in the third section of Linnæus's seventeenth class, which includes those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. **PSORALEA (Pinnata)** foliis pinnatis, floribus axillari-bus. Hort. Upsal. 225. *Psoralea with winged leaves, and flowers proceeding from the sides of the stalks.* Barba Jovis Africana, foliis viridibus pinnatis, flore cæruleo. Boerh. Ind. alt. 2. p. 40. *African Jupiter's Beard, with green winged leaves and a blue flower.*
2. **PSORALEA (Hirta)** foliis ternatis foliolis ovatis, caule fruticoso hirsuto, floribus spicatis terminalibus. *Psoralea with trifoliate oval leaves, a hairy shrubby stalk, and flowers growing in spikes terminating the branches.* Barba Jovis Americana frutescens, foliis subrotundis, floribus spicatis purpureis. Houst. MSS. *Shrubby American Jupiter's Beard, with roundish leaves and purple spiked flowers.*
3. **PSORALEA (Procumbens)** foliis pinnatis argenteis, caulibus procumbentibus, floribus axillaribus. *Psoralea with silvery winged leaves, trailing stalks, and flowers proceeding from the sides of the stalks.* Barba Jovis Malabarica annua procumbens argentea, floribus minimis purpureis. Ed. Prior. *Annual, trailing, silvery Jupiter's Beard of Malabar, with the least purple flowers.*
4. **PSORALEA (Scandens)** foliis pinnatis, caule ramoso scandente, floribus alaribus sessilibus. *Psoralea with winged leaves, a climbing branching stalk, and flowers sitting close at the wings of the stalk.* Barba Jovis Ame-

ricana scandens, floribus cæruleis, ad alas foliorum conglomeratis. Houst. MSS. *Climbing American Jupiter's Beard, with blue flowers growing in clusters at the wings of the leaves.*

5. **PSORALEA (Capitata)** foliis ternatis, caule fruticoso ramulissimo, floribus capitatis pedunculatis alaribus. *Psoralea with trifoliate leaves, a very branching shrubby stalk, and flowers growing in heads, which have foot-stalks proceeding from the wings of the leaves.* Barba Jovis Americana frutescens hirsuta, floribus cæruleis conglomeratis. Houst. MSS. *Shrubby, hairy, American Jupiter's Beard, with blue clustered flowers.*
6. **PSORALEA (Annua)** foliis pinnatis, spicis terminalibus. Lin. Sp. Plant. 764. *Psoralea with winged leaves, and flowers growing in spikes terminating the branches.* Barba Jovis Americana annua, humilis, ramulissima, floribus cæruleis spicatis. Houst. MSS. *Low, very branching, annual, American Jupiter's Beard, with blue spiked flowers.*
7. **PSORALEA (Humilis)** foliis pinnatis, foliolis rotundioribus villosis, floribus capitatis alaribus terminalibusque, caule fruticoso. *Psoralea with winged leaves having hairy round lobes, flowers growing in heads from the wings of the leaves, and at the end of the branches, and a shrubby stalk.* Barba Jovis Americana, humilis rotundifolia & villosa, flore vario. Houst. MSS. *Low American Jupiter's Beard, with a round hairy leaf and a variable flower.*
8. **PSORALEA (Bituminosa)** foliis omnibus ternatis, pedunculis capitatis. Hort. Upsal. 225. *Psoralea with trifoliate leaves, and flowers growing in heads.* Trifolium bitumen redolens. C. B. P. 327. *Trefoil with a bituminous scent.*
9. **PSORALEA (Angustifolia)** foliis ternatis, foliolis ovato-lanceolatis, floribus capitatis. *Psoralea with trifoliate leaves having oval spear-shaped lobes, and flowers growing in heads.* Trifolium bitumen redolens angustifolium ac sempervirens. Boerh. Ind. alt. 2. p. 32. *Trefoil smelling like Bitumen, with a narrow evergreen leaf.*
10. **PSORALEA (Corylifolia)** foliis simplicibus ovatis. Hort. Upsal. 225. *Psoralea with oval simple leaves.* Loto affinis coryli folio. Dodart. Acad. Scien. 4. p. 289. The first sort grows naturally at the Cape of Good Hope, from whence I have frequently received the seeds. This rises with a soft shrubby stalk four or five feet high, dividing into several branches, which are garnished with deep green winged leaves, composed of three or four pair of very narrow linear lobes, terminated by an odd one, standing upon short foot-stalks, which come out without any order on every side the branches. The flowers sit very close to the branches, coming out from the wings of the leaves; they are often in clusters. The standard, which is erect and reflexed at the top, is of a fine blue; the wings are pale, and the keel white; these are succeeded by short pods the length of the empalement, each containing one kidney-shaped seed. It flowers great part of summer, and the seeds ripen in autumn. This is easily propagated by seeds, which should be sown upon a moderate hot-bed; and when the plants come up, they must not be drawn weak, for as they are not tender, so they should have air and but little heat. When they are fit to remove, they should be planted in separate small pots, filled with light earth, and plunged again into the bed, shading them from the sun till they have taken new root; then they should be gradually inured to the open air, into which they should be removed about the end of May, and kept abroad till October; then they must be placed in the green-house, and treated in the same way as other plants from the same country. It may also be propagated by cuttings, which may be planted during any of the summer months, on a bed of light earth, covering them close with either bell or hand-glasses, shading them from the sun, and gently refreshing them with water as the ground dries; when they have taken root, they must be hardened gradually, and then transplanted into small pots, and treated like the seedling plants.

P S O

The second sort was discovered by the late Dr. Houstoun at La Vera Cruz; this rises with a shrubby stalk three or four feet high, sending out a few side branches, which are garnished with oval trifoliate leaves which are hairy, standing upon slender foot-stalks. The flowers are collected in spikes at the end of the branches; they are of a purplish colour, and are succeeded by short pods, each containing one kidney-shaped seed. It is propagated by seeds, which must be sown upon a hot-bed, and the plants afterward treated in the same way as plants from hot countries; but as this is an abiding plant, so they must be removed into the stove in autumn, and kept in a moderate warmth in winter; and in summer they must have a large share of free air, but should constantly remain in the stove; the second year they will produce flowers, and sometimes their seeds will ripen in England.

The seeds of the third sort were brought me from Malabar; this is an annual plant, with trailing stalks about eight inches long, garnished with silvery leaves, composed of three or four pair of narrow lobes, terminated by an odd one. The flowers grow in small clusters at the wings of the leaves; they are small, and of a purple colour; the seed-pods are short, and have one small kidney-shaped seed in each. This is propagated by seeds, in the same manner as the second sort.

The fourth sort was discovered by the late Dr. Houstoun at Campeachy, where it grows naturally. This hath slender, shrubby, climbing stalks, which twine about any neighbouring support, and rise to the height of six or seven feet, garnished with winged leaves, composed of three pair of small, oval, obtuse lobes, terminated by an odd one. The flowers come out in small clusters from the wings of the leaves; they are small, of a bright blue colour, and are succeeded by short pods, including one kidney-shaped seed.

The fifth sort was discovered by the same gentleman, growing naturally at Campeachy. This rises with a shrubby stalk seven or eight feet high, sending out many long slender branches on every side, garnished with trifoliate leaves, whose lobes are small and wedge-shaped. The flowers are produced from the wings of the leaves in close small heads, standing upon pretty long foot-stalks; they are blue, and are succeeded by short pods, each containing a single kidney-shaped seed.

These two sorts are propagated by seeds, which must be sown upon a hot-bed; and when the plants come up, they must be treated in the same way as the third sort.

The sixth sort was discovered by the late Dr. Houstoun at La Vera Cruz; this is an annual plant, with a very branching herbaceous stalk, rising a foot and a half high, spreading wide on every side, garnished with winged leaves, composed of five or six pair of narrow wedge-shaped lobes, terminated by an odd one. The flowers are collected in close oblong spikes, terminating the branches; they are small, and of a bright blue colour, and are succeeded by short pods, each containing a single kidney-shaped seed. This is propagated by seeds, and requires the same treatment as the fourth sort.

The seventh sort grows naturally at La Vera Cruz, from whence the late Dr. Houstoun sent the seeds. This hath an upright shrubby stalk, which rises five or six feet high, having a few side branches, which are closely garnished with winged leaves, composed of three or four pair of small, roundish, hairy lobes, terminated by an odd one. The flowers are collected in small heads, coming out from the wings of the leaves, and at the end of the branches; they are yellow and red intermixed, and are succeeded by short pods, containing one kidney-shaped seed. This sort requires the same treatment as the third.

The eighth sort grows naturally in the south of France and Italy; the root of this is perennial, but the stalk is not of long duration, seldom lasting more than two

P T E

years; it rises about two feet high, sending out two or three slender branches, garnished with trifoliate leaves, whose lobes are oval, about two inches long, and one inch and a quarter broad, standing upon long foot-stalks; these, if handled, emit a strong scent of bitumen. The flowers are collected in heads, and have foot-stalks seven or eight inches long; they are blue, and are succeeded by short pods containing one seed.

The ninth sort grows naturally in Sicily, and also in Jamaica, from both which countries I have received the seeds. This has been supposed to be the same with the former, but I have many years propagated both by seeds, and have never found either of them vary. The leaves of this are much longer and narrower than those of the former sort, and are rounded at their base; the stalks are shrubby, and are of longer duration; the heads of the flowers are smaller, and the leaves have not so strong an odour. These are propagated by seeds, which should be sown on a bed of light earth in April, and in May the plants will come up, when they should be kept clean from weeds, and as soon as they are fit to remove they should be transplanted. Those of the eighth sort will live thro' the winter in the open air, if they are planted in a warm dry border; but the ninth sort requires some shelter in winter, so these should be planted in pots, and put into a common frame in winter, where they may be screened from hard frost. These plants flower from June to autumn, and perfect their seeds annually.

The tenth sort grows naturally in India; this is an annual plant; the stalks rise two feet high, and are garnished at each joint by one oval leaf about two inches long, and one inch and a half broad, having one strong midrib, from which come out several veins, which run toward the top of the leaf. The flowers stand upon long slender foot-stalks, which come out at the wings of the leaves; they are collected into small round heads, and are of a pale flesh colour. It flowers in July, and the seeds ripen in autumn. This is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be planted into separate small pots filled with light earth, and plunged into a moderate hot-bed of tanners bark, shading them from the sun till they have taken new root, after which they must have free air admitted to them in warm weather, and gently watered as often as they require it. When the plants have filled the pots with their roots, they should be removed into larger, and the beginning of July they may be removed into an airy glass-case, where they may be defended from cold, but should have free air in warm weather; with this care the plants will flower and ripen their seeds.

PSYLLIUM. See PLANTAGO.

PTRAMICA. See ACHILLEA.

PTELEA. Lin. Gen. Plant. 141. Shrub. Trefoil.

The CHARACTERS are,

The empalement of the flower is small, and cut into four acute segments. The flower has four oval spear-shaped petals, which spread open flat; it hath four awl-shaped stamina terminated by roundish summits, and an orbicular compressed germen, supporting a short style, crowned by two obtuse stigmas. The germen afterward becomes a roundish membranaceous capsule with two cells, each containing one obtuse seed.

This genus of plants is ranged in the first section of Linnæus's fourth class, which includes those plants whose flowers have four stamina and one style.

The SPECIES are,

1. PTELEA (*Trifoliata*) foliis ternatis. Lin. Sp. Plant. 118. *Ptelea with trifoliate leaves.* Frutex Virginianus trifolius, ulmi samaris. Pluk. Alm. 159. *Virginia Trefoil Shrub, with seeds like Elm, commonly called Carolina Shrub Trefoil.*

2. PTELEA (*Viscosa*) foliis simplicibus. Lin. Sp. Plant. 118. *Ptelea with single leaves.* Carpinus viscosa, salicis folio integro oblongo. Burm. Zeyl. 55. tab. 23. *Viscous Hornbeam with an entire oblong Willow leaf.* Plumier

mier has titled it *Staphylodendron Americanum foliis lauri angustis*. Cat. 18. *American Bladder Nut, with narrow Bay leaves*.

The first sort grows naturally in North America; it was first discovered in Virginia by Mr. Banister, who sent the seeds to England, from which some plants were raised at Fulham, and some other curious gardens; but being planted in the open air, they were destroyed by a severe winter, so that there were scarce any of the plants left in England. In 1724, Mr. Catesby sent over a good quantity of the seeds from Carolina, which succeeded so well as to furnish many gardens with the plants. This rises with an upright woody stem ten or twelve feet high, dividing upward into many branches, covered with a smooth grayish bark, garnished with trifoliate leaves standing upon long foot-stalks. The lobes are oval, spear-shaped, smooth, and of a bright green on their upper side, but pale on their under; these come out late in the spring, soon after which the bunches of flower-buds appear, which is generally in the beginning of June, the leaves being then but small, and afterward increase in their size, but are not fully grown till the flowers decay. The flowers are produced in large bunches at the end of the branches; they are of an herbaceous white colour, composed of four or five short petals, ending in acute points; these are fastened at their base to a short empalement, cut into four segments almost to the bottom. In the center is situated an orbicular compressed germen supporting a short style, which is attended by four awl-shaped stamina; the germen afterward turns to a capsule surrounded by a leafy border, having two cells, each containing one seed.

These shrubs may be propagated by cuttings, which should be planted in pots of fresh rich earth, and plunged into a moderate hot-bed. The best time for planting them is in the beginning of March, but they must be carefully managed so as not to have too much heat, and shaded from the sun in the middle of the day, otherwise they will not succeed. They may also be propagated by layers, but these are often two years before they take root; but if good seeds can be procured either here or from abroad, the plants raised from those will be much stronger than those which are propagated by either of the former methods.

These seeds may be sown in the beginning of April, on a bed of light earth, in a warm sheltered situation, where, if the ground is moistened in dry weather, the plants will come up in six weeks; but if the seeds are sown in pots, and placed on a very moderate hot-bed, the plants will come up sooner, and make greater progress the first year; but they must not be forced or drawn, for that will make them very tender; therefore in June the plants should be exposed to the open air, in a sheltered situation, where they may remain till the frost comes on, when those in the pots should be either placed under a common frame, to shelter them from severe frost, or the pots plunged into the ground, near a hedge, that the frost may be prevented from penetrating through the sides of the pots to the roots of the plants. The following spring the plants may be planted into a nursery-bed, at about one foot distance, where they may grow two years, by which time they will be fit to transplant where they are designed to remain.

These plants are a little tender while they are young, therefore will require some protection the first and second year, but particularly from the early frosts in autumn, which frequently kills the tops of the tender shoots before they are hardened; and the more vigorous the plants have grown the preceding summer, the greater danger there is of their being killed, therefore they should be screened either with mats or some other covering; but as they advance in strength, they become more hardy, and are rarely injured by frost.

The second sort grows naturally in both Indies; it is very common in most of the islands in the West-In-

dies. This sends up several stalks from the root, about the size of a man's arm, sending out several upright branches, covered with a light brown bark, which frequently separates from the wood, and hangs loose; they are garnished with stiff leaves, which vary greatly in their shape and size, some being four inches long, and an inch and a half broad; others are not three inches long, and a quarter of an inch broad; they are spear-shaped, entire, and of a light green, growing with their points upward, and have very short foot-stalks. The flowers are produced at the end of the branches in a sort of racemus, each standing upon a slender foot-stalk about an inch long; they have four solid channelled petals of an herbaceous colour, having four stamina which spread open, and in the center is situated a roundish compressed germen, which afterward turns to a compressed capsule with three cells, surrounded by a broad leafy border, each cell containing one or two roundish seeds.

This plant is propagated by seeds, which, if obtained fresh from abroad, will rise easily upon a hot-bed: when the plants are fit to remove, they should be each planted in a separate small pot filled with light loamy earth, and plunged into a hot-bed of tanners bark, shading them from the sun till they have taken new root; then they should have free air admitted to them every day in proportion to the warmth of the season, for they must not be drawn up weak, nor should they have too much water. In the autumn the plants must be removed into the stove, where they should have a temperate warmth in winter, but during that season little water should be given them; nor should they have too much heat, for either of these will soon destroy them: as the plants obtain strength, they will become more hardy, and may be set abroad in the open air for two or three months in the heat of summer, but it should be in a sheltered situation; in winter they must be placed in a stove, kept to a moderate temperature of warmth, for the plants will not live in a green-house here.

This was formerly shewn for the Tea-tree in many of the European gardens, where it many years passed for it among those who knew no better.

PULEGIUM. Raii Meth. Plant. 61. Mentha. Tourn. Inst. R. H. 189. Lin. Gen. Plant. 633. [This plant takes its name from *Pulex*, a flea; because being burnt, it is said to drive away fleas.] Pennyroyal, or Pudden-grass.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, cut into five parts. The flower is of the lip kind; it hath one petal with a short tube, divided at the brim into four parts; the helmet, or upper lip of the flower, is entire, the lower is cut into three equal segments. It hath four stamina, two being longer than the other, terminated by roundish summits, and a four-pointed germen, supporting an erect style, crowned by a bifid stigma. The germen afterward become four small seeds, sitting in the empalement of the flower.

This genus of plants is ranged in the second section of Mr. Ray's fourteenth class, which includes the herbs with whorled flowers which have scarce any helmet, but are cut into equal segments. Tournefort and Linnæus place this under the genus of *Mentha*, to which it may properly be joined; but as this is a title which has been long known in the shops and gardens, so I have chose to continue it.

The SPECIES are,

1. **PULEGIUM** (*Vulgare*) foliis ovatis obtusis, staminibus corollam æquantibus, caule repente. Pennyroyal with oval obtuse leaves, stamina equalling the petal, and a creeping stalk. *Pulegium latifolium*. C. B. P. Common or broad-leaved Pennyroyal.
2. **PULEGIUM** (*Erectum*) foliis lanceolatis, staminibus corollâ longioribus, caule erecto. Pennyroyal with spear-shaped leaves, stamina longer than the petal, and an upright stalk. *Pulegium Hispanicum erectum*, staminibus florum extantibus. Aët. Phil. London. Upright Spanish Pennyroyal, whose stamina stand out from the flowers.

3. *PULEGIUM* (*Cervinum*). foliis linearibus, floribus verticillatis terminalibusque. *Pennyroyal* with linear leaves, and flowers growing in whorls at the ends of the stalks. *Pulegium angustifolium*. C. B. P. *Narrow-leaved Pennyroyal*.

The first sort grows naturally upon moist commons, where the water stands in winter, in many parts of England. The root is fibrous and perennial; the stalks are smooth and trail upon the ground, putting out roots at every joint, whereby it spreads and propagates very fast; the stalks are garnished at each joint by two oval leaves, which are for the most part entire. The flowers grow toward the upper part of the branches, coming out just above the leaves at each joint, in whorls; they are of a pale purple colour, small and galeated, the helmet being entire; whereas in the Mint, this is indented at the point. The stamina of the flowers are of the same length with the petal, but the style is somewhat longer; the whole plant has a very strong smell, and a hot aromatic taste. There is a distilled water of this plant and also an oil, which is kept in the shops for medicinal use. There is a variety of this with a white flower, which is sometimes found growing naturally in England.

The seeds of the second sort were sent me from Gibraltar, which succeeded in the Chelsea Garden, but had been before introduced into several gardens, where it had been cultivated to supply the markets. The stalks of this grow erect and near a foot high; the leaves are longer and narrower than those of the common sort, the whorls of flowers are much larger, and their stamina are longer than the petals. This sort hath almost superseded the first in the markets, for as the stalks grow erect, so it is much easier to cut and tie in bunches than the common sort; it also comes earlier to flower, and has a brighter appearance, but whether it is as good for use, I shall leave to be determined by those whose province it belongs to.

The third sort grows naturally in the south of France and Italy, it is called Hart's Pennyroyal. This is by some preferred to the common sort for medicinal use; the stalks of this grow erect, near two feet high, sending out side branches all their length; the leaves are very narrow, and of a thicker substance than those of the common sort, the whorls of flowers are rather larger; the scent is not quite so strong as that of the first sort, and the stalks are frequently terminated by whorls of flowers. This is cultivated in gardens here, and flowers about the same time as the common sort. There is a variety of this with white flowers, which grows taller than that with purple flowers, but I do not believe it is a different sort. All these plants propagate themselves very fast by their branches trailing upon the ground, which emit roots at every joint, and fasten themselves into the earth, and send forth new branches; so that no more is required in their culture, than to cut off any of these rooted branches, and plant them out in fresh beds, allowing them at least a foot from plant to plant every way, that they may have room to grow; or the young shoots of these planted in the spring, will take root like Mint.

The best time for this work is in September, that the plants may be rooted before winter; for if the old roots are permitted to remain so close together, as they generally grow in the compass of a year, they are subject to rot in winter; besides the young plants will be much stronger, and produce a larger crop the succeeding summer, than if they were removed in the spring. These plants all love a moist strong soil, in which they will flourish exceedingly.

PULMONARIA. Tourn. Inst. R. H. 136. tab. 55. Lin. Gen. Plant. 184. [so called from Pulmones, Lat. the lungs, because supposed to be a very good medicament for the lungs.] *Lungwort*, in French, *Pulmonaire*.

The CHARACTERS are,
The flower hath a cylindrical, five-cornered, permanent

empalement of one leaf, cut into five segments at the top. The flower is of one petal, having a cylindrical tube the length of the empalement, cut at the top into five parts, which spread open, but the chaps are pervious. It hath five short stamina, terminated by erect summits which close together, and four germen supporting a short style, crowned by an obtuse indented stigma. The germen afterward turn to four roundish seeds, sitting in the bottom of the empalement.

This genus of plants is ranged in the first section of Linnæus's fifth class, which contains those plants whose flowers have five stamina and one style.

The SPECIES are,

1. *PULMONARIA* (*Officinalis*) foliis radicalibus ovato-cordatis scabris. Hort. Cliff. 44. *Lungwort* whose lower leaves are oval, heart-shaped, and rough. *Pulmonaria vulgaris*, maculoso folio. Clus. Hist. 169. *Common spotted Lungwort*, or *Jerusalem Cowslip*.
2. *PULMONARIA* (*Alpina*) foliis caulinis ovatis glabris, floribus patulis, segmentis obtusiusculis. *Lungwort* with oval smooth leaves to the stalks, spreading flowers, and obtuse segments. *Pulmonaria Alpina*, foliis molli-bus subrotundis, flore cæruleo. Tourn. Inst. R. H. 136. *Lungwort of the Alps*, with soft roundish leaves, and a blue flower.
3. *PULMONARIA* (*Saccharata*) foliis lanceolatis basi semi-amplexicaulibus, calycibus abbreviatis. *Lungwort* with spear-shaped leaves, whose base half embrace the stalk, and the empalement shorter than the tube of the flower. *Pulmonaria maxima* foliis quasi saccharo incrustatis. Pluk. Alm. 359. *Greatest Lungwort* with spotted leaves, as if they were incrustated with sugar.
4. *PULMONARIA* (*Angustifolia*) foliis radicalibus lanceolatis. Hort. Cliff. 44. *Lungwort* with the lower leaves spear-shaped. *Pulmonaria angustifolia* cæruleo flore. J. B. 3. 596. *Narrow-leaved Lungwort* with a blue flower.
5. *PULMONARIA* (*Orientalis*) caulibus procumbentibus, floribus singularibus alaribus, calycibus inflatis corollâ longioribus. *Lungwort* with trailing stalks, flowers growing singly from the sides, and swollen empalements which are longer than the petals. *Pulmonaria Orientalis*, calyce velicario, foliis cœlii, flore purpureo infundibuliformi. Tourn. Cor. 6. *Eastern Lungwort* with an empalement like a bladder, a Viper's Bugle's leaf, and a purple funnel-shaped flower.
6. *PULMONARIA* (*Virginica*) calycibus abbreviatis, foliis lanceolatis obtusiusculis. Lin. Sp. Plant. 135. *Lungwort* with short empalements to the flowers, and spear-shaped obtuse leaves. *Symphytum five pulmonaria non maculata*, foliis glabris acuminatis flore patulo cæruleo. Pluk. Alm. 359. *Lungwort* with smooth, unspotted, acute-pointed leaves, and a blue spreading flower.

The first sort grows naturally in woods and shady places in Italy and Germany, and is cultivated in the English gardens chiefly for medicinal use. It hath a perennial fibrous root; the lower leaves are rough, of an oval heart-shape, about six inches long, and two inches and a half broad, of a dark green on their upper side, marked with many broad whitish spots, but pale and unspotted on their under side; the stalks rise almost a foot high, having several smaller leaves on them, standing alternately. The flowers are produced in small bunches at the top of the stalks, each having a tubulous hairy empalement as long as the tube of the flower; the brims of the petal are spread open, and are shaped like a cup; these are red, purple, and blue, in the same bunch. They appear in April, and are succeeded by four naked seeds, which ripen in the empalement. It is accounted a pectoral balsamic plant, and good for coughs and consumptions, spitting of blood, and the like disorders of the lungs; it is likewise put into wound drinks.

The second sort grows naturally on the Alps; this hath a perennial fibrous root; the leaves are large, smooth, and spotted on their upper side; the stalks rise nine inches high, and are garnished with oval leaves whose base join the stalks. The flowers grow in small bunches on the top of the stalk; they are purple, and spread open wider than those of the common sort.

The third fort grows naturally upon the Helvetian Mountains; this is a perennial plant, whose leaves are large, spear-shaped, and rough. The foot-stalks of the lower leaves are broad; the stalks rise a foot high, and are garnished with spear-shaped leaves, whose base half embrace the stalks; the leaves are greatly spotted with white, appearing as if they were incruited with sugar-candy; the flowers grow in large bunches on the top of the stalk; their tubes are longer than the empalement, and their brims are spread more than those of the common fort. They are of a bright blue, and appear in April and May.

The fourth fort grows naturally in Aultria and Hungary; this hath leaves much narrower than those of the common fort, which are covered with soft hairs. The stalks rise a foot high, and are garnished with narrow leaves of the same shape with those below, but smaller; these almost embrace the stalk with their base. The flowers are produced in bunches on the top of the stalks like the others; these appear of a red colour before they expand, but when they are fully blown, are of a most beautiful blue colour. This fort flowers early in the spring, but is very rare in England at present.

The fifth fort was discovered in the Archipelago by Dr. Tournefort, who sent the seeds to the Royal Garden at Paris; this is an annual plant. The lower leaves are oblong and hairy; the stalks trail upon the ground, and are a foot and a half long, garnished with oblong hairy leaves sitting close to the stalks; just above each leaf comes a single flower of a full purple colour, funnel-shaped, the brims not spreading; the empalement is swollen like an inflated bladder, and covers the petal of the flower, so as not to be seen without a near inspection. This plant flowers in May, if the plants come up in autumn, and after the flowers are past, the four seeds ripen in the empalement.

The sixth fort grows naturally upon mountains in most parts of North America. The seeds of this plant were sent many years since by Mr. Banister from Virginia, and some of the plants were raised in the gardens of the Bishop of London, at Fulham, where for several years it was growing, and was communicated to several other curious gardens; this hath a thick, fleshy, perennial root, sending out many small fibres. The stalks rise a foot and a half high, and divide at the top into several short branches; the leaves which are near the root are four or five inches long, and two inches and a half broad; they are smooth, obtuse, and of a light green, having short foot-stalks; those upon the stalk diminish in their size upward, but are of the same shape, and sit close to the stalk. Each of the small branches at the top of the stalk is terminated by a cluster of flowers, each standing upon a separate short foot-stalk; their empalements are very short, and are cut into five segments almost to the bottom; the tube of the flower is long, and at the top spreads open in shape of a funnel, the brim being entire, but appears five-cornered from the folding of the petal. The most common colour of these flowers is blue, but there are some purple, others red, and some white. They appear in April, and, if they have a shady situation, will continue in beauty great part of May, and sometimes they are succeeded by seeds in England. The leaves and stalks entirely decay in August, and the roots remain naked till the following spring.

There are some other species of this genus, which are preserved in botanic gardens for the sake of variety, but, having little beauty, they are seldom cultivated in other places.

The first, second, third, fifth, and sixth forts have perennial roots, so may be cultivated by parting of their roots, which may be done either in the spring, or autumn; but if the ground be moist into which they are planted, it is better to be done in the spring, otherwise the autumn is the more preferable season, that the plants may be well rooted before the dry wea-

ther comes on in the spring, which will cause them to flower much stronger.

The soil in which they are planted should not be rich, but rather a fresh light sandy ground, in which they will thrive much better than in a richer soil, in which they are very subject to rot in the winter. They should have a shady situation, and the first and third forts thrive best in a moist soil, for in a hot dry soil they burn and decay in summer, unless they are duly watered in dry weather. All these early forts are better transplanted, and parted in autumn, that they may be well rooted to flower strong the following spring. The sixth fort should not have a soil too moist, for as the roots run deep in the ground, they will be in danger of rotting by much wet.

The other fort is annual, and propagated by seeds only. The best time to sow these is in autumn, soon after they are ripe, for the plants will resist the cold of our winters very well, so will flower early the following summer, and good seeds may be obtained; whereas those which are sown in the spring sometimes miscarry, or lie a year in the ground. These seeds should be sown where they are designed to remain, for the plants do not succeed very well when they are transplanted. When the plants come up, they require no other culture but to keep them clear from weeds; and, where they are too close, to thin them. If these plants are permitted to scatter their seeds, the plants will come up better than when they are sown.

PULSATILLA. Tourn. Inst. R. H. 284. tab. 148. Anemone. Lin. Gen. Plant. 614. [so called of Pulsando, Lat. because the seeds of this plant are blown, and fly away with the least wind.] Pasque-flower; in French, *Coquelourde*.

The CHARACTERS are,

The flower hath a leafy involucre ending in many points; it hath two orders of petals, three in each which are oblong and pointed, and a great number of slender stamina about half the length of the petals, terminated by erect twin summits, and a great number of germen collected in a head, with acute styles crowned by obtuse stigmas. The germen afterward become so many seeds, having long hairy tails sitting upon the oblong receptacle.

This genus of plants is ranged in the seventh section of Linnæus's thirteenth class, which includes those plants whose flowers have many stamina and styles, and joins this genus to the Anemone in the later editions of his works.

The SPECIES are,

1. PULSATILLA (*Vulgaris*) foliis decompositis pinnatis, flore nutante, limbo erecto. Hort. Cliff. 223. *Pasque-flower with decomposed winged leaves, and a nodding flower having an erect rim.* Pulsatilla folio crassiore & majore flore. C. B. P. 177. *Pasque-flower with a thicker leaf, and a larger flower.*
2. PULSATILLA (*Pratenfis*) foliis decompositis pinnatis, flore pendulo, limbo reflexo. Hort. Cliff. 223. *Pasque-flower with decomposed winged leaves, and a pendulous flower whose border is reflexed.* Pulsatilla flore minore nigricante. C. B. P. 177. *Pasque-flower with a smaller darkish flower.*
3. PULSATILLA (*Vernalis*) foliis simpliciter pinnatis, foliolis lobatis, flore erecto. Flor. Suec. 448. *Pasque-flower with simple winged leaves, whose wings have lobes and an erect flower.* Pulsatilla lutea apii hortensis folio. C. B. P. 177. *Yellow Pasque-flower with a Parsley leaf.*
4. PULSATILLA (*Patens*) foliis digitatis multifidis, flore erecto patente. *Pasque-flower with hand-shaped leaves having many points, and an erect spreading flower.* Pulsatilla anemones folio dissecto lanuginosa, flore majore dilute luteo patente. Amman. Ruth. 104. *Pasque-flower with a cut Anemone leaf which is downy, and a larger pale, yellow spreading flower.*

The first of these plants is common in divers parts of England; it grows in great plenty on Gogmagog-hills on the left-hand of the highway leading from Cambridge to Haveril, just on the top of the hill; also about

P U L

about Hildersham, six miles from Cambridge, and on Bernack Heath not far from Stamford, and on Southrop Common adjoining thereto; also on mountainous and dry pastures just by Leadstone Hall near Pontefract in Yorkshire. It flowers in April.

This hath a fleshy taper root which runs deep in the ground; the leaves are hairy, and finely cut, like those of the wild Carrot, and spread near the ground; the stalk rises near a foot high, is pretty thick and hairy, and naked at the top, where there is a leafy involucre to the flower, which is hairy, ending in many points; it is terminated by one flower composed of six petals ranged in two orders, three without, and three within; they are oblong, thick, and of a bright purple colour; they form a sort of bell-shaped flower nodding on one side, and their points turn upward. Within the petals are a great number of slender yellowish stamina terminated by erect summits, and in the center a great number of germen are collected in a head, which afterward become seeds, each having a long tail, by which they are distinguished from Anemone.

There is a variety of this with double, and another with white flowers, but these have been obtained from seeds of the other.

The second sort hath shorter leaves than the first; the stalks do not rise so high; the flowers do not expand so wide, and hang downward, but their brims are reflexed; they are of a very dark purple colour. This grows naturally in the meadows in Germany.

The third sort grows naturally on the Alps and Helvetian Mountains; this hath a perennial root. The leaves are like those of Smallage, and are simply winged; the stalk rises near a foot high, is naked almost to the top, where comes out a neat hairy involucre, and above that one yellow flower shaped like the perennial yellow Adonis, standing erect. These appear about the same time with the former, and are succeeded by seeds which ripen at Midsummer.

The fourth sort grows in Siberia; this hath a thick fleshy root which sends out many strong fibres. The leaves are hand-shaped, composed of several roundish lobes, like some of the sorts of Ranunculi; they are downy, and cut into several segments. The stalk rises nine or ten inches high, having a hairy involucre a considerable distance below the flower; it is terminated by one flower, which is large, spreading, and of a whitish yellow colour, with deep yellow stamina. This flowers early in the spring.

There are some other species of this plant, but those here mentioned are all the sorts which I have seen growing in England, and therefore I have not enumerated more, as it would be to little purpose, since it is difficult to procure them from the countries where they naturally grow.

These plants may be propagated by seeds, which should be sown in boxes or pots filled with very light sandy earth, observing not to cover the seeds too deep with mould, which will prevent their rising, for they require no more than just to be covered. These boxes should be placed where they may have the morning sun until ten of the clock, but must be screened from it in the heat of the day; and, if the season proves dry, the earth should be often refreshed with water. The best time for sowing of these seeds is in July or August, soon after they are ripe, for if they are kept till spring, they seldom grow.

These boxes or pots, in which the seeds are sown, should remain in this shady situation until the beginning of October, when they should be moved where they may enjoy the full sun during the winter season. About the beginning of March the plants will begin to appear, at which time the boxes should be again removed where they may have only the forenoon sun; for if they are too much exposed to the heat, the young plants will soon be destroyed. They should also be refreshed with water in dry weather, which will greatly promote their growth, and should be carefully kept clean from weeds, which, if suf-

P U N

fered to grow among them, will in a short time overbear them.

When the leaves of this plant are entirely decayed (which is commonly in July,) you should then take up all the roots, which being nearly of the colour of the ground, will be difficult to find while small; therefore you should pass the earth through a fine wire sieve, which is the best method to separate the roots from the earth, (but notwithstanding all possible care taken, yet there will be many small roots left; so that the earth should either be put into the boxes again, or spread upon a bed of light earth, to see what plants will arise out of it the succeeding year.) The roots being taken up, should be immediately planted again on beds of light, fresh, sandy earth, about three or four inches asunder, covering them about three inches thick with the same light earth. The spring following most of these plants will produce flowers, but they will not be so large and fair as in the succeeding years, when the roots are larger.

The roots of these plants generally run down deep in the ground, and are of a fleshy substance, somewhat like Carrots, so will not bear to be kept long out of the ground; therefore, when they are removed, it should be done early in the autumn, that they may take fresh root before the frost comes on; for if they are transplanted in the spring, they will not produce strong flowers. These plants thrive best in a loamy soil, for in very light dry ground they are apt to decay in summer.

PUMPKION. See PEPO.

PUNICA. Tourn. Inst. R. H. 633. tab. 407. Lin. Gen. Plant. 544. [This plant takes its name from its punicean or red appearance, for its flowers and fruit are of that colour. It is called Granatum, from the word Granis, because the fruit has many grains; or, as some suppose, of Granata, or Granada, because it grows in great plenty in that country.] The Pomegranate-tree; in French, *Grenadier*.

The CHARACTERS are,

The empalement of the flower is permanent, bell-shaped, coloured, and of one leaf, cut into six parts at the top. The flower has five roundish, erect, spreading petals which are inserted in the empalement, and a great number of slender stamina, which are also inserted in the empalement, terminated by oblong summits. The germen is situated under the flower, supporting a single style crowned by a headed stigma; it afterward becomes a large almost globular fruit, crowned by the empalement. The fruit is divided into several cells by membranous partitions, which are filled with roundish succulent seeds.

This genus of plants is ranged in the first section of Linnaeus's twelfth class, in which he places those plants whose flowers have more than twenty stamina, which are inserted either in the petals or empalement, and one style.

The SPECIES are,

1. PUNICA (*Granatum*) foliis lanceolatis, caule arboreo. Hort. Cliff. 134. *Pomegranate with linear spear-shaped leaves, and a tree-like stalk.* Punica quæ malum granatum fert. Cæsalp. Punica which bears the Pomegranate
2. PUNICA (*Nana*) foliis linearibus, caule fruticoso. *Pomegranate with linear leaves; and a shrubby stalk.* Punica Americana, nana seu humillima. Lig. Tourn. Inst. 636. *The American Dwarf Pomegranate.*

There are the following varieties of the first sort, which are supposed to be accidental variations obtained by culture from the seeds, therefore I have not enumerated them as species; but as many curious persons will expect to find them inserted here, I shall just mention them.

The wild Pomegranate with single and double flowers.

The sweet Pomegranate.

The small flowering Pomegranate with single and double flowers.

The Pomegranate with striped flowers.

These plants grow naturally in Spain, Portugal, Italy, and Mauritania. There are also many of them in

P U N

in the West-Indies, but they are supposed to have been transplanted there from Europe; but they are so much improved there, as to be much preferable to any in Europe, the fruit being larger and finer flavoured.

This tree rises with a woody stem eighteen or twenty feet high, sending out branches the whole length, which likewise put out many slender twigs, so as to render them very thick and bushy. Some of these are armed with sharp thorns; they are garnished with spear-shaped leaves about three inches long, and half an inch broad in the middle, drawing to a point at each end; they are of a light lucid green, and stand opposite. The flowers come out at the end of the branches, sometimes singly, and at others three or four together; one of the largest terminates the branch, and immediately under that are two or three smaller buds, which, after the flower is past, swell larger and expand, whereby there is a continued succession of flowers for some months. The empalement of the flower is very thick, fleshy, and of one piece, cut at the top into five segments; it is of a fine red colour, and within are included five in the single flowers, but in the double a great number of scarlet petals, which are inserted in the empalement. In the center is situated the style, arising from the germen, encompassed by many slender stamina, which are terminated by oblong yellowish summits. After the flower decays, the germen swells to a roundish fruit crowned by the empalement, having a hard shell, including a pulp filled with angular seeds. This tree flowers in July, August, and September, and the fruit ripens late in autumn.

The Balaustia of the shops is the empalement of the flower of the double flowering Pomegranate.

The first of these trees is now pretty common in the English gardens, where formerly it was nursed up in cases, and preserved in green-houses with great care (as was also the double flowering kind;) but they are both hardy enough to resist the severest cold of our climate in the open air; and, if planted against warm walls in a good situation, the first sort will often produce fruit, which in warm seasons will ripen tolerably well; but as these fruits do not ripen till late in the autumn, they are seldom well tasted in England, for which reason the sort with double flowers is commonly preferred to it. The sort with sweet fruit, as also the wild sort, are less common in the English gardens than the former two.

These plants may be easily propagated by laying down their branches in the spring, which in one year's time will take good root, and may then be transplanted where they are designed to remain. The best season for transplanting of these trees is in spring, just before they begin to shoot; they should have a strong rich soil, in which they flower much better, and produce more fruit than if planted on dry poor ground; but in order to obtain these in plenty, there should be care taken in the pruning of these trees, for want of which we often see these trees very full of small shoots, but do not find many flowers produced upon them; therefore I shall set down directions for pruning of these trees, so as to obtain a great quantity of flowers and fruit.

The flowers of this tree, always proceed from the extremity of the branches which are produced the same year. This therefore directs, that all weak branches of the former year should be cut out, and that the stronger should be shortened in proportion to their strength, in order to obtain new shoots in every part of the tree. The branches may be laid in against the wall about four or five inches asunder; for, as their leaves are small, there is not a necessity of allowing them a greater distance. The best time for this work is about Michaelmas, or a little later, according to the mildness of the season, for if they are left until spring before they are pruned, they seldom put out their shoots so early, and the earlier they come cut, the sooner the flowers will appear, which is of great consequence where fruit is desired. In summer

P Y R

they will require no other dressing, but to cut off all vigorous shoots which grow from the wall, and never produce flowers (for it is the middling shoots only which are fruitful;) and when the fruit is formed, the branches on which they grow should be fastened to the wall to support them, otherwise the weight of the fruit, when grown large, will be apt to break them down.

Though, as I said before, the fruit of this tree seldom arrives to any perfection in this country, so as to render it valuable; yet, for the beauty of its scarlet-coloured flowers, together with the variety of its fruit, there should be one tree planted in every good garden, since the culture is not great which they require; the chief care is to plant them upon a rich strong soil, and in a warm situation. Upon some trees which had these advantages, I have obtained a great quantity of fruit which have arrived to their full magnitude, but I cannot say they were well flavoured; however, they made a very handsome appearance upon the trees.

The double flowering kind is much more esteemed than the other in this country for the sake of its large, fine, double flowers, which are of a most beautiful scarlet colour; and, if the trees are supplied with nourishment, will continue to produce flowers for two months successively, which renders it one of the most valuable flowering trees yet known. This must be pruned and managed in the same manner as hath been already directed for the fruit-bearing kind, but this sort may be rendered more productive of its beautiful flowers by grafting it upon stocks of the single kind, which will check the luxuriancy of the trees, and cause them to produce flowers upon almost every shoot; by which method I have had a low tree, which was planted in the open air, extremely full of flowers, which made a very fine appearance.

The second sort grows naturally in the West-Indies, where the inhabitants plant it in their gardens to form hedges. It seldom rises more than five or six feet high in those countries, so may be kept within compass, and there the plants continue flowering great part of the year. The flowers of this kind are much smaller than those of the common sort; the leaves are shorter and narrower, and the fruit is not larger than a Nutmeg, and has little flavour, so it is chiefly propagated for the beauty of its flowers. This is undoubtedly a distinct species from the common sort, and is much tenderer.

This plant may be propagated by layers in the same manner as the former sorts, but must be planted in pots filled with rich earth, and preserved in a green-house, otherwise it is too tender to endure the cold of our winters; and in the summer, when the flowers begin to appear, if the plants are exposed to the open air, the buds will fall off, and never open; so that they should not be exposed to the open air, but placed in an airy glass-case, giving them a large share of air every day in mild weather. As they will be covered at the top by the glasses, the flowers will expand, and the fruit will grow to the full size in England with this management, though they are not very desirable; but hereby the plants may be continued in flower upward of two months, and will make a fine appearance.

PURSLAIN. See PORTULACA.

PYRACANTHA. See MESPILUS.

PYROLA. Tourn. Inst. R. H. 256. tab. 132. Lin. Gen. Plant. 490. Winter-green.

The CHARACTERS are,

The flower hath a small permanent empalement cut into five segments; it hath five roundish, concave, spreading petals, and ten awl-shaped stamina terminated by large nodding summits with two rising horns, and a roundish germen supporting a slender style, which is permanent and longer than the stamina, crowned by a thick stigma. The germen afterwards becomes a roundish, depressed, five-cornered capsule, with five cells opening at the angles, filled with seeds.

This

P Y R

This genus of plants is ranged in the first section of Linnaeus's tenth class, which contains those plants whose flowers have ten stamina and one style.

The SPECIES are,

1. PYROLA (*Rotundifolia*) staminibus adscendentibus, pistillo declinato. Flor. Suec. 330. *Winter-green with rising stamina, and a declining pointal.* Pyrola rotundifolia major. C. B. P. 191. *Greater round-leaved Winter-green.*
2. PYROLA (*Secunda*) racemo unilaterali. Flor. Suec. 332. *Winter-green with a bunch of flowers ranged on one side the foot-stalk.* Pyrola folio mucronato serrato. C. B. P. 191. *Winter-green with a sawed pointed leaf.*
3. PYROLA (*Uniflora*) scapo unifloro. Flor. Lapp. 167. *Winter-green with one flower in a sheath.* Pyrola rotundifolia minor. C. B. P. 191. *Smaller round-leaved Winter-green.*
4. PYROLA (*Maculata*) pedunculis bifloris. Lin. Sp. Plant. 396. *Winter-green with two flowers on a foot-stalk.* Pyrola Marylandica minor, folio mucronato arbuti. Pet. Mus. 675. *Smaller Winter-green of Maryland, with a pointed Strawberry leaf.*

The first sort grows wild in many places in the North of England, particularly near Halifax in Yorkshire, on rocky hills and heaths, as also in shady woods; so it is very difficult to preserve in gardens in the southern parts.

This hath a perennial root, from which spring out five or six roundish leaves, about an inch and a half long, and almost as broad, of a thick consistence, of a deep lucid green, and entire, standing upon pretty long foot-stalks. Between these rise a slender upright stalk near a foot high, naked great part of the length, ending in a loose spike of flowers, which are composed of five large concave petals, spreading like a Rose, but the two upper leaves are formed into a kind of helmet. In the center is situated a crooked pointal, bending downward, attended by ten slender stamina, terminated by Saffron-coloured summits. It flowers in July, and the flowers are succeeded by cornered compressed capsules, having five cells, filled with small seeds.

The second sort grows naturally upon mountains in Italy, particularly near Verona and Genoa, and I have found it growing in Westmoreland. This hath a slender, creeping, perennial root, from which arise two or three very slender ligneous stalks about five inches high, sustaining at the top four or five oval acute-pointed leaves, an inch and a half long, and one broad, of a thinner consistence, and a brighter green than those of the former, each standing upon a short foot-stalk; and between these, on the side of the stalk, comes out the foot-stalk of the flowers, upon which they are ranged along one side; they are shaped like the other, but are smaller, as are also the capsules. It flowers about the same time with the first sort.

The third sort grows naturally in shady woods in the northern parts of Europe. This hath a perennial creeping root, from which come forth four or five roundish leaves of a pretty thick consistence, and between these arises a foot-stalk about four inches high, sustaining one large white flower on the top, of the same shape as the others. It flowers in June.

The fourth sort grows naturally in North America; this hath a ligneous perennial root, from which arise two or three ligneous stalks a foot and a half high, garnished with stiff leaves two or three inches long, one broad near the base, ending in acute points, and have some sharp indentures on their borders; the midrib is remarkably broad, and very white, as are also the veins which run from it. The flowers are produced at the end of the stalk on slender foot-stalks about three inches long, each sustaining two small pale-coloured flowers at the top. It flowers in June. These are all of them very difficult to cultivate in gardens, for as they grow on very cold hills, and in mossy moorish soil, when they are removed to a better soil, and in a warmer situation, they seldom continue long. The best time to transplant these plants into gardens is about Michaelmas, provided the roots can then be found, when they should be taken up with balls of

P Y R

earth to their roots, and planted in a shady situation; and on a moist undunged soil, where they should be frequently watered in dry weather, otherwise they will not thrive. Some of these plants may be planted in pots, which should be filled with earth as nearly resembling that in which they naturally grow as possible, and place them in a shady situation, where, if they are constantly watered in dry weather, they will thrive very well.

The first sort is ordered by the College of Physicians to be used in medicine, and is generally brought over from Switzerland amongst other vulnerary plants, amongst which class this plant is ranged; and by some hath been greatly commended.

PYRUS. Tourn. Inst. R. H. 628. tab. 404. Lin. Gen. Plant. 550. The Pear-tree; in French, *Poirier*.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is concave, and divided into five parts at the top; it hath five roundish concave petals, which are inserted in the empalement, and many awl-shaped stamina shorter than the petals, which are also inserted in the empalement, and terminated by single summits. The germen is situated under the flower, supporting four or five styles crowned by single stigmas; it afterward becomes a pyramidal fleshy fruit indented at the top, but produced at the base, having five membranaceous cells, each containing one smooth oblong seed pointed at the base.

This genus of plants is ranged in the fourth section of Linnaeus's twelfth class, which includes those plants whose flowers have more than twenty stamina inserted in the empalement, and five styles. To this genus he has joined the Malus and Cydonia.

The Pear and Quince may be joined together with more propriety than the Apple with either, for the fruit of the the two former are produced at their base, whereas the Apple is indented both at the top and bottom; nor will the Apple grow upon either of the other two, or they upon the Apple, when grafted or budded; but the Quince and Pear will grow upon each other, so there is a boundary set by nature between those and the Apple. The several varieties of Pears, which are now cultivated in the curious fruit-gardens, have been accidentally obtained by seeds, so must not be deemed distinct species; but, as they are generally distinguished in the fruit-gardens and nursery, by the shape, size, and flavour of their fruit, I shall continue those distinctions, that the work may not appear imperfect to such as delight in the cultivation of these fruits.

The SPECIES are,

1. PYRUS (*Musk*) sativa, fructu æstivo parvo racemoso odoratissimo. Tourn. *Petit Muscat, i. e. Little Musk Pear, commonly called the Supreme.* This fruit is generally produced in large clusters; it is rather round than long, the stalk short; and, when ripe, the skin is of a yellow colour; the juice is somewhat musky, and, if gathered before it is too ripe, is a good Pear. This ripens the middle of July, and will continue good but for a few days.
2. PYRUS (*Chio*) sativa, fructu æstivo minimo odoratissimo. Tourn. *Poire de Chio, i. e. the Chio Pear, commonly called the little Bastard Musk Pear.* This is smaller than the former, but is in shape pretty much like that. The skin, when ripe, has a few streaks of red on the side next the sun, and the fruit seldom hangs in clusters as the former, but in other respects is nearly like it.
3. PYRUS (*Citron des Carmes*) sativa, fructu æstivo parvo, è viridi albido. Tourn. *Poire Hâtiveau, i. e. the Hasting Pear; Poire Madeleine, ou Citron des Carmes, called commonly the green Chisel.* This is a larger Pear than either of the former, and is produced more toward the pedicle. The skin is thin, and of a whitish green colour when ripe; the flesh is melting, and, if not too ripe, of a sugary flavour, but is apt to be mealy. This ripens in the end of July.
4. PYRUS (*Muscadelle*) sativa, fructu æstivo partim saturatè rubente, partim flavescente. Tourn. *Muscadelles Rouges, i. e. the red Muscadelle.* It is also called *La Bellissime, i. e. the Fairest or Supreme.* This is a large early Pear, of great beauty; the skin is of a fine yellow

yellow colour, when ripe, beautifully striped with red; the flesh is half melting, and has a rich flavour, if gathered before it be too ripe, but it is apt to be mealy. This generally produces two crops of fruit in a year; the first is commonly ripe about the end of July, and the second ripens in September, but this late crop is seldom well tasted.

5. PYRUS (*Muscat*) sativa, fructu æstivo parvo flavescence moschato. Tourn. Petit Muscat, i. e. *the Little Muscat*. This is a small Pear, rather round than long; the skin is very thin, and, when ripe, of a yellowish colour; the flesh is melting, and of a rich musky flavour, but will not keep long when ripe. This comes the end of July.
6. PYRUS (*Cuisse Madame*) sativa, fructu æstivo oblongo ferrugineo, carne tenerâ moschatâ. Tourn. *Cuisse Madame, Lady's Thigh, in England commonly called Jargonelle*. This is a very long Pear, of a pyramidal shape, having a long foot-stalk; the skin is pretty thick, of a russet green colour from the sun, but towards the sun it is inclined to an iron colour; the flesh is breaking, and has a rich musky flavour; ripe the beginning of August. This is one of the best early summer Pears yet known, and is certainly what all the French gardeners call the Cuisse Madame, as may be easily observed by their description of this Pear; but I suppose the titles of this and the Jargonelle were changed in coming to England, and have been continued by the same names.
7. PYRUS (*Windsor*) sativa, fructu oblongo, è viridi flavescence. *The Windsor Pear*. This is an oblong fruit, which swells toward the crown, but near the stalk is drawn toward a point; the skin is smooth, and, when ripe, of a yellowish green colour; the flesh is very soft, and, if permitted to hang but two or three days after it is ripe, grows mealy, and is good for nothing.
8. PYRUS (*Jargonelle*) sativa, fructu æstivo oblongo, è viridi albo. *The Jargonelle, now commonly called Cuisse Madame*. This is certainly what the French gardeners call the Jargonelle, which, as I have before observed, is now in England, given to another fruit much preferable to this, so that the two names are changed; for the Jargonelle is always placed amongst those which the French call bad fruit, and the Cuisse Madame is set down amongst their best fruit, which is certainly the reverse with us, as they are now named. This Pear is somewhat like the Windsor, but is not so swelling toward the crown, and is smaller toward the stalk; the skin is smooth, of a pale green colour; the flesh is apt to be mealy if it stands to be ripe, but, being a plentiful bearer, is much propagated for the London markets.
9. PYRUS (*Orange Musk*) sativa, fructu æstivo globoso sessili moschato, maculis nigris consperso. Tourn. *Orange Mosquée, i. e. the Orange Musk*. This is a middle-sized Pear, of a short globular form; the skin is of a yellowish colour, spotted with black; the flesh is musky, but is very apt to be a little dry and choaky. It ripens in August.
10. PYRUS (*Blanquet*) sativa, fructu æstivo albido majori. Tourn. *Gros Blanquet, i. e. Great Blanket*. This is also called La Muffette d'Anjou, i. e. the Bagpipe of Anjou. It is a large Pear approaching to a round form; the skin is smooth, and of a pale green colour; the flesh is soft, and full of juice, which hath a rich flavour; the stalk is short, thick, and spotted; the wood is slender, and the leaf is very much like that of the tree called the Jargonelle. This ripens the beginning of August.
11. PYRUS (*Musk Blanquet*) sativa, fructu æstivo albido saccharato odoratissimo. Tourn. *The Blanquette, or Musk Blanquette; the little Blanket Pear*. This Pear is much less than the former, and more pinched in near the stalk, which is also short, but slenderer than that of the former; the skin is soft, and of a pale green colour; the flesh is tender, and full of a rich musky juice; the wood of this tree is much stronger than that of the former, and the shoots are commonly shorter. This ripens the middle of August.

12. PYRUS (*Long-stalk Blanquet*) sativa, fructu æstivo albido, pediculo longo donato. Tourn. *Blanquette à longue queue, i. e. Long-stalked Blanket Pear*. This Pear is in shape somewhat like the former, but the eye is larger, and more hollow at the crown; toward the stalk it is somewhat plumper, and a little crooked; the skin is very smooth, white, and sometimes toward the sun is a little coloured; the flesh is between melting and breaking, and is full of a rich sugary juice. This ripens the middle of August.
13. PYRUS (*Skinless*) sativa, fructu æstivo oblongo rufescente saccharato. Tourn. *Poire sans Peau, i. e. the Skinless Pear*. It is also called Fleur de Guigne, i. e. Flower of Guigne; and by some, Roufflet hâtif, i. e. the early Russet. This is a middle-sized fruit, of a long shape, and a reddish colour, somewhat like the Russet; the skin is extremely thin; the flesh is melting, and full of a rich sugary juice; the shoots are long and strait. This ripens the middle of August.
14. PYRUS (*Robine*) sativa, fructu æstivo turbinato, carne tenera saccharato. *Muscat Robine, i. e. the Musk Robine Pear*. This is also called Poire à la Reine, i. e. the Queen's Pear; Poire d'Ambre, i. e. the Amber Pear; and Pucelle de Xaintonge, i. e. the Virgin of Xaintonge. This is a small round Pear, of a yellowish colour when ripe; the flesh is between melting and breaking. It hath a rich musky flavour, and is a great bearer; it ripens the middle of August.
15. PYRUS (*Drone*) sativa, fructu æstivo turbinato moschato. *Le Bourdon Mosque, i. e. the Musk Drone Pear*. This is a middle-sized round fruit, whose skin is of a yellowish colour when ripe; the flesh is melting, and has a high musky juice, but it must not hang too long on the tree, for it is subject to grow mealy in a short time. This ripens the end of August.
16. PYRUS (*Orange*) sativa, fructu æstivo globoso sessili, è viridi purpurascence saccharato odorato. Tourn. *Orange Rouge, i. e. the red Orange Pear*. This Pear hath been the most common of all the sorts in France, which was occasioned by the general esteem it was in some years since. This is a middle-sized round fruit, of a greenish colour, but the side next the sun changes to a purple colour when ripe; the flesh is melting, and the juice is sugared with a little perfume; the eye is very hollow, and the stalk is short. This ripens the end of August.
17. PYRUS (*Cassiolette*) sativa, fructu æstivo oblongo minori cinereo odorato. Tourn. *Cassiolette Friolet, Muscat Verd Lechevrien*. This is so called from its being shaped like a perfuming-pot. It is a long fruit, in shape like the Cuisse Madame, of an Ash colour; its flesh is melting, and full of a perfumed juice, but it is very apt to rot in the middle as soon as ripe, otherwise it would be esteemed an excellent Pear. It is ripe the end of August.
18. PYRUS (*Orange Musk*) sativa, fructu æstivo turbinato è viridi albido. *Orange Musquée, i. e. the Musk Orange Pear*. This is a large round Pear, in shape like a Bergamot; the skin is green, and the flesh is melting, but it is very subject to rot upon the tree, which renders it not near so valuable as some others. It ripens the end of August.
19. PYRUS (*Oignonnet*) sativa, fructu æstivo globoso è viridi purpurascence. Tourn. *Gros Oignonnet, i. e. the Great Onion Pear*. It is also called Amiré-roux, i. e. Brown Admired; and Roy d'Été, i. e. King of Summer; Archiduc d'Été; i. e. the Summer Archduke. This is a middle-sized round Pear, of a brownish colour next the sun; the flesh is melting, and the juice is passably good. This ripens the end of August.
20. PYRUS (*Averat*) sativa, fructu æstivo globoso sessili ex albido flavescence saccharato odorato. Tourn. *Robine*. It is also called Muscat d'Aoust, i. e. the August Muscat; Poire d'Averat, i. e. the Averat Pear; and Poire Royale, i. e. the Royal Pear. This is a roundish flat Pear, in shape very like a Bergamot; the stalk is long, strait, and a little spotted, and the eye is a little hollowed; the skin is smooth, and of a whitish yellow colour; the flesh is breaking, but not hard, and its juice is richly sugared and perfumed.

P Y R

fumed. It is a great bearer, and is esteemed one of the best summer Pears yet known; it ripens the end of August.

21. PYRUS (*Rose*) sativa, fructu æstivo globoso sessili odorato. Tourn. *Poire-rose*, i. e. the *Rose-Pear*; and *L'Epine-rose*, i. e. the *Thorny Rose*. This is a short round fruit, shaped like the great Onion Pear, but much larger; of a yellowish green colour, but a little inclining to red on the side next the sun; the stalk is very long and slender; the flesh is breaking, and the juice is musky: this ripens the end of August. The shoots and the leaves of this tree are large.
22. PYRUS (*Pouchet*) sativa, fructu æstivo globoso albedo saccharato. Tourn. *Poire du Pouchet*. This is a large, round, whitish Pear, shaped somewhat like the *Besideri*; the flesh is soft and tender, and the juice is sugary; this ripens the end of August.
23. PYRUS (*Parfumé*) sativa, fructu æstivo turbinato sessili saturatius rubente punctato. Tourn. *Poire de Parfumé*, i. e. the *perfumed Pear*. This is a middle-sized round fruit, whose skin is somewhat thick and tough, and of a deep red colour, spotted with brown; the flesh is melting, but dry, and has a perfumed flavour. This ripens the end of August.
24. PYRUS (*Boncrétien*) sativa, fructu æstivo oblongo magno, partim rubro, partim albedo odorato. Tourn. *Boncrétien d'Été*, i. e. the *Summer Boncrétien*, or *Good Christian*. This is a large oblong fruit, whose skin is smooth and thin; the side next the sun is of a beautiful red colour, but the other side is of a whitish green; the flesh is between breaking and tender, and is very full of juice, which is of a rich perfumed flavour. It ripens the beginning of September.
25. PYRUS (*Salviati*) sativa fructu æstivo globoso, ex rubro albedoque flavescence saccharato odorato. Tourn. *Salviati*. This Pear is pretty large, round, and flat, very much like the *Besideri* in shape, but not in colour; the stalk is very long and slender, and the fruit is a little hollowed both at the eye and stalk; the colour is red and yellow next the sun, but on the other side is whitish; the skin is rough, the flesh is tender, but a little soft, and has no core; the juice is sugary and perfumed, somewhat like the *Robine*, but is not near so moist. This ripens the beginning of September.
26. PYRUS (*Caillot-rosat*) sativa, fructu æstivo globoso sessili rufescence odorato. Tourn. *Caillot-rosat*, i. e. the *Rose-water Pear*. This is a large round Pear, somewhat like the *Messire Jean*, but rounder; the stalk is very short, and the fruit is hollowed like an Apple, where the stalk is produced; the skin is rough, and of a brown colour; the flesh is breaking, and the juice is very sweet. This ripens the middle of September.
27. PYRUS (*Choak-Pear*) sativa, fructu æstivo longo, acerbitate strangulationem minitante. Tourn. *Poire d'Etrangillon*, i. e. the *choaky Pear*. The flesh is red. This is seldom preserved in gardens, so there needs no description of it.
28. PYRUS (*Roufflet*) sativa, fructu æstivo oblongo è ferrugineo rubente, nonnunquam maculato. *Poire du Roufflet*, i. e. the *Roufflet Pear*. This is a large oblong Pear; the skin is brown, and of a dark red colour next the sun; the flesh is soft and tender, without much core; the juice is agreeably perfumed, if gathered before it be too ripe. This produces larger fruit on an espalier than on standard trees: it ripens the middle of September.
29. PYRUS (*Prince's Pear*) sativa, fructu æstivo subrotundo, partim rubro, partim flavescence, odorato. *Poire de Prince*, i. e. the *Prince's Pear*. This is a small roundish Pear, of a bright red colour next the sun, but a yellowish colour on the opposite side; the flesh is between breaking and melting; the juice is very high-flavoured: it is a great bearer. This ripens the middle of September, but will keep a fortnight good, which is what few summer-fruits will do.
30. PYRUS (*Mouille-bouche*) sativa, fructu æstivo globoso viridi, in ore liquefcente. *Gros Mouille-bouche*, i. e. the *great Mouthwater Pear*. This is a large round

P Y R

Pear with a smooth green skin; the stalk is short and thick; the flesh is melting, and full of juice, if gathered before it be too ripe, otherwise it is apt to grow meally. This ripens the middle of September.

31. PYRUS (*Bergamot d'Été*) sativa, fructu æstivo rotundo sessili saccharato, è viridi flavescence. *Bergamotte d'Été*, i. e. *Summer Bergamot*. This is by some called the *Hamden's Bergamot*. It is a pretty large, round, flat Pear, of a greenish yellow colour, and hollowed a little at both ends like an Apple; the flesh is melting, and the juice is highly perfumed. This ripens the middle of September.
32. PYRUS (*Bergamot Autumn*) sativa, fructu autumnali sessili saccharato odorato è viridi flavescence, in ore liquefcente. Tourn. *Bergamotte d'Automne*, i. e. the *Autumn Bergamot*. This is a smaller Pear than the former, but is nearly of the same shape; the skin is of a yellowish green, but changes to a faint red on the side next the sun; the flesh is melting, and its juice is richly perfumed. It is a great bearer, ripens the end of September, and is one of the best Pears of the season.
33. PYRUS (*Swiss Bergamot*) sativa, fructu autumnali turbinato viridi, striis sanguineis distincta. Tourn. *Bergamotte de Suisse*, i. e. the *Swiss Bergamot*. This Pear is somewhat rounder than either of the former; the skin is tough, and of a greenish colour, striped with red; the flesh is melting, and full of juice, but is not so richly perfumed as either of the former. This ripens the end of September.
34. PYRUS (*Beurré Rouge*) sativa, fructu autumnali suavisimo, in ore liquefcente. Tourn. *Beurré Rouge*, i. e. the *red Butter Pear*. It is called *l'Amboise*, and in Normandy *Isambert*; as also *Beurré gris*, i. e. the *gray Butter*; and *Beurré vert*, i. e. the *green Butter Pear*. All these different names of *Beurrés* have been occasioned by the difference of the colours of the same sort of Pear, which is either owing to the different exposure where they grew, or from the stock, those upon free stocks being commonly of a browner colour than those which are upon Quince stocks, whence some persons have supposed them to be different fruits, though in reality they are the same. This is a large long fruit, for the most part of a brown colour. The flesh is very melting, and full of a rich sugary juice. It ripens the beginning of October, and, when gathered from the tree, is one of the very best sort of Pears we have.
35. PYRUS (*Doyenne*) sativa, fructu autumnali turbinato sessili flavescence, & in ore liquefcente. Tourn. *Le Doyenne*, i. e. the *Dean's Pear*. It is also called by all the following names; *Saint Michel*, i. e. *Saint Michael*; *Beurré blanc d'Automne*, i. e. the *white Autumn Butter Pear*; *Poire de Neige*, i. e. the *Snow Pear*; *Bonne Ente*, i. e. a good Graft; the *Carlisle*, and *Valentia*. This is a large fruit, in shape somewhat like the *gray Beurré*, but is shorter and rounder; the skin is smooth, and, when ripe, changes to a yellowish colour; the flesh is melting, and full of juice, which is very cold, but it will not keep good much more than a week after it is gathered, being very subject to grow meally; it is a very indifferent fruit. This is a great bearer, and ripens the beginning of October.
36. PYRUS (*Verte-langue*) sativa, fructu autumnali longo viridique odorato, in ore liquefcente. Tourn. *La Verte-langue*, i. e. the *long green Pear*. It is also called *Mouille bouche d'Automne*, i. e. the *Autumn Mouthwater Pear*. This is a long fruit, which is very green when ripe; the flesh is melting, and very full of juice, which, if it grows upon a dry warm soil, and a free stock, is very sugary, otherwise it is but a very indifferent Pear. It ripens the middle of October, but some years they will keep till December.
37. PYRUS (*Messire Jean*) sativa, fructu autumnali tuberoso sessili saccharato, carne durâ. Tourn. *Messire Jean blanc & gris*, i. e. the *white and gray Monsieur John*. These, although made two sorts of fruit by many persons, are indubitably the same; the difference of their colour proceeding from the different soils

soils and situations where they grow, or the stocks on which they are grafted. This Pear, when grafted on a free stock, and planted on a middling soil, neither too wet nor over dry, is an excellent autumn Pear; but when it is grafted on a Quince stock, it is very apt to be stony; or if planted on a very dry soil, is very apt to be small and good for little; unless the trees are watered in dry seasons, which has rendered it less esteemed by some persons, who have not considered the cause of their hardness; for when it is rightly managed, there are not many Pears in the same season to be compared with it. This is a large roundish fruit, the skin is rough, and commonly of a brown colour; the flesh is breaking, and full of a rich sugared juice. It ripens the end of October, and will continue good near a month.

38. PYRUS (*Muscat fleur*) sativa, fructu autumnali globoso ferrugineo, carne tenerâ sapidissimâ. Tourn. *Muscat fleur*, i. e. the flowered Muscat. It is also called Muscat à longue queue d'Automne, i. e. the long-stalked Muscat of the Autumn. This is an excellent Pear, of a middling size, and round; the skin is of a dark red colour; the flesh is very tender, and of a delicate flavour. It ripens the end of October.
39. PYRUS (*Poire de Vigne*) sativa, fructu autumnali globoso ferrugineo, carne viscidâ. Tourn. *Poire de Vigne*, i. e. the Vine Pear. This is a round fruit, of a middling size; the skin of a dark red colour; the flesh is very melting, and full of a clammy juice; the stalk is very long and slender. The fruit should be gathered before it be full ripe, otherwise it grows mealy and soon rots. It ripens the end of October.
40. PYRUS (*Rouffeline*) sativa, fructu autumnali oblongo, dilute rufescente, saccharato, odoratissimo. Tourn. *Poire Rouffeline*, i. e. the Rouffeline Pear. It is also called in Touraine, Le Muscat à longue queue de la fin d'automne, i. e. the long-stalked Muscat of the end of autumn. This is by some English gardeners called the Brute-bonne, but that is a very different fruit from this. It is shaped somewhat like the Rouffellet, but the skin of this is smooth, and of a greenish yellow from the sun, but the side next the sun is of a deep red colour, with some spots of gray; the flesh is very tender and delicate; the juice is very sweet, with an agreeable perfume. It ripens the middle of October, but must not be long kept, lest it rot in the middle.
41. PYRUS (*Pendar*) sativa, fructu autumnali oblongo majori cinereo. Tourn. *Poire Pendar*, i. e. the Knave's Pear. This is very like the Cassiolette Pear, but is somewhat larger; the flesh is fine and tender; the juice is very much sugared. It ripens the end of October.
42. PYRUS (*Sucré vert*) sativa, fructu autumnali turbinato tuberoso viridi saccharato, in ore liquecente. Tourn. *Sucré vert*, i. e. The green Sugar Pear. This Pear is shaped like the Winter Thorn, but is smaller; the skin is very smooth and green; the flesh is very buttery; the juice is sugared, and of an agreeable flavour; but it is sometimes subject to be stony in the middle, especially if grafted on a Quince stock.
43. PYRUS (*Marquis*) sativa, fructu autumnali tuberoso sessili, è viridi flavescente, maculis nigris conferso, carne tenerâ saccharatâ. Tourn. *La Marquise*, i. e. the Marquis's Pear. This is often of two different shapes, according to the nature of the soil where they are planted; for when the soil is dry, the fruit very much resembles a fine Blanquet; but when the soil is very rich and moist, it grows much larger. It is a well-shaped Pear, flat at the top; the eye is small and hollowed; the skin is of a greenish yellow, a little inclining to red on the side next the sun. If this Pear does not change yellow in ripening, it is seldom good; but if it does, the flesh will be tender and delicate, very full of juice, which is sugared. It ripens the beginning of November.
44. PYRUS (*Chat-brûlé*) sativa, fructu autumnali oblongo, partim albido, partim rufescente. *The Chat-brûlé*, i. e. the Burnt Cat. It is also called Pucelle de Xaintogne, i. e. the Virgin of Xaintogne. This is a

small oblong Pear, shaped much like the Martin Set; but differs from it in colour, this being of a pale colour on one side, but of a dark brown on the other; the skin is smooth; the flesh is tender, but dry, and, if kept a short time, is apt to grow mealy. It is in eating the beginning of November.

45. PYRUS (*Besidéri*) sativa, fructu autumnali globoso sessili, ex albido flavescente. *De Besidéri*. It is so called from Heri, which is a forest in Bretagne, between Rennes and Nantes; where this Pear was found. This is a middle-sized round Pear, of a pale green, inclining to a yellowish colour; the stalk is very long and slender; the flesh is dry, and but very indifferent for eating, but it bakes well. It ripens the middle of November.
46. PYRUS (*Crasane*) sativa, fructu brumali sessili, è viridi flavescente, maculato, utrinque umbilicato, in ore liquecente. Tourn. *The Crasane, or Bergamot Crasane*. It is also called Beniré Plat, i. e. the flat Butter Pear. This is a middle-sized Pear, hollowed at the crown like an Apple; the stalk is very long and crooked; the skin is rough, of a greenish yellow colour when ripe, covered over with a russet coat; the flesh is extremely tender and buttery, and is full of a rich sugared juice, and is the very best Pear of the season. This is in eating the middle of November.
47. PYRUS (*Dauphine*) sativa, fructu brumali turbinato sessili flavescente saccharato odorato, in ore liquecente. Tourn. *Lansac ou la Dauphine*, i. e. the Lansac or Dauphine Pear. This Pear is commonly about the size of a Bergamot, of a roundish figure, flat towards the head, but a little produced towards the stalk; the skin is smooth, and of a yellowish green colour; the flesh is yellow, tender, and melting; the juice is sugared, and a little perfumed; the eye is very large, as is also the flower, and the stalk is long and fruit. When this Pear is upon a free stock, and planted on a good soil, it is one of the best fruits of the season; but when it is on a Quince stock, or upon a very dry soil, the fruit will be small, stony, and worth little. It ripens the end of November.
48. PYRUS (*Martin-Sec*) sativa, fructu brumali oblongo, partim intense, partim dilute ferrugineo, saccharato, odorato. Tourn. *Martin-Sec*, i. e. the Dry Martin. This is sometimes called the Dry Martin of Champagne, to distinguish it from another Dry Martin of Burgundy. This Pear is almost like the Rouffellet in shape and colour, which has occasioned some persons to give it the name of Winter Rouffellet. It is an oblong Pear, whose skin is of a deep russet colour on one side, but the other side is inclining to a red; the flesh is breaking and fine; the juice is sugared, with a little perfume, and if grafted on a free stock, is an excellent Pear; but if it be on a Quince stock, it is very apt to be stony. It is in eating the end of November, but if they were permitted to hang their full time on the tree, will keep good two months.
49. PYRUS (*Bigarrade*) sativa, fructu brumali magno sessili, è cinereo flavescente. Tourn. *La Villaine de Anjou*, i. e. the Villain of Anjou. It is also called Poire Tulipée, i. e. the Tulip Pear, and Bigarrade, i. e. the Great Orange. This is a large round Pear, with a very long slender stalk; the skin is of a pale yellow colour; the flesh is breaking, but not very full of juice. This is in eating the end of November.
50. PYRUS (*Poire de gros queue*) sativa, fructu brumali flavescente odoratissimo, pediculo crassiori. Tourn. *Poire de gros queue*, i. e. the large stalked Pear. This is a large roundish Pear, with a yellow skin; the stalk is very thick, from whence it had the name; the flesh is breaking and dry, and has a very musky flavour; but it is apt to be stony, especially if it be planted in a dry soil, or grafted on a Quince stock, as are most of the perfumed Pears.
51. PYRUS (*Amadote*) sativa, fructu brumali turbinato rufescente odorato. *L'Amadote*, i. e. The Amadote Pear. This is a middle-sized Pear, somewhat long, but flat at the top, the skin is generally rough, and of a russet colour; the flesh is dry and high flavoured, if grafted on a free stock. The wood of this tree is generally

generally thorny, and is esteemed the best sort of Pear for stocks to graft the melting Pears upon, because it gives them some of its fine musky flavour. It is in eating the beginning of December, but will keep good six weeks.

52. PYRUS (*Bouvar*) sativa, fructu brumali, globoso, dilute virente, tuberoso, punctato, in ore liquefcente. Tourn. *Petit Oin*, i. e. *Little Lard Pear*. It is also called Bouvar and Roussette d'Anjou, i. e. the Russet of Anjou; and Amadont, and Marveille d'Hyver, i. e. the Wonder of the Winter. This Pear is of the size and shape of the Ambret or Leschasserie, but the skin is of a clear green colour, and a little spotted; the stalk is pretty long and slender; the eye is large, and deeply hollowed; the flesh is extremely fine, and melting; the juice is much sugared, and has an agreeable musky flavour. It is in eating the middle of December, and is esteemed one of the best fruits in that season. This is better on a free stock than upon the Quince.

53. PYRUS (*Louisebonne*) sativa, fructu brumali, longo, è viridi albicante, in ore liquefcente. Tourn. *Louisebonne*, i. e. *the Good Lewis Pear*. This Pear is shaped somewhat like the St. Germain, or the Autumn Verte-longue, but is not quite so much pointed; the stalk is very short, fleshy, and somewhat bent; the eye and the flower are small; the skin is very smooth; the colour is green, inclining to a pale colour when ripe; the flesh is extremely tender and full of juice, which is very sweet, especially when it grows upon a dry soil, otherwise it is apt to be very large and ill tasted. It is in eating the beginning of December.

54. PYRUS (*Colmar*) sativa, fructu brumali, tuberoso, è viridi flavescente, punctato, saccharato. Tourn. *Poire de Colmar*, i. e. *the Colmar Pear*. It is also called Poire Manne, the Manna Pear, and Bergamotte tardive, the late Bergamot. This Pear is somewhat like a Boncrétien in shape, but the head is flat; the eye is large, and deeply hollowed; the middle is larger than the head, and is sloped toward the stalk, which is short, large, and a little bent; the skin is green, with a few yellowish spots, but is sometimes a little coloured on the side next the sun; the flesh is very tender, and the juice is greatly sugared. It is in eating the latter end of December, but will often keep good till the end of January, and is esteemed one of the best fruits of that season.

55. PYRUS (*L'Eschasserie*) sativa, fructu brumali, globoso, citriformi, flavescente, punctato, in ore liquefcente, saccharato, odoratissimo. Tourn. *L'Eschasserie*. It is also called Vertelongue d'Hyver, i. e. the Winter long green Pear, and Besidéri Landri, i. e. the Landry Wilding. This Pear is shaped like a Citron; the skin is smooth, and of a green colour, with some spots while it hangs on the tree, but as it ripens it becomes of a yellowish colour; the stalk is strait and long; the eye is small, and not hollowed; the flesh is melting, and buttery; the juice is sugared, with a little perfume. It is in eating the latter end of December.

56. PYRUS (*Virgoulense*) sativa, fructu brumali longo, è viridi flavescente, in ore liquefcente, saccharato. Tourn. *Le Virgoulé*, or *La Virgoulense*. It is also called Bujaleuf, and Chambrette; and Poire de Glasse, i. e. the Ice Pear in Gascoigne; but it is called Virgoule, from a village of that name in the neighbourhood of St. Leonard in Limousin, where it was raised and sent to Paris by the Marquis of Chambrét. This Pear is large, long, and of a green colour, inclining to yellow as it ripens; the stalk is short, fleshy, and a little bent; the eye is of a middling size, and a little hollowed; the skin is very smooth, and sometimes a little coloured towards the sun; the flesh is melting, and full of a rich juice. It is in eating the latter end of December, and will continue good till the end of January, and is esteemed one of the best fruits of the season; but the tree is very apt to produce vigorous shoots, and the blossoms being generally produced at the extreme part of the shoot, when

they are shortened, the fruit will be entirely cut away, which is the reason it is condemned as a bad bearer; but when it is grafted on a free stock, it ought to be allowed at least forty feet to spread; and if upon a Quince stock, it should be allowed upwards of thirty feet, and the branches trained in against the espalier or wall, at full length, in a horizontal position, as they are produced. Where this tree is thus treated, it will bear very plentifully, and the fruit will be good.

57. PYRUS (*Ambrette*) sativa spinosa, fructu globoso, fessili, ferrugineo, in ore liquefcente, saccharato, odoratissimo. Tourn. *Poire d'Ambrette*. This is so called from its musky flavour, which resembles the smell of the Sweet Sultan Flower, which is called Ambrette in France. This Pear is like the Leschasserie in shape, but is of a russet colour; the eye is larger, and more hollowed; the flesh is melting, and the juice is richly sugared and perfumed; the seeds are large and black, and the cells in which they are lodged are very large; the wood is very thorny, especially when grafted on free stocks. The fruit is in eating the latter end of December, and continues good till the latter end of January, and is esteemed a very good fruit by most people.

58. PYRUS (*Epine d'Hyver*) sativa, fructu brumali, magno, pyramidato, albido, in ore liquefcente, saccharato, odorato. Tourn. *Epine d'Hyver*, i. e. *Winter-thorn Pear*. This is a large fine Pear, nearly of a pyramidal figure; the skin is smooth, and of a pale green colour, inclining to yellow as it ripens; the stalk is short and slender; the flesh is melting and buttery; the juice is very sweet, and in a dry season, is highly perfumed; but when it is planted on a moist soil, or the season proves wet, it is very insipid, so that it should never be planted on a strong soil. It ripens the end of December, and will continue good two months.

59. PYRUS (*Saint Germain*) sativa, fructu brumali longo, è viridi flavescente, in ore liquefcente. Tourn. *La Saint Germain*, i. e. *the St. Germain Pear*. It is also called L'Inconnue de la Fare, i. e. the Unknown of La Fare; it being first discovered upon the banks of a river which is called by that name, in the parish of St. Germain. This is a large long Pear, of a yellowish green colour when ripe; the flesh is melting, and very full of juice, which in a dry season, or if planted on a warm dry soil, is very sweet; but when it is planted on a moist soil, the juice is very apt to be harsh and austere, which renders it less esteemed by some persons, though in general it is greatly valued. This is in eating from the end of December till February.

60. PYRUS (*Saint Austin*) sativa, fructu brumali tuberoso subacido flavescente punctato. Tourn. *Saint Austin*. This is about the size of a middling Virgoulé Pear, but is somewhat shorter and slenderer near the stalk; the skin is of a fine Citron colour, spotted with red on the side next the sun; the flesh is tender, but not buttery, and is pretty full of juice, which is often a little sharp, which to some persons is disagreeable, but others value it on that account. This is in eating in December, and will continue good two months.

61. PYRUS (*Boncrétien d'Espagne*) sativa, fructu brumali pyramidato, partim purpureo, punctis nigris conferto, flavescente. Tourn. *Boncrétien d'Espagne*, i. e. *the Spanish Boncrétien*. This is a large Pear, of a pyramidal form, of a fine red or purple colour on the side next the sun, and full of small black spots; the other side is of a pale yellow colour, the flesh is breaking, and when it is on a light rich soil, and grafted on a free stock, its juice is very sweet. It ripens in the end of December, and will continue good a month or six weeks. If this be grafted on a Quince stock, it is very apt to be dry and stony. This is a very good fruit for baking.

62. PYRUS (*Poire de J'iere*) sativa, fructu brumali, magno, oblongo, tubinato, ferrugineo, utrinque umbilicato. Tourn. *Poire de J'iere*, i. e. *the Pearl Pear*.

It is also called Gros Ratteau Gris, i. e. the gray raked Pear; and Poire d'Amour, i. e. the lovely Pear. In England this is called Parkinson's Warden, or the Black Pear of Worcester. This is a very large Pear, each of which commonly weighs a pound or more; the skin is rough, and of an obscure red colour on the side next the sun, but somewhat paler on the other side; the stalk is very short, and the eye is greatly hollowed. This is not fit for eating, but bakes or stewes exceedingly well, and is in season from December to March.

63. PYRUS (*Befi de Caffoy*) fativa, fructu brumali parvo flavescente, maculis rubris consperso. Tourn. *Befi de Caffoy*, i. e. *the Wilding of Caffoy*; a forest in Bretagne, where it was discovered, and passes under the name of Roufflet d'Anjou. It is also called Petit Beurre d'Hyver, i. e. Small Winter Butter Pear. This is a small oblong Pear, of a yellowish colour, spotted with red; the flesh is melting, and the juice is very rich. It is in eating in December and January. This is a prodigious bearer, and commonly produces its fruit in large clusters, provided it be not too much pruned; for it generally produces its blossom-buds at the extremity of its shoots, which if shortened, the fruit would be cut away. There was a tree of this kind in the gardens of Camden-house near Kensington, which generally produced a great quantity of fruit.

64. PYRUS (*Martin-fire*) fativa, fructu brumali turbato inæquali, ventre tumido, partim purpureo, partim flavescente. Tourn. *Rouville*. It is also called Hocrenaille and Martin-fire, i. e. the Lord Martin Pear. This Pear is about the size and shape of a large Roufflet; the eye is of a middling size, and hollowed a little; the middle of the Pear is generally swelled more on one side than on the other, but is equally extended towards the stalk; the skin is very smooth and soft, and is of a lively red colour next the sun, but on the other side it changes yellow as it ripens. The flesh is breaking and full of juice, which is very sweet and a little perfumed; but if grafted on a Quince stock, is very apt to be small and stony.

65. PYRUS (*Citron d'Hyver*) fativa, fructu brumali citriformi flavescente duro molchato odoratissimo. Tourn. *Citron d'Hyver*, i. e. *the Winter Citron Pear*. It is also called the Musk Orange Pear, in some places. This is a pretty large Pear, in shape and colour very like an Orange or Citron, from whence it had its name. The flesh is hard and dry, and very subject to be stony, for which reasons it is not valued as an eating Pear, but will bake very well. It is in season from December to March.

66. PYRUS (*Roufflet d'Hyver*) fativa, fructu brumali oblongo, è viridi flavescente, saccharato, saporis austeri. Tourn. *Roufflet d'Hyver*, i. e. *the Winter Roufflet*. This is by some supposed to be the same Pear as is called the Dry Martin, but it is very different from that in several particulars. The colour of this is a greenish yellow, inclining to brown; the stalk is long and slender, and the flesh is buttery and melting, and generally full of juice, which is very sweet, but the skin is apt to contain an austere juice, so that if it be not pared, it is apt to be disagreeable to many persons' palates. It is in eating in January and February.

67. PYRUS (*Portail*) fativa Pictaviensis, fructu brumali globoso sessili saccharato odorato. Tourn. *Poir Portail*, i. e. *the Gate Pear*. This Pear was discovered in the province of Poitou, where it was so much esteemed, that they preferred it to most other fruit, though in the opinion of the most curious judges, it does not deserve the great character which is given to it; for it rarely happens that it proves good for eating, being generally dry, stony, and hard, unless in extraordinary seasons, and upon a very good soil. This must always be grafted on a free stock, and should be planted on a light rich soil; and in very dry seasons the trees should be watered, otherwise the fruit will be stony. It is in season from January to March, and bakes well.

68. PYRUS (*Franc-real*) fativa, fructu brumali magno globoso flavescente, punctis rubris consperso. Tourn. *Franc-real*. It is also called Fin-or d'Hyver, i. e. the Golden End of Winter. This is a very large Pear, almost of a globular figure; the skin is yellow, spotted with red; the stalk is short, and the wood of the tree mealy. The flesh of this Pear is dry, and very apt to be stony, but it bakes exceeding well, and continues good from January till March.

69. PYRUS (*Easter Bergamot*) fativa, fructu brumali turbato sessili subacido flavescente, punctis asperioribus consperso. Tourn. *Bergamotte Bugi*. It is also called Bergamotte de Pasque, i. e. the Easter Bergamot. It is a large Pear, almost round, but is a little produced in length towards the stalk; the eye is flat and the skin is green, having many rough protuberances like spots dispersed all over, but, as it ripens, becomes yellowish; the flesh is breaking, and in a good season the juice is sweet; but it must have a free stock, a south-east wall, and have a good soil, otherwise it is apt to be stony and austere. It is in eating from February till April.

70. LE (*Muscat of Germany*) MUSCAT D'ALAMAN, i. e. *The German Muscat*. This is an excellent Pear, more long than round, of the shape of the Winter-royal, but is less toward the eye, and is more ruffet, and of a red colour next the sun; it is buttery, melting, and a little musky. This is in eating in March, April, and sometimes in May, if it is well preserved.

71. LE BERGAMOTTE (*Holland Bergamot*) D'HOLLANDE, i. e. *The Holland Bergamot*. It is large and round, of the shape of the ordinary Bergamot. The colour is greenish, the flesh is half buttery and tender, the juice is highly flavoured. This is a very good Pear, and will keep till April.

72. LE POIRE (*Naples Pear*) DE NAPLES, i. e. *The Pear of Naples*. This is a pretty large, long, greenish Pear; the flesh is half breaking; the juice is sweet, and a little vinous. It is in eating in March. I am in doubt whether this Pear is not in some places taken for a Saint Germain, for there is a Pear in some gardens, very like the Saint Germain, which will keep till April, and this Pear agrees with the characters of that. It is called in England the Easter St. Germain.

73. PYRUS (*Boncrétien d'Hyver*) fativa, fructu brumali magno pyramidato, è flavo nomihil rubente. Tourn. *Boncrétien d'Hyver*, i. e. *the Winter Boncrétien Pear*. This Pear is very large and long, of a pyramidal figure; the skin is of a yellowish colour, but the side next the sun inclines to a soft red; the flesh is tender and breaking, and is very full of rich sugared juice. This is esteemed in France one of the best winter Pears, but in England it is seldom so good; though I am fully satisfied, if it were grafted on a free stock, and planted in a good soil, against a wall exposed to the south-east, and the branches trained at full length, it might be rendered more acceptable than it is at present in England.

74. PYRUS (*Cadillac*) fativa, fructu brumali magno, cydoniæ facie, partim flavo, partim purpureo. Tourn. *Catillac, or Cadillac*. This is a large Pear, shaped somewhat like a Quince; the skin is for the most part of a yellow colour, but changes to a deep red on the side next the sun; the flesh is hard, and the juice austere, but it is a very good fruit for baking, and being a plentiful bearer, deserves a place in every good collection of fruit. It will be good from Christmas to April, or longer.

75. PYRUS (*Pafforelle*) fativa, fructu brumali oblongo flavescente, punctis rubris consperso. *La Pafforelle*. This Pear is of the size and shape of a fine Roufflet; the stalk is short and crooked; the skin is somewhat rough, of a yellowish colour, spotted with red; the flesh is tender and buttery, and when it grows on a dry soil, the juice is very sweet; but on a wet soil, or in moist years, it is subject to have an austere taste. This Pear is in eating in February and March.

76. PYRUS (*Double Flew*) fativa, fructu brumali sessili, partim flavescente, partim purpurascete. Tourn.

La Double Fleur, i. e. the double-flowering Pear. This is so called, because the flowers have a double range of petals or leaves. It is a large short Pear; the stalk is long and strait; the skin is very smooth, and of a yellowish colour, but the side next the sun is commonly of a fine red or purple colour. This is by some esteemed for eating, but it is generally too austere in this country for that purpose. It is the best Pear in the world for baking or composts. It is good from February to May.

77. PYRUS (*Saint Martial*) sativa, fructu brumali oblongo, partim flavescente, partim purpurascete. *Saint Martial*. It is also called in some places *Poire Angelique*, i. e. the Angelic Pear; and in the south of France, *Poire Douce*. This Pear is oblong, in shape like the Boncrétien, but not so large, and a little flatter at the crown; it has a very long stalk; the skin is smooth and yellowish, but on the side next the sun it turns to a purplish colour; the flesh is tender and buttery, and the juice is very sweet. This is in eating in February and March.

78. PYRUS (*Best Chaumontelle*) sativa, fructu brumali oblongo, partim albedo, partim purpureo odorato, saccharato. *La Poire de Chaumontelle*, or *Best de Chaumontelle*, i. e. the Wilding of Chaumontelle. This Pear is in shape somewhat like the Autumn Beurré, but is flatter at the crown; the skin is a little rough, of a pale green colour, but turns to a purplish colour next the sun; the flesh is melting; the juice is very rich, and a little perfumed. It is in eating from November to January, and is esteemed by some as the best late Pear yet known.

79. PYRUS (*Carmelite*) sativa, fructu brumali globoso sessili cinereo maculis amplis obscurioribus consperso. *Tourn. Carmelite*. This is a middle-sized Pear, of a roundish form; the skin is of a gray colour on one side, but is inclining to a red on the other, having some broad spots of a dark colour all over; the flesh is commonly hard and dry, so that it is not very much esteemed. It is in season in March.

80. PYRUS (*Union*) sativa, fructu brumali maximo pyramidato, dilute virente. *The Union Pear*, otherwise called *Dr. Uvedale's St. Germain*. This is a very large long Pear, of a deep green colour, but the side next the sun doth sometimes change to a red as it ripens. This is not fit for eating, but bakes very well; and being a great bearer, and a very large fruit, deserves a place in every good collection. It is in season from Christmas to April.

There are many other sorts of Pears, which are still continued in some old gardens; but as those here mentioned are the best sorts known at present, it would be needless to enumerate a great quantity of ordinary fruit; since every one who intends to plant fruit-trees, would rather chuse those which are the most valued, the expence and trouble being the same for a bad sort of fruit as a good one. Indeed I have inserted many more than are really worth planting, in order to please such who are fond of great variety; but whoever hath a mind to make choice of such only as are good, may easily distinguish them, by attending to the account given of each sort, and hereby every person is at liberty to please himself; for it is not every one who prefers a Beurré Pear, though that is generally esteemed the very best in its proper season; there are some who admire the Messire Jean, for the firmness of its flesh, which to others is a great objection against it; so that as some esteem the breaking, and others the melting Pears, I have distinguished them by their descriptions in such a manner, that every one may make choice of the kinds of fruit which are agreeable to their palates; and the different seasons in which each kind is in eating, being exhibited (allowing a little for the difference of seasons, which are earlier some years than others) it is not very difficult for a person to make a collection of good Pears to succeed each other throughout the season of these fruits, both for eating and baking.

The time of each fruit ripening, as here set down, is taken at a medium for seven years, and in the neigh-

bourhood of London, where all sorts of fruit generally ripen a fortnight or three weeks earlier than in almost any part of England; and it is very obvious to every person who will attend to the culture of fruit-trees, that their time of ripening is accelerated by long cultivation; for many of the sorts of Pears, which some years past rarely became ripe in England, unless they grew against the best aspectted walls, are now found to ripen extremely well on espaliers and dwarfs; and those Pears which seldom were in eating till January, are ripe two months earlier. There is also a very great difference in their time of ripening in different seasons, for I have known the fruit of a Pear-tree in one year all ripe and gone by the middle of October, and the very next year the fruit of the same tree has not been fit to eat till the end of December, so that allowance should be made for these accidents. The Best de Chaumontelle Pear, about forty years past, was seldom fit to eat before February, and has continued good till the middle of April, but now this Pear is commonly ripe in November; and when it is planted on a warm soil, and against a good aspectted wall, it is in eating the middle or end of October. This forwarding of the several kinds of Pears, may be in some measure owing to the stocks upon which they are grafted; for if they are grafted upon early summer Pear stocks, they will ripen much earlier than when they are upon hard winter Pear stocks; and if some of the very soft melting Pears were grafted upon such stocks as are raised from the most austere fruit, such as are never fit to eat, and of which the best perry is made, it would improve those fruits, and continue them much longer good; or if the common free stocks were first grafted with any of these hard winter Pears, and when they have grown a year, then to graft or bud these soft melting Pears upon them, it would have the same effect; but the Pears so raised will require a year's more growth in the nursery, and consequently cannot be sold at the same price as those which are raised in the common method, these requiring to be twice budded or grafted, so that there is double labour, beside standing a full year longer; but this difference in the first expence of the trees, is not worth regarding by any person who is desirous to have good fruit; for the setting out in a right way is that which every one should be the most careful of, since by mistaking at first, much time is lost, and an after expence of new trees often attends it.

Another cause of fruits ripening earlier now than they formerly did, may be from the length of time they have been cultivated; for it is very certain, that most sorts of plants have been greatly forwarded and improved by culture, within the space of thirty or forty years, as may be known from the several sorts of excellent plants, which are cultivated in the kitchen-gardens, and of which sorts there are many which are annually improving; and if we look back to the best French authors who have written on the subject of fruit-trees, we shall find, that the times of ripening of many sorts of Pears are put down a month or six weeks later about fifty or sixty years ago, than they are now found to ripen about Paris; and here about London it is much the same, for I cannot find they are the least forwarder in the times of their ripening at Paris than at London.

The ripening of these fruits may also be accelerated by the method of pruning and managing these trees, which are greatly improved within the space of a few years past; for if we look into the directions which are given by the best writers on this subject, we shall soon discover how little they knew fifty years ago, of the true method of pruning and managing most sorts of fruit-trees, scarce one of them making any difference in the management of the different kinds of fruit. Pears are propagated by budding or grafting them upon stocks of their own kind, which are commonly called free stocks, or upon Quince stocks, or Whithorn, upon all which these fruits will take; but the latter sort of stock is now seldom used, because they

never

never keep pace in their growth with the fruit budded or grafted upon them; as also because the fruit upon such stocks are commonly drier, and more apt to be stony, than when they are upon Pear stocks. Quince stocks are greatly used in the nurseries for all sorts of Pears which are designed for dwarfs or walls, in order to check the luxuriancy of their growth, so that they may be kept within compass better than upon free stocks. But against the general use of these stocks, for all sorts of Pears indifferently, there are very great objections: 1st, Because some sorts of Pears will not thrive upon these stocks, but in two or three years decay, or at most will but just keep alive. 2dly, Most of the sorts of hard breaking Pears are rendered stony, and good for little; so that whenever any of these sorts are thus injudiciously raised, the fruit, although the kind be ever so good, is condemned as good for nothing by such as are not well acquainted with it, when the fault is entirely owing to the stock on which it was grafted. On the contrary, most melting buttery Pears are greatly improved by being upon Quince stocks, provided they are planted on a strong soil; but, if the ground be very dry and gravelly, no sort of Pear will do well upon Quince stocks in such places.

These general directions being given, there is no occasion to repeat any part of the method in which these stocks are raised, and the fruits budded or grafted thereon, which has been already mentioned under the article of NURSERIES.

The distance which these trees should be planted either against walls or espaliers, must not be less than forty feet; for if they have not room to spread on each side, it will be impossible to preserve them in good order, especially those on free stocks, for the more these trees are pruned, the more they will shoot; and, as I said before, many sorts of Pears produce their blossom-buds first at the extremity of the former year's shoots, so that when they are shortened, the fruit will be cut away, and this cannot be avoided, where the trees have not room allowed in their first planting.

This distance, I doubt not, will be objected to by many who have not fully attended to the growth of these trees, especially as it hath been the general practice of most gardeners to plant these trees at less than half the distance which is here mentioned; but, whoever will be at the trouble to view any of these trees which have been some years standing, they will always find, if by accident, one of these trees has been planted against a building, where the branches have had room to spread, that this tree has produced more fruit than twelve trees which have been crowded close, and have not room for their branches to extend. There are some Pear-trees now growing, which spread more than fifty feet in length, and are upward of twenty feet high, which produce a much greater quantity of fruit than if there had been three trees in the same room they would have done, as there are examples enough to prove, where trees are planted against houses and the ends of buildings at about twelve feet, or much less distance, because there is height of walling for them to grow, which is the reason commonly given by those who plant these trees so close together. But one tree will bear more fruit, when the branches are trained horizontally, than three or four trees, whose branches are led upright, and there never can be any danger of the upper part of the wall being left naked or unfurnished; for I have seen a Pear-tree which has spread more than fifty feet in width, and covered the wall upward of thirty-six feet in height; this was a summer Boncrétien Pear, and was extremely fruitful, which rarely happens to this sort when they are not allowed a large share of room. The finest tree of this sort of Pear, which I have ever seen, was a large standard-tree in my own possession, whose stem was not more than ten feet high, where the branches came out regularly on every side, and extended near thirty feet from the trunk, many of which were by the weight of the fruit in summer

brought down to the ground, so they were obliged to be supported with poles all around the tree toward the extremity of the branches, to prevent their lying upon the ground; and this tree had its branches so disposed as to form a natural parabola of forty feet in height, bearing from the lowest to the highest branches; so that in a kindly season, when the blossoms escaped the frost, it hath produced upward of two thousand Pears, which were much better flavoured than any of the same sort which I have yet tasted. This instance I mention, only to shew how much one of these trees will spread, if proper room be allowed it; and also to observe, that as the branches of this tree had never been shortened, they were fruitful to their extremities. This shews the absurdity of the French gardeners, who do not allow more than ten or twelve feet distance to these trees; and some of their most improved writers on this subject have advised the planting an Apple-tree between the Pear-trees, where they are allowed twelve feet; and yet these authors afterward say, that a good Pear-tree will shoot three feet each way in one year; therefore, according to their own observation, the trees so planted will have their branches meet together in two or three years at most, and what must be the case with such trees in five or six years is not difficult to know. But this method of planting has not been peculiar to the French, for most of the gardens in England have been little better planted. Indeed, those persons who were intrusted with the making and planting most of the English gardens, had little skill of their own, so were obliged to follow the directions of the French gardeners; of whom they had so great an opinion, as to get their books translated, and to these have added some trifling notes, which rather betray their weakness; for, where they have objected to the little room which their authors had allowed to these trees, they have, at the most, allowed them but three feet more; from which it is plain, they had not considered the natural growth of the trees, and whoever departs from nature, may be justly pronounced an unskilful gardener.

As most of the English gardens have been made and planted by persons of little judgment, it is very rare to find any of them which produce much fruit; for although many of these gardens have been totally altered and new planted, yet they have seldom been much altered for the better; and the possessors have been put to the expence of removing the old trees, also the earth of their borders, and to purchase new trees, which have been planted perhaps a foot or two farther asunder, than the old trees which were removed; so that when the young trees have grown a few years, they were in the same condition as the old, and it will be the loss of so many years to the owner: but this will constantly be the case, when it is the interest of the persons employed, who can sell so many young trees; and the planting of three times the number of trees in a garden, more than is proper, may in some measure be ascribed to the same, though in many instances I shall be inclinable to think they have proceeded from ignorance, rather than design. But where fruit-trees have been thus injudiciously planted, if the stocks are healthy and good, the best way to recover this loss is to dig up two or three, and leave every third or fourth tree, according to the distance which they were planted, and spread down the branches of those which are left horizontally; I mean, all such as are capable of being so brought down: but those which are too stubborn for this, should be cut off near the stem, where there will be new shoots enough produced to furnish the wall or espalier; and if the sort of fruit is not the same as desired, the young branches may be budded the same summer, or grafted the following spring with any other sort of Pear, and hereby many years may be saved; for one of these old trees so budded or grafted, will spread to a much greater length, and produce more fruit, when thus managed, in three years, than a new tree will in ten or twelve, especially if the ground

ground is mended. This is a method which I have practised with great success, where I have been employed to mend the blunders of these great gardeners, as they are stiled, and hereby the walls and espaliers have been well furnished in a few years.

But the next thing to be done, after being furnished with proper trees, is the preparing the ground to receive them; in the doing of which, there should be great regard had to the nature of the soil, where the trees are to grow; for, if it is a strong stiff land, and subject to wet in the winter, the borders should be raised as much above the level of the ground as you conveniently can. And if under the good soil there is a sufficient quantity of lime, rubbish, or stones laid to prevent the roots of the trees from running downward, it will be of great service to the trees. The borders for these should not be less than eight feet broad, but, if they are twelve, it will be still better. And as these borders may be planted with such sorts of esculent plants as do not grow large, or whose roots do not grow deep, or mat together on the surface, these will do no harm to the Pear-trees; for these are not so nice in their culture as Peach and Nectarine-trees, so the turning the ground, and mending it for these crops, will rather improve than injure the trees, provided the plants do not shade the trees, or are not suffered to stand too long upon the borders. But all the Cabbage kind, as also Beans, should be excluded from these borders, because they root deep in the ground, and draw much nourishment from the trees.

But if the soil is shallow, and the bottom is either gravel or chalk, there must be a sufficient depth of good earth laid upon the borders, so as to make them two feet and a half deep; for if the ground is not of this depth, the trees will not thrive well. And, in doing of this, I must caution every person not to dig out the gravel or chalk in a trench, (as is by some practised) and fill this trench with good earth; for by so doing, when the roots of the trees are extended to the width of the trench, they will meet with the gravel which will stop them, so that they will be confined, as if they were in tubs of earth, whereby the trees will soon shew their distress; therefore, when the gravel or chalk is removed, it should be entirely taken away over the whole border, otherwise it will be better to raise the whole border above it.

If the garden is to be new-made from a field, then all the good earth on the surface should be carefully preserved; and, if the good ground is taken out where the walks are designed to be made, and laid upon the borders, or in the quarters, it will add to the depth of the soil, and save expence in bringing in of new earth. If the ground can be prepared one year before it is planted, the trees will thrive the better; for by laying the ground in ridges, and turning it over two or three times, it will loosen the soil, and render it much better for planting; but in trenching or ploughing of the ground, there should be great care taken not to go deeper than the ground is good, otherwise all the good soil will be buried below the roots, and the bad ground will be turned on the top, which is what I have known done at a great expence by persons, who have been at the top of their profession, and have thereby entirely ruined the gardens.

Where there is a necessity of bringing any fresh earth for the borders, it will be proper to do it as soon as possible, and to mix this with the surface of the earth of the borders, that it may be turned over two or three times, that the parts may be well mixed and incorporated before the trees are planted; and, if some very rotten dung is added to this, it will greatly improve it. In choosing of the earth which is to be brought into the garden, there should be this care, viz. That if the natural soil of the garden is light and dry, then the new earth should be loamy and stiff; but where the natural soil is strong or loamy, then the new earth should be light and sandy, which will loosen the parts of the natural soil, and greatly mend it.

There are some persons who recommend laying the

whole depth of the borders with what they call virgin earth, that is, such as is taken from a pasture where the land has not been ploughed; but if this is not brought into the garden at least one year before the trees are planted, that by turning it over often it may be sweetened, it will not be so good as that which is taken from a kitchen-garden, where the land is good, and has been well wrought; for by often turning and breaking the soil, it will be better prepared to receive the trees.

Others recommend mixing a great quantity of rotten dung with the earth of the borders, but this is not so proper; for, by making the ground too rich, it will only encourage the luxuriant growth of the trees; therefore it is always better to mend the borders from time to time as they may require, and not to add so much dung in the first making them.

Another care is required in making the borders on wet ground, which is to contrive some covered drains to convey off the water in winter, otherwise, by this being detained about the roots of the trees, it will greatly prejudice them; and in building the walls round a kitchen-garden, where the ground is inclinable to be wet, there should be some arches turned in the foundations of those walls which are in the lowest part of the garden, to let off the wet.

The manner of preparing these trees for planting is the same as hath been directed for other fruit-trees, viz. to cut off all the small fibres from the roots, and to shorten some of the longest roots, and cut off all the bruised ones, or such as shoot downright; this being done, you should plant them in the places intended at the before-mentioned distance. The best time to plant these trees (if upon a middling or dry soil) is in October or November, leaving their heads on till spring, which should be fastened either to the walls or stakes, to prevent the wind from disturbing their roots; and in the beginning of March their heads should be cut off in the manner already directed for Peaches and other fruit-trees, observing also to lay some mulch upon the surface of the ground about their roots when they are planted, as hath been several times already directed for other trees; but in wet ground the trees may be planted in February, or the beginning of March, at any time before the buds are much swelled, but these may be cut down when they are planted.

The first summer after planting, the branches should be trained to a wall or espalier (against which they are planted) in a horizontal position, as they are produced, without shortening them; and the Michaelmas following, some of these shoots should be shortened down to five or six eyes, in order to obtain a sufficient quantity of branches, to furnish the lower part of the wall or espalier; but the shoots ought not to be shortened, unless where there is a want of branches to fill a vacancy; therefore the less a knife is used to these trees, the better they will succeed; for, whenever the shoots are stopped, it occasions the buds immediately below the cut to send forth two or more shoots, whereby there will be a confusion of branches, and rarely any fruit is produced with this management.

The distance which the branches of Pears should be trained, must be proportioned to the size of their fruit; therefore such sorts, whose fruit are small, may be allowed five or six inches, but the larger sorts must not be less than seven or eight inches asunder. If this be duly observed, and the branches carefully trained horizontally as they are produced, there will be no occasion for so much cutting as is commonly practised on these trees, which, instead of checking their growth, does, on the contrary, cause them to shoot the stronger.

It is very surprising to read the tedious methods, which most of the writers on fruit-trees have directed for pruning these trees; for, by their prolix and perplexed methods, one would imagine they had endeavoured to render themselves as unintelligible as possible; and this, I am sure, may be affirmed, that it is next to impossible for a learner ever to arrive at

any tolerable skill in pruning by the tedious and perplexed directions which are published by Monsieur Quintiny, and those who have copied from him; for, as these have all set out wrong in the beginning, by allowing their trees less than half the distance which they should be planted, they have prescribed rules to keep them within that compass, which are the most absurd, and contrary to all reason, therefore should not be practised by those persons who are desirous of having plenty of fruit.

I shall therefore only lay down a few necessary directions for pruning and managing these trees, which shall be done in as few words as possible, that a learner may the more easily understand it, and which (together with proper observations) will be sufficient to instruct any person in the right management of them.

Pear-trees generally produce their blossom-buds first at the extremity of the last year's shoots, so that if these are shortened, the blossoms are cut off; but this is not all the damage, for (as I before said) this occasions the buds immediately below the cut to put forth two or more shoots, whereby the number of branches will be increased, and the tree crowded too much with wood; besides, those buds, which by this management produce shoots, would have only produced curlions or spurs, upon which the blossom-buds are produced, if the leading branch had not been shortened; therefore these should never be stopped, unless to furnish wood to fill a vacancy.

It is not necessary to provide a new supply of wood in Pear-trees, as must be done for Peaches, Nectarines, &c. which only produce their fruit upon young wood; for Pears produce their fruit upon curlions or spurs, which are emitted from branches which are three or four years old; which curlions continue fruitful many years, so that, where these trees have been skilfully managed, I have seen branches which have been trained horizontally upwards of twenty feet from the trunk of the tree, and have been fruitful their whole length. And if we do but carefully observe the branches of a healthy standard-tree, which has been permitted to grow without pruning, we shall find many that are ten or twelve years old, or more, which are very full of these curlions, upon which a good number of fruit is annually produced.

During the summer season these trees should be often looked over to train in the shoots, as they are produced, regularly to the wall or espalier, and to displace fore-right and luxuriant branches as they shoot out, whereby the fruit will be equally exposed to the air and sun, which will render them more beautiful and better tasted than when they are shaded by the branches; and by thus managing the trees in summer, they will always appear beautiful, and in winter they will want but little pruning.

Where Pear-trees are thus regularly trained without stopping their shoots, and have full room for their branches to extend on each side, there will never be any occasion for disbarking the branches, or cutting off the roots (as hath been directed by several writers on gardening;) which methods, however they may answer the intention for the present, yet will certainly greatly injure the trees, as must all violent amputations, which should ever be avoided as much as possible on fruit-trees; and this, I am sure, can never be wanted, where trees have been rightly planted, and regularly trained, while young.

The season for pruning these trees is any time after the fruits are gathered, until the beginning of March; but the sooner it is done after the fruit is gathered, the better, for reasons already given for pruning of Peach-trees; though indeed the deferring of these until spring, where there are large quantities of trees to prune, is not so injurious to them, as to some tender fruits; but if the branches are regularly trained in summer, and the luxuriant shoots rubbed off, there will be little left to do to them in winter.

All the sorts of Summer Pears will ripen very well either on standards, dwarfs, or espaliers, as will all Autumn Pears upon dwarfs or espaliers; but, where

a person is very curious in his fruit, I would always advise the planting them against espaliers, in which method they take up but little room in a garden, and, if they are well managed, appear very beautiful; and the fruit is larger and better tasted than those produced on dwarfs, as hath been already observed; but some of the Winter Pears must be planted against east, south-east, or south-west walls, otherwise they will not ripen well in England in bad seasons.

But although this may be the case with some of the late Winter Pears in very bad seasons, yet, in general, most sorts of them will ripen extremely well in all warm situations, when they are planted in espalier, and the fruit will be better flavoured than that which grows against walls, and will keep much longer good; for, as the heat against walls which are exposed to the sun will be very great at some times, and at others there will be little warmth, all fruit which grow near them, will be hastened unequally, and therefore is never so well flavoured as the same sorts are which ripen well in the open air; and all the fruit, which is ripened thus unequally, will decay much sooner than those which ripen gradually in the open air; therefore those Winter Pears which grow in espalier, may be kept six weeks longer than those which grow against walls, which is a very desirable thing; for to have plenty of these fruit at a season when it is very rare to find any other fruit to supply the table but Apples, is what all lovers of fruit must be greatly pleased to enjoy; which is what may be effected by planting many of the late sorts in espalier, where, although the fruit will not be so well coloured as those from the walls, yet they will be found exceeding good. When the *Beli de Chaumontelle* came first to England, the trees were planted in espalier, and some of them not on a very good soil, or in a warm situation, and yet from these trees I have eaten this Pear in great perfection in April, and sometimes it has kept till May; whereas, all those which have been since planted against walls ripen their fruit by the beginning of November, and are generally gone by the middle of December; nor are the latter so well tasted as those off the espaliers.

The *Virgoleuse* and *St. Germain*, as also the *Colmar*, are esteemed the most difficult sorts to ripen their fruit, yet these I have eaten in great perfection from espaliers, and often from standard-trees, where they grew upon a warm soil; but the fruit was much smaller on the standard-trees than those of the same sorts which grew against walls or espaliers, but they were full as well flavoured, and some of these sorts I have eaten good in April, which is two months later than they usually keep; but yet I would not advise the planting these late Pears in standard-trees, because they should hang very late on the trees in autumn, at which season the winds are generally very high; and these standard-trees being much exposed, the fruit is often blown off the trees before they are ripe; and those of them, which may hang on the trees, are frequently bruised by being forced against the branches by the winds, so that they seldom keep well. What I mentioned this for, is to prove, that these Pears will ripen very well without the assistance of a wall; so that if they are planted in espaliers where the trees are kept low, the fruit will not be so much exposed to the strong winds in autumn as those on the standards, therefore can be in no danger of the fruit coming to perfection; and as the trees in espaliers will be constantly pruned, and managed in the same manner as those against walls, the fruit will be as large on those trees; therefore, where a person has a warm situation and a kindly soil, I would not advise the being at an expence to build walls on purpose for Pears, but to plant them against espaliers: and where there is any one who is very curious in having plenty of these fruit, and will be at the expence to procure them, I should advise having a sufficient quantity of Reed mats made to fix up against the back of the espalier in the spring, when the trees are in blossom, which will screen them from

P Y R

from cold winds, and preserve the tender fruit until they are past danger, when the Reeds may be taken down, and put under a shed to preserve them from the weather; and if the autumn should prove bad, these Reeds may be fixed up again, which will forward the ripening of the fruit, and also prevent the winds from blowing down, and bruising it. These Reeds may be purchased for one shilling per yard, running measure, at six feet and a half high; and if they are carefully laid up, and kept from the weather, these Reeds will last seven or eight years, so that the expence will not be very great; and when the advantages which these are of to the fruit are considered, I believe no person will object to the use of them.

But after the fruit is set and growing, there will be farther care necessary in order to have the fruit good; for it is not enough to have preserved a good crop of fruit on the trees, and then leave them entirely to nature during the season of their growth, but there will require some skill and attendance on the trees to help nature, or supply the deficiency of seasons; for beside the pruning and training trees in the manner before directed, there will also be wanting some management of their roots, according to the nature of the soil, and the difference of seasons. In all strong land, where the ground is apt to bind very hard in dry weather, the surface of the borders should be now and then forked over to loosen the earth, which will admit the showers and large dews to penetrate and moisten the ground, and be of great service to the trees and fruit, and also prevent the growth of weeds. And if the soil is light and dry, and the season should prove hot and dry, there should be large hollows made round the stems of the trees to hold water; and into each of these there should be poured eight or nine pots of water, which should be repeated once in a week or ten days during the months of June and July, if the season should continue dry. There should also be some mulch laid over the surface of these hollows, to prevent the sun and air from drying the ground. Where this is practised, the fruit will be kept constantly growing, and prove large and plump; whereas, if this is omitted, the fruit will often be small, grow crooked, crack, and fall off from the trees. For if the fruit is once stunted in their growth, and rain should fall plentifully after, it will occasion a great quantity of fruit to fall off the trees, and those which remain to ripen will not keep so long as those which never receive any check in their growth; and it is from this cause, that some years the fruit in general decays before the usual time. For after it has been for some time stunted in its growth, and then the season proves favourable, whereby it receives a sudden growth, it becomes so replete with juice, as to distend the vessels too suddenly, so that they will not be firm, which occasions their decay; therefore it is always best to keep the fruit constantly in a growing state, whereby it will acquire a proper size, and be rendered better flavoured.

There will also be required some dressing to the ground near the fruit-trees; but this should be laid on in autumn, after the trees are pruned. This dressing should be different, according to the nature of the soil; if the land is warm and dry, then the dressing should be of very rotten dung, mixed with loam; and if this is mixed six or eight months before it is laid upon the borders, and three or four times turned over, it will be the better; as will also the mixture, if it is made with neat's or hog's dung, both which are colder than horse dung, so more proper for hot land. But in cold stiff land, rotten horse dung, mixed with light sandy earth, or sea-coal ashes, will be the most proper, as this will loosen the ground and add a warmth to it.

These dressings should be repeated every other year, otherwise the trees will not thrive so well, nor will the fruit be so good. For, notwithstanding what many persons have advanced to the contrary, yet experience

P Y R

is against them; for the finest fruit in England, both as to size and flavour, is produced on land which is the most dunged and worked. Therefore I would advise trenching the ground about the fruit-trees very well every winter, for I am sure they will find it answer their expectations who shall practise this method. And where the ground in the quarters is well dressed and trenched, the fruit-trees will partake of the benefit; for as the trees advance in their growth; so their roots are extended to a great distance from their stems; and it is chiefly from the distant roots that the trees are supplied with their nourishment; therefore dressing the borders only, will not be sufficient for fruit-trees which are old.

In gathering of Pears, great regard should be had to the bud which is formed at the bottom of the foot-stalk, for the next year's blossoms; which, by forcing off the Pear before it be mature, is many times spoiled; for while the fruit is growing, there is always a bud formed by the side of the foot-stalk upon the same spur, for the next year's fruit; so that when the Pears are ripe, if they are gently turned upward, the foot-stalk will readily part from the spur, without injuring the bud.

The season for gathering all Summer Pears is just as they ripen, for none of these will remain good above a day or two after they are taken from the tree; nor will many of the Autumn Pears keep good above ten days or a fortnight after they are gathered. But the winter fruits should hang as long upon the trees as the season will permit; for they must not receive the frost, which will cause them to rot, and render their juices flat and ill tasted; but if the weather continue mild until the end of October, it will then be a good season for gathering them in, which must always be done in dry weather, and when the trees are perfectly dry.

In the doing of this you ought carefully to avoid bruising them, therefore you should have a broad flat basket to lay them in as they are gathered; and when they are carried into the store-room, they should be taken out singly, and each sort laid up in a close heap on a dry place, in order to sweat, where they may remain for ten days or a fortnight; during which time the windows should be open to admit the air, in order to carry off all the moisture which is perspired from the fruit; after this, the Pears should be taken singly, and wiped dry with a woollen cloth, and then packed up in close baskets, observing to put some Wheat straw in the bottoms, and round the sides of the baskets, to prevent their bruising against the baskets. And if some thick soft paper is laid double or treble all round the basket, between the straw and the Pears, this will prevent the Pears from imbibing the musty taste which is communicated to them by the straw, when they are contiguous; which taste often penetrates through the skin so strongly, that when the fruit is pared, the taste will remain. You should also observe to put but one sort of fruit into a basket, lest by their different fermentations, they should rot each other; but if you have enough of one sort to fill a basket which holds two or three bushels, it will be still better. After you have filled the baskets, you must cover them over with Wheat straw very close, first laying a covering of paper two or three times double over the fruit, and fasten them down; then place these baskets in a close room, where they may be kept dry and from frost; but the less air is let into the room, the better the fruit will keep. It will be very necessary to fix a label to each basket, denoting the sort of fruit therein contained, which will save the trouble of opening them, whenever you want to know the sorts of fruit; besides, they ought not to be opened before their season to be eaten, for the oftener they are opened and exposed to the air, the worse they will keep. I do not doubt but this will be objected to by many, who imagine fruit cannot be laid too thin; for which reason, they make shelves to dispose them singly upon, and are very fond of admitting fresh air, whenever the weather is mild, supposing

supposing it very necessary to preserve the fruit; but the contrary of this is found true, by those persons who have large stocks of fruit laid up in their store-houses in London, which remain closely shut up for several months, in the manner before related; and when these are opened, the fruit is always found plumper and sounder than any of those fruits which were preserved singly upon shelves, whose skins are always shrivelled and dry. For (as Mr. Boyle ob-

serves) the air is the cause of putrefaction; and, in order to prove this, that honourable person put fruits of several kinds into glasses where the air was exhausted, in which places they remained sound for several months, but, upon being exposed to the air, rotted in a very short time after; which plainly shews the absurdity of the common method now used, to preserve fruit.

QUAMOCLIT. See IPOMOEIA.

QUERCUS. Tourn. Inst. R. H. 582. tab. 349. Lin. Gen. Plant. 949. [so called of *ῥυχῶ*, Gr. to make rough; either from the roughness of its bark, or because of its austerity.] The Oak-tree; in French, *Chêne*.

The CHARACTERS are,

It hath male and female flowers on the same tree; the male flowers are disposed in a loose catkin; these have an empalement of one leaf, divided into four or five segments; they have no petals, but many short stamina, terminated by large twin summits. The female flowers which sit close to the buds, have a hemispherical thick empalement of one leaf, which is rough and entire, almost hiding the flower, which has no petal, but a small oval germen, supporting a single five-pointed style, crowned by single permanent stigmas. The germen afterward becomes an oval nut (or acorn) with a thick cover, having one cell, whose base is fixed into the empalement or cup.

This genus is ranged in the eighth section of Linnaeus's twenty-first class, which includes those plants which have male and female flowers on the same plant, whose male flowers have many stamina. He joins to this genus the *Ilex* and the *Suber* of Tournefort, whose characters are the same as the Oak.

The SPECIES are,

1. *Quercus (Robur)* foliis deciduis oblongis, supernè latoribus sinibus acutioribus, angulis obtusis petiolatis glandibus sessilibus. Oak with oblong deciduous leaves, broader toward the top, having acute indentures, with obtuse angles, which have long foot-stalks, and acorns sitting close to the branches. *Quercus latifolia* mas, quæ brevi pediculo est. C. B. P. 419. Broad-leaved male Oak, the fruit of which has short foot-stalks, or common Oak.
2. *Quercus (Femina)* foliis deciduis oblongis obtusis, pinnato sinuatis petiolis brevissimis, pedunculis glandorum longissimis. Oak with oblong, obtuse, deciduous leaves, which are winged, sinuated, and have very short foot-stalks, with a fruit growing upon long foot-stalks. *Quercus cum longo pediculo*. C. B. P. 429. Oak with long foot-stalks to the Acorn.
3. *Quercus (Sempervirens)* foliis oblongis sinuatis obtusis perennantibus, pedunculis glandorum longissimis. Oak with oblong, obtuse, indented leaves which are evergreen, having very long foot-stalks to the Acorns. *Quercus latifolia perpetuo virens*. C. B. P. 420. Broad leaved evergreen Oak.
4. *Quercus (Ilex)* foliis oblongis obtusè dentatis, fructibus sessilibus conglomeratis. Dwarf Oak with oblong, obtuse, crenated leaves, and fruit growing in clusters having none of the stalks. *Quercus humilis* gallis bi-

Q U E

nis ternis aut plurimis simul junctis. C. B. P. 420. Dwarf Oak with galls growing together by pairs, by threes, or in larger clusters.

5. *Quercus (Cerris)* foliis oblongis lyrato-pinnatifidis, laciniis transversis acutis, subtus subtomentosis. Lin. Sp. Plant. 997. Oak with oblong leaves which are lyre-shaped, wing-pointed, and have transverse acute jags which are downy on their under side. *Quercus calyce hispido, glande minore*. C. B. P. 420. Oak with prickly cups and smaller Acorns.
6. *Quercus (Esculus)* foliis pinnato-sinuatis lævibus fructibus sessilibus. Prod. Leyd. 80. Oak with smooth wing-indented leaves, and fruit sitting close to the branches. *Quercus parva* five *Phagus Græcorum* & *Esculus Plinii*. C. B. P. The small Oak or Phagus of the Greeks, and the Esculus of Pliny, commonly called the cut-leaved Italian Oak.
7. *Quercus (Ægilops)* foliis ovato-oblongis glabris, serrato dentatis. Lin. Sp. Plant. 1414. Oak with oblong, oval, smooth, sawed, indented leaves. *Quercus calyce echinato, glande majore*. C. B. P. 420. Oak with a prickly cup and a larger Acorn.
8. *Quercus (Rubra)* foliis obtusè sinuatis setacco-mucronatis. Lin. Sp. Plant. 996. Oak with obtuse sinuated leaves, terminated by bristly points. *Quercus Esculi divifurâ, foliis amplioribus aculeatis*. Pluk. Alm. 309. tab. 54. fig. 4. Oak with broad spiny leaves, which are divided like the Esculus.
9. *Quercus (Prinus)* foliis obovatis utrinque acumina-tis sinuato-serratis, denticulis rotundatis uniformibus. Hort. Cliff. 448. Oak with oblong oval leaves which are pointed on both sides, and have sawed sinuses, with uniform roundish indentures. *Quercus castaneæ foliis pro-cera arbor Virginiana*. Pluk. Alm. 309. The American Chestnut-leaved Oak.
10. *Quercus (Nigra)* foliis cuneiformibus obsoletè trilobis. Flor. Virg. 117. Oak with wedge-shaped leaves, having three worn-out lobes. *Quercus folio non serrato in summitate quasi triangulo*. Catelb. Car. 1. p. 20. The Black Oak.
11. *Quercus (Alba)* foliis oblique pinnatifidis, sinibus angulisque obtusis. Lin. Sp. Plant. 996. Oak with oblique many-pointed leaves, having obtuse sinuses and angles. *Quercus alba Virginiana*. Catelb. Car. 1. p. 21. tab. 21. The white Oak of Virginia.
12. *Quercus (Phellos)* foliis lanceolatis integerrimis glabris. Flor. Virg. 149. Oak with spear-shaped, entire, smooth leaves. *Quercus foliis oblongis non sinuatis*. Catelb. Car. 1. p. 17. The Willow leaved Oak.
13. *Quercus (Ilex)* foliis oblongo-ovatis subtus tomentosis integerrimis. Prod. Leyd. 81. Oak with oblong, oval, entire leaves, which are downy on their under side. *Ilex folio*

folio angusto non ferrato. C. B. P. 424. *The narrow-leaved evergreen Oak.*

14. *QUERCUS (Gramuntia)* foliis oblongo-ovatis sinuato-spinosis subtus tomentosis, glandibus pedunculatis. Sauv. Monsp. 96. *Evergreen Oak with oblong, oval, prickly, indented leaves, which are woolly on their under side, and bears Acorns with foot-stalks.* Ilex folio agrifolii. Bot. Monsp. 140. *The Holly-leaved evergreen Oak.*

15. *QUERCUS (Coccifera)* foliis ovatis indivisis, spinosodentatis glabris. Prod. Leyd. 80. *Oak with oval, undivided, smooth leaves, which are prickly and indented.* Ilex aculeata, cocciglandifera. C. B. P. 425. *Prickly Kermes Oak.*

16. *QUERCUS (Virginiana)* foliis lanceolato-ovatis integerrimis petiolatis sempervirentibus. *Oak with spear-shaped, oval, entire leaves, which are evergreen, and have foot-stalks.* Quercus sempervirens foliis oblongis non sinuatis. Banist. *Evergreen Oak with oblong leaves which are not sinuated, commonly called Live Oak in America.*

17. *QUERCUS (Suber)* foliis ovato-oblongis indivisis serratis subtus tomentosis, cortice rimoso fungoso. Hort. Cliff. 448. *Oak with oval, oblong, undivided leaves, which are sawed and woolly on their under side, and have a fungous cleft bark.* Suber latifolium perpetuo virens. C. B. P. 424. *The broad-leaved evergreen Cork-tree.*

The first sort here mentioned, is the most common Oak of this country, which is so well known as to need no description; the leaves of this have pretty long foot-stalks, and the Acorns have none, but sit close to the branches.

The second sort is not so common here as the first, but in the wilds of Kent and Sussex I have seen many large trees of this kind. The leaves of this are not so deeply sinuated as those of the first, nor are they so irregular, but the indentures are opposite, like the lobes of winged leaves; these have scarce any foot-stalks, but sit close to the branches; the Acorns stand upon very long foot-stalks, in which they differ from the common sort. The timber of this sort is accounted better than that of the first, and the trees when growing have a better appearance. These have been generally supposed to be feminal varieties, which have accidentally come from Acorns of the same trees; I was long of this opinion myself, but having lately seen some young trees with Acorns upon them, which were raised from Acorns of the second sort, and finding they retain their difference, I am inclined to believe they are different.

The third sort grows upon the Apennines, and also in Swabia and Portugal. The leaves of this are broader, and not so deeply sinuated as those of the common Oak; they are of a lighter green on their upper side, and pale on their under; they have very short foot-stalks, and their points are obtuse; the Acorns have very long foot-stalks, which frequently sustain three or four growing in a cluster.

The fourth sort grows in the south of France and Italy; this is a low bushy Oak, which rises but six or seven feet high, sending out many slender branches the whole length, garnished with oblong leaves which are obtusely indented; they are about three inches long, and one and a half broad, standing upon slender foot-stalks; the Acorns are small and grow in clusters, and the galls grow three or four together.

The fifth sort grows in Burgundy; the leaves of this are oblong and pointed, and are frequently indented in the middle like a lyre; they are jagged and acute-pointed, a little hoary on their under side, standing upon slender foot-stalks. The Acorns are small, and have rough prickly cups.

The sixth sort grows naturally in Spain and Italy; the leaves of this tree are smooth, and deeply sinuated like winged leaves; some of the sinuses are obtuse, and others end in acute points; they have very short foot-stalks; the branches are covered with a purplish bark when young; the Acorns are long and slender, the cups rough and a little prickly, sitting close to the branches. The Acorns of this sort are sweet, and are

frequently eaten by the poor in the south of France, who in times of scarcity grind them and make bread with the flour.

The seventh sort grows naturally in the Levant, from whence the Acorns are annually brought to Europe, where they are used for dyeing; these are called Velani, and the tree Velanida by the Greeks. It is one of the fairest species of Oak in the world: the trunk of this rises as high as the common Oak; the branches extend very wide on every side, and are covered with a grayish bark, intermixed with brown spots; the branches are closely garnished with oblong oval leaves, about three inches long, and almost two broad, which are deeply sawed on their edges; most of the saws or teeth turn backward, and terminate in acute points. The leaves are stiff, of a pale green on their upper side, and downy on their under; the Acorns have very large scaly cups which almost cover them; the scales are ligenous and acute-pointed, standing out a quarter of an inch; some of the cups are as large as middling Apples.

The eighth sort grows naturally in Virginia, and in other parts of North America. This arrives to a large size in the countries where it naturally grows; the bark is smooth, of a grayish colour, but that of the younger branches is darker; the leaves are six inches long, and two and a half broad in the middle, where they are broadest; they are obtusely sinuated, each sinus ending with a bristly point, of a bright green, standing upon short foot-stalks. The leaves continue their verdure very late in autumn, so that unless hard frost comes on early, they do not fall till near Christmas, and they do not change their colour long before. The Acorns of this sort are a little longer, but not so thick as those of the common Oak.

The ninth sort grows naturally in North America; of this there seems to be two kinds, one of which grows to a much larger size than the other, though this may be occasioned by the soil in which they grow; for the largest sort grows in the rich low lands, where it becomes the largest tree of any of the Oaks in those countries. The wood is not of a fine grain, but is very serviceable; the bark is gray and scaly; the leaves are five or six inches long, and two inches and a half broad in the middle, indented on the edges, and have many transverse veins running from the midrib to the borders; they are of a bright green, and so nearly resemble those of the Chestnut tree, as scarcely to be distinguished from it. The Acorns of this sort are very large, and their cups are short. The leaves of the other variety are not so large, nor so strongly veined, and the Acorns are smaller and a little longer, which may arise from the soil.

The tenth sort grows naturally on poor land in most parts of North America, where it never grows to a large size, and the wood is of little value. The bark is of a dark brown colour; the leaves are very broad at the top, where they have two waved indentures, which divide them almost into three lobes; they diminish gradually to their base, where they are narrow; they are smooth, of a lucid green, and have short foot-stalks. The Acorns are smaller than those of the common Oak, and have short cups.

The eleventh sort grows naturally in North America, where the wood is esteemed preferable to any of their other sorts for building, being much more durable than any of them. The bark of this tree is grayish, the leaves are of a light green six or seven inches long, and four broad in the middle; they are regularly indented almost to the midrib; the indentures are obtuse, and have short foot-stalks. The Acorns of this greatly resemble those of the common Oak.

The twelfth sort grows naturally in North America, where they distinguish two sorts; one of them is called the Highland Willow Oak, which grows upon poor dry land; the leaves are of a pale green and entire, shaped like those of the Willow tree. The Acorns are very small, but have pretty large cups.

The other grows in low moist land, and rises to a much greater height; the leaves are longer and nar-

Q U E.

rower, and the Acorns are of the same size and shape, so that I suspect their difference is owing to the soil in which they grow.

The thirteenth sort is generally known by the title of Ilex, or evergreen Oak; of this there are several varieties, which differ greatly in the size and shape of their leaves; but these will all arise from Acorns of the same tree, as I have several times experienced; nay, the lower and upper branches of the same tree are frequently garnished with leaves, very different in size and shape from each other; those on the lower branches being much broader, rounder, and their edges indented and set with prickles, but those on the upper are long, narrow, and entire; so that I verily believe they are all but one species, except the Kermes Oak, which is undoubtedly a distinct sort. The leaves of the Ilex are from three to four inches long, and one broad near the base, gradually lessening to a point; they are of a lucid green on their upper side, but whitish and downy on their under, and are entire, standing upon pretty long foot-stalks; these remain green all the year, and do not fall till they are thrust off by young leaves in the spring. The Acorns are smaller than those of the common Oak, but of the same shape.

The fourteenth sort is supposed to be a different species, but of this I much doubt, having raised some plants from the Acorns of the thirteenth, whose leaves are so like those of this, as not to be distinguished from them; these are shorter and broader than the other, and approach in shape to those of the Holly-tree, and are also set with prickles on their edges.

The fifteenth sort is the Oak, from which the kermes, or what is called scarlet grain is collected, which is an insect that harbours on this tree. It grows naturally in Provence and Languedoc, where it is known by the title d'Avaux. This is of small growth, seldom rising above twelve or fourteen feet high, sending out branches on every side the whole length, so as to form a bushy shrub; the leaves are oval and undivided; they are smooth on their surface, but indented on their edges, which are armed with prickles like those of the Holly-tree. The Acorns are smaller than those of the common Oak.

The sixteenth sort grows naturally in Carolina and Virginia, where it rises to the height of forty feet. The grain of the wood is hard, tough, and coarse; the bark is grayish; the leaves are ovally spear-shaped, about three inches long and one and a half broad, entire, and of a dark green, standing upon short foot-stalks; they are of a thick consistence, and continue green all the year. The Acorns are small, oblong, and have short cups; they are very sweet, so are eaten by the Indians, who lay them up in store for the winter; they also draw a very sweet oil from them, little inferior to that of sweet Almonds. This is called the Live Oak in America.

The seventeenth sort is the tree whose bark is the cork; of this there are two or three varieties, viz. one with a broad, another with a narrow leaf, which are evergreen; and there is one or two which cast their leaves in autumn, but the broad-leaved evergreen is the most common; the other may probably be only varieties arising by accident. The leaves of this are entire, of an oblong oval, about two inches long, and one and a quarter broad, sawed on their edges, and have a little down on their under sides; their foot-stalks are very short; these leaves continue green through the winter till the middle of May, when they generally fall off just before the new leaves come out, so that the trees are very often almost bare for a short time. The Acorns are very like those of the common Oak.

The exterior bark of this tree is the cork; this is taken off from the trees every eight or ten years, but there is an interior bark which nourishes the trees, so that the stripping off the outer is so far from injuring them, that it is necessary to continue the trees; for those whose bark are not taken off, seldom last longer than fifty or sixty years in health; whereas the trees

Q U E.

which are barked every eight or ten years, will live a hundred and fifty years and more. The bark of the young tree is porous and good for little, however it is necessary to take it off when the trees are twelve or fifteen years old, without which the bark will not be good, and after eight or ten years, the bark will be fit to take off again; but this second peeling is of little use, but the third peeling the bark will be in perfection, and will continue so many years, for the best cork is taken from the old trees. The time of year for stripping off this bark is in July, when the second sap flows plentifully; this is performed with an instrument, like that used for disbarking Oaks. The ashes of burnt cork mixed with fresh butter, and made into an ointment, is much recommended for the piles.

All the sorts of Oaks are propagated by sowing their Acorns, and the sooner they are put into the ground after they are ripe, the better they will succeed; for they are very apt to sprout where they are spread thin, and if they are laid in heaps, they ferment and rot in a little time; therefore the best season for sowing them is in the beginning of November, by which time they will be fallen from the trees.

I shall first give some directions for raising the several sorts of Oaks in a nursery, which are intended to be planted out for ornament, where their timber is not to be regarded. These Acorns may be sown in beds about four feet wide, with paths of two feet broad between them; in these beds there may be four rows sown, at about nine inches distance from each other; when the beds are marked out, there should be drills drawn with a hoe in a strait line, into which the Acorns should be dropped at about two or three inches distance; then they must be carefully covered over with the earth two inches thick, leaving none of them uncovered, which might tempt the vermin, for if they once find them out, they will make sad havock of the Acorns.

In the spring, when the plants begin to appear, you must carefully clear them from weeds; and if the season proves dry, you should refresh them now and then with a little water, which will greatly promote their growth. In these beds the plants should remain until the following autumn (observing constantly to keep them clear from weeds;) at which time you should prepare a spot of good fresh earth (in size proportionable to the quantity of plants,) which should be well trenched and levelled; then toward the middle or latter end of October, you should carefully take up the plants, so as not to injure their roots, and plant them out in rows three feet asunder, and eighteen inches distance plant from plant; observing never to suffer the plants to abide long out of the ground, because their roots would dry and endanger their growth.

When the plants have taken root in this nursery, they will require little more care than to keep them clear from weeds, and dig the ground between the rows every spring; in doing of which, you should cut off such roots as extend very far from the trunk of the trees, which will render them better for transplanting again; you should also prune off such side-branches as extend themselves very far, and would retard the upright shoot; but you should by no means cut off all the small lateral branches, some of which are absolutely necessary to be left on, to detain the sap for the augmentation of the trunk; for I have often observed, where trees have been thus closely pruned, that their heads have overgrown their bodies, so that they have bent downward and become crooked.

When these trees have remained in the nursery three or four years, they will then be large enough to transplant to the places where they are to remain; for it is not proper to let them grow very large before they are planted out, because these are very hazardous trees to remove when old, or after they have taken deep root.

Q U E

The season for this work is (as I said before) in the autumn; at which time, if they are carefully taken up, there will be little danger of their succeeding. In transplanting these trees, you should by no means cut their heads, which is too much practised; all that should be done, must be only to cut off any bruised or ill-placed branches, which should be taken off close to the place where they are produced; but there can be no greater injury done to these trees, than to shorten their shoots; for when the leading bud (which is absolutely necessary to draw and attract the nourishment) is taken off, the branch often decays entirely, or at least down to the next vigorous bud.

The trees thus raised and managed, will, (if planted in a proper soil) grow to a considerable magnitude, and are very proper for a wilderness in large gardens, or to plant in clumps in parks, &c. but if they are designed for timber, it is much the better method to sow the Acorns in the places where they are to remain; in order to which, you should provide yourself in autumn with a sufficient quantity of Acorns, which should be always taken from strait, upright, vigorous growing trees; these should be gathered from under the trees as soon as may be after they are fallen; and, if possible, in a dry time, laid thin in some open room to dry; after which they may be put into dry sand, and preserved in a dry place until the beginning of November, when you should prepare the ground for planting them.

The directions before given are designed only for small plantations in a garden or park, which are only for pleasure; but where these trees are cultivated with a view to profit, the Acorns should be sown where the trees are designed to grow; for those which are transplanted will never grow to the size of those which stand where they are sown, nor will they last near so long sound. For in some places, where these trees have been transplanted with the greatest care, and they have grown very fast for several years after, yet they are now decaying, when those which remain in the place where they came up from the Acorns, are still very thriving, and have not the least sign of decay. Therefore, whoever designs to cultivate these trees for timber, should never think of transplanting them, but sow the Acorns on the same ground where they are to grow; for the timber of all those trees which are transplanted, is not near so valuable as that of the trees from Acorns. I shall therefore add some plain directions for sowing Acorns, and managing young trees during their minority, until they are out of danger, and require no farther care.

The first thing to be done is, that of fencing the ground very well, to keep out cattle, hares, and rabbits; for if either of these can get into the ground, they will soon destroy all the young trees. Indeed they will in a few years grow to be out of danger from hares and rabbits, but it will be many years before they will be past injury from cattle, if they are permitted to get into the plantation, therefore durable fences should be put round the ground: if in the beginning a pale fence is made about the land, which may be close at the bottom and open above, and within the pale a Quick-hedge planted, this will become a good fence by the time the pale decays, against all sorts of cattle; and then the trees will have got above the reach of hares and rabbits, so that they cannot injure them, for the bark of the trees will be too hard for them to gnaw.

After the ground is well fenced, it should be prepared, by ploughing it three or four times, and after each ploughing to harrow it well, to break the clods, and cleanse the ground from Couch, and the roots of all bad weeds. Indeed if the ground is green sward, it will be better to have one crop of Beans, Peas, or Turneps off the ground, before the Acorns are sown, provided these crops are well hoed to stir the surface and destroy the weeds; for if this is observed, the crop will mend and improve the land for sowing; but in this case the ground should be ploughed as soon as possible, when the crop is taken off, to prepare it

Q U E

for the Acorns, which should be sown as soon as may be after the Acorns are ripe; for although these may be preserved in sand for some time, yet they will be apt to sprout; and if so, the shoots are in danger of being broken and spoiled; therefore I should advise sowing early, which is certainly the best method.

In making choice of the Acorns, all those should be preferred, which are taken from the largest and most thriving trees; and those of pollard-trees should always be rejected, though the latter are generally the most productive of Acorns, but those of the large trees commonly produce the strongest and most thriving plants.

The season for sowing the Acorns being come, and the ground having been ploughed and levelled smooth, the next work is to sow the Acorns, which must be done by drawing drills across the ground, at about four feet asunder, and two inches deep, into which the Acorns should be scattered at two inches distance. These drills may be drawn either with a drill plough, or by hand with a hoe; but the former is the most expeditious method, therefore in large plantations should be preferred. In drawing the drills, if the land has any slope to one side, these should be made the same way as the ground slopes, that there may be no stoppage of the wet by the rows of plants crossing the hanging of the land. This should be particularly observed in all wet ground, or where the wet is subject to lie in winter, but in dry land it is not of much consequence. When the Acorns are sown, the drills should be carefully filled in, so as to cover the Acorns securely; for if any of them are exposed, they will entice the birds and mice; and if either of these once attack them, they will make great havock with them.

The reason of my directing the drills to be made at this distance, is for the more convenient stirring the ground between the rows, to keep the young plants clear from weeds; for if this is not carefully done, it cannot be expected that the young plants should make much progress; and yet this is generally neglected by many who pretend to be great planters, who are often at a large expence to plant, but seldom regard them after; so that the young plants have the difficulty to encounter the weeds, which are frequently four or five times the height of the plants, and not only shade and draw them, but also exhaust all the goodness of the ground, and consequently starve the plants. Therefore, whoever hopes to have success in their plantations, should determine to be at the expence of keeping them clean for eight or ten years after sowing, by which time the plants will have obtained strength enough to keep down the weeds; the neglecting of this has occasioned so many plantations to miscarry, as are frequently to be met with in divers parts of England.

About the middle of April the young plants will appear above ground; but before this, if the ground should produce many young weeds, it will be good husbandry to scuffle the surface over with Dutch hoes, in a dry time, either the latter end of March or the beginning of April, to destroy the weeds, whereby the ground will be kept clean until all the plants are come up so as to be plainly discerned; by which time it may be proper to hoe the ground over again, for by doing it early, while the weeds are small, a man will perform more of this work in one day than he can in three or four when the weeds are grown large; besides, there will be great hazard of cutting off or injuring the young plants when they are hid by the weeds; and small weeds being cut, are soon dried up by the sun; but large weeds often take fresh root and grow again, especially if rain should fall soon after, and then the weeds will grow the faster for being stirred; therefore it is not only the best method, but also the cheapest husbandry, to begin cleaning early in the spring, and to repeat it as often as the weeds are produced.

The first summer, while the plants are young, it will be the best way to perform these hoeings by hand, but

but afterward it may be done with the hoe-plough; for as the rows are four feet asunder, there will be room enough for this plough to work; and as this will stir and loosen the ground, it will be of great service to the plants; but there will require a little hand-labour where the plough is used, in order to destroy the weeds, which will come up in the rows between the plants; for these will be out of the reach of the plough, and if they are not destroyed, they will soon overgrow and bear down the young plants.

After the plants have grown two years, it will be proper to draw out some of them, where they grow too close; but in the doing of this, great care should be had not to injure the roots of those left; for as the plants which are drawn out are only fit for plantations designed for pleasure, so these should not be so much regarded in their being removed, as to sacrifice any of those which are designed to remain. In the thinning of these plantations, the plants may at the first time be left about one foot asunder, which will give them room enough to grow two or three years longer, by which time it may be easy to judge which are likely to make the best trees; therefore these may be then fixed on as standards to remain, though it will be proper to have a greater number at this time marked than can be permitted to grow, because some of them may not answer the expectation; and as it will be improper to thin these trees too much at one time, so leaving double the number intended at the second thinning will not be amiss. Therefore, if they are then left at about four feet distance in the rows, they will have room enough to grow three or four years longer; by which time, if the plants have made good progress, their roots will have spread over the ground, therefore it will be proper to take up every other tree in the rows. But by this I do not mean to be exact in the removing, but to make choice of the best plants to stand, which ever rows they may be in, or if they should not be exactly at the distance here assigned; all that is designed here, is to lay down general rules, which should be as nearly complied with as the plants will permit; therefore, every person should be guided by the growth of the trees in the performance of this work.

When the plants have been reduced to the distance of about eight feet, they will not require any more thinning. But in two or three years time, those which are not to remain will be fit to cut down, to make stools for under-wood; and those which are to remain, will have made such progress as to become a shelter to each other; for this is what should be principally attended to, whenever the trees are thinned; therefore in all such places as are much exposed to the wind, the trees should be thinned with great caution and by slow degrees; for if the air is let too much at once into the plantation, it will give a sudden check to the trees, and greatly retard their growth; but in sheltered situations, there need not be so great caution used as in those places, for the plants will not be in so much danger of suffering.

The distance which I should chuse to allow to those trees which are designed to remain for timber is, from twenty-five to about thirty feet, which will not be too near, where the trees thrive well; in which case their heads will spread, so as to meet in about thirty or thirty-five years; nor will this distance be too great, so as to impede the upright growth of the trees. This distance is intended, that the trees should enjoy the whole benefit of the soil; therefore, after one crop of the under-wood, or at the most two crops are cut, I would advise the stubbing up the stools, that the ground may be entirely clear, for the advantage of the growing timber, which is what should be principally regarded; but in general, most people have more regard for the immediate profit of the under-wood than the future good of the timber, and frequently by so doing spoil both; for if the under-wood is left after the trees have spread so far as that their heads meet, the under-wood will not be of

much worth; and yet, by their stools being left, they will draw away a great share of nourishment from the timber-trees, and retard them in their progress.

The soil in which the Oak makes the greatest progress, is a deep rich loam, in which the trees grow to the largest size; and the timber of those trees which grow upon this land, is generally more pliable than that which grows on a shallower or drier ground, but the wood of the latter is much more compact and hard. Indeed there are few soils in England, in which the Oak will not grow, provided there is proper care taken in their cultivation, though this tree will not thrive equally in all soils; but yet it might be cultivated to a national advantage upon many large wastes, in several parts of England, as also to the great profit of the estates where these tracts of land now lie uncultivated, and produce nothing to the owner. And should the present temper of destroying the timber of England continue in practice some years longer, in the same degree which it has for some years past, and as little care taken to raise a supply, this country which has been so long esteemed for its naval strength, may be obliged to seek for timber abroad, or be content with such a naval strength, as the poor remains of some frugal estates may have left growing; for as to the large forests, from whence the navy has been so long supplied, a few years will put an end to the timber there; and how can it be otherwise, when the persons to whose care these are committed, reap an advantage from the destruction of the timber?

Before I quit this subject, I must beg leave to take notice of another great evil, which is of so much consequence to the public, as to deserve their utmost attention; which is, that of cutting down the Oaks in the spring of the year, at the time when the sap is flowing. This is done for the sake of the bark, which will then easily peel off; and for the sake of this, I think, there is a law, whereby people are obliged to cut down their timber at this season. But by so doing, the timber is not half so durable as that which is fallen in the winter, so that those ships, which have been built of this spring-cut timber, have decayed more in seven or eight years, than others which were built with timber cut in winter; have done in twenty or thirty. And this our neighbours the French have experienced, and therefore have wisely ordered, that the bark should be taken off the trees standing, at the proper time, but the trees are left till the next, and sometimes until the second winter, before they are cut down; and the timber of these are found to be more durable and better for use, than that of any trees which have not been peeled. Therefore I wish we were wise enough to copy after them in those things which are for public good, rather than to imitate them in their follies, which has been too much the fashion of late years.

QUICK. By the word Quick is generally understood all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges; but, in the more strict sense of this word, it is generally applied to the Hawthorn, or *Mespilus Sylvestris*; under which name the young plants or sets, are commonly sold by the nursery-gardeners, who raise them for sale.

In the choice of these sets, those which are raised in the nursery, are to be preferred to such as are drawn out of the woods, because the latter have seldom good roots; though as they are larger plants than are commonly to be had in the nursery, many people prefer them on that account; but from long experience I have found, that those hedges which have been planted with young plants from the nursery, have always made the best hedges. Indeed, if persons would have patience to wait for these from seed, and to sow the Haws in the place where the hedge is designed, these unremoved plants will make a much stronger and more durable fence, than those which are transplanted; but I am aware that most people will be for condemning this practice, as tedious in raising; but if the same

Q U I

are buried one year in the ground, to prepare them for vegetation before they are sown, it will not be so long before this will become a good fence, as is generally imagined. Nay, from some trials of this kind, which I have made, I have found, that those plants which have remained where they came up from seed, have made such progress as to overtake, in six years, plants of two years growth, which were transplanted at the time when these seeds were sown.

And if the hedges are raised from seed, it will not be amiss to mix Holly berries with the Haws; and if so, these berries should also be buried one year, to prepare them, so that then both will come up together the following spring; and this mixture of Holly with the Quick, will not only have a beautiful appearance in the winter, but will also thicken the hedge at the bottom, and make it a better fence.

But where the hedge is to be planted, the sets should not be more than three years old from the Haws; for when they are older, their roots will be hard and woody; and as they are commonly trimmed off before the sets are planted, so they very often miscarry; and such of them as do live, will not make so good progress as younger plants, nor are they so durable; for these plants will not bear transplanting so well as many others, especially when they have stood long in the seed-bed unremoved.

The method of planting, as also of plashing and pruning of these hedges, having been fully explained under the article of HEDGES, I shall not repeat that here, but shall only beg leave to add the method which is prescribed by Thomas Franklin, Esq; which he had long practised in planting of these hedges, which is as follows:

He first set out the ground for ditches and Quick ten feet in breadth; he subdivided that, by marking out two feet and a half on each side (more or less at pleasure) for the ditches, leaving five in the middle between them; then digging up two feet in the midst of those five feet, he planted the sets in; which although it required more labour and charge, he says, he found it repaid the cost. This done he began to dig the fosses, and to set up one row of turfs on the outside of the said five feet; namely, one row on each side thereof, the green side outmost, a little reclining, so as the Grass might grow.

After this, returning to the place he began at, he ordered one of the men to dig a spit of the under-turf mould, and lay it between the turfs placed edgewise, as before described, upon the two feet, which was purposely dug in the middle; and prepared for the sets, which the planter set with two Quicks upon the surface of the earth almost upright, whilst another workman laid the mould forwards about twelve inches, and then set two more, and so continued.

This being finished, he ordered another row of turfs to be placed on each side upon the top of the former, and filled the vacancy between the sets and turfs as high as their tops; always leaving the middle, where the sets were planted, hollow, and somewhat lower than the sides of the banks by eight or ten inches, that the rain may descend to their roots; which is of great advantage to their growth, and by far better than by the old method, where the banks are made too much sloping; and the roots of the sets are seldom wetted, even in a moist season, the summer following; but if it prove dry, many of the sets, especially the late planted, will perish; and even few of those that had been planted in the beginning of April (the summer happening to be somewhat dry) elapsed.

The planting being thus advanced, the next care is fencing, by setting a hedge of about twenty inches high upon the top of the bank on each side thereof, leaning a little outwards from the sets, which will protect them as well (if not better) than a hedge of three feet or more, standing on the surface of the ground; for as these are raised with the turfs and fosses about twenty inches, and the hedge about twenty

Q U I

inches more, it will make three feet four inches, so as no cattle can approach the dead hedge to prejudice it, unless they set their feet in the ditch itself, which will be at least a foot and a half deep; and from the bottom of the foss to the top of the hedge, about four feet and a half, which they can hardly reach over to crop the Quick, as they might in the old way; and besides, such a dead hedge will endure a year longer.

He says, he had a hedge which had stood five years; and though nine or ten feet were sufficient for both ditches and banks, yet where the ground is but indifferent, it is better husbandry to take twelve feet, which will allow of a bank at least six feet broad, and gives more scope to place the dead hedges farther from the sets, and the ditches being shallow, will in two years time graze.

As to the objection, that taking twelve feet wastes too much ground, he affirms, that if twelve feet in breadth be taken for a ditch and bank, there will no more ground be wasted than by the common way; for in that a Quick is rarely set, but there are nine feet between the dead hedges, which is entirely lost all the time of fencing; whereas with double ditches, there remain at least eighteen inches on each side where the turfs were set on edge, that bear more Grass than when it lay on the flat.

But, admitting it did totally lay waste three feet of ground, the damage would be very inconsiderable; since forty perches, in length, two hundred and twenty yards will make perches 7, 25, 9, or 7 poles $\frac{1}{2}$; which at 13s. and 4d. the acre, amounts not to 7d. $\frac{1}{2}$ per annum.

Now that this is not only the best, but cheapest way of Quick-setting, will appear by comparing the charge of both.

In the usual way, the charge of a three feet ditch is 4d. per pole, the owner providing sets; if the workman finds them, he will have for making the said ditch and setting them, 8d. per pole; and for hedging, 2d. that is, for both sides, 4d. the pole; which renders the charge of hedging, ditching, and sets, 12d. the pole; that is, for forty rods in length 40s.

Then one load of wood out of the copse costs (with the carriage, though but two or three miles distance) 10s. which will seldom hedge above eight poles (single hedge;) but allowing to do ten, to fence forty poles, there must be at least eight loads of wood, which costs 4l. making the whole expence for ditching, fencing, and setting forty poles, to be 6l. reckoning with the least; for scarce any will undertake to do it for less than 3s. 6d. per pole, and then the forty poles cost 7l.

Whereas with double ditches, both of them, with the plants included, will be done for 8d. the pole, and the husbandman get as good wages as with the single ditch (for though the labour about them is more, yet the making the table is saved,) which costs 1l. 6s. 8d. and the hedges being low, they will make better wages at hedging for a penny a pole, than at 2d. for common hedges, which comes to 6s. 8d. for hedging forty poles on both sides. Thus one load of wood will fence thirty poles at least, and forty hedged with two thirds of wood less than in the other way, and cost but 1l. 6s. 8d. which makes the other whole charge of sets, ditching, fencing, and wood, but 3l.

QUICK-BEAM. See *SORBUS SYLVESTRIS*.

QUINCE-TREE. See *CYDONIA*.

QUINCUNX ORDER is a plantation of trees, disposed originally in a square, consisting of five trees, one at each corner, and a fifth in the middle, which disposition, repeated again and again, forms a regular grove, wood, or wilderness, and, when viewed by an angle of the square or parallelogram, presents equal or parallel alleys.

Or, the Quincunx is the figure of a plantation of trees disposed in several rows, both length and breadth.

Q U I

breadthwise, in such manner, that the first tree of the second row commences in the centre of the square formed by the two first trees of the first row, and the two first of the third, resembling the figure of the five at cards. This regular disposition of trees was formerly more regarded than at present, and is still much in practice in France for planting trees to form a grove.

Q U I

Trees planted in Quincunx are such as are planted in the following form :

QUINQUEFOLIUM. See POTENTILLA.

R.

R A I

RACEMIFEROUS signifies bearing in clusters.

RACEMUS, a cluster, is a stalk divided or branched into several foot-stalks, sustaining the flowers or fruit set together, as are the bunches of Grapes, Currants, &c. The first of these conditions distinguishes it from a spike, the last from a panicle.

RADIATED FLOWERS are such as have several semiflorets set round a disk in form of a radiant star, as are the flowers of Daisy, Cammomile, &c. These are called radiated discous flowers; those which have no such ray, are called naked discous flowers, as the Wormwood, Mugwort, Tansey, &c.

RADICLE denotes that part of the seed of a plant, which, upon its vegetation, becomes a little root, by which the tender plant at first receives its nourishment before the after-root be formed. This is that part of the seed, which, in making malt, shoots forth, and is called the come or comb.

RADISH. See RAPHANUS.

RADISH (HORSE.) See COCHLEARIA.

RAIN is generally accounted to be a crude vapour of the earth, but more especially of the sea, drawn up from thence by the attractive power of the sun, or carried thitherward by pulsion, and waisted by the winds into the aerial region, by which sublimation and rarefaction, and the virtual qualities of the sun and air, it is formed into clouds.

The crudities are dispelled, and these clouds suspend and hang in the air, and though it may be thought impossible that they should be so suspended in the air by reason of their great weight and pressure, yet it will not appear so on consideration.

When these vapours are thus drawn up to any considerable height by the strength of the air which is underneath them, and which still grows greater and greater, and by its motion, undulating this way and that way, they rise gradually through the air.

This is demonstrable by paper kites, which, after they are raised to about sixty feet high, rise easier and with greater swiftness, and the higher, still the better and stronger they fly.

These vapours, being thus arrived into the upper regions of the air, are soon aggregated and condensed into bodies and clouds.

And though they are blown here and there, they are still suspended, till they are released from their imprisonment by the genial disposition of the sun, or by the natural warmth, humidity and rarefaction of the air.

It is not to be doubted, but that the Rain drops out

R A I

of the clouds, because we do not find it rain, but where clouds are to be seen, and by how much the fairer the weather is, the seldomer it rains.

Rain is a very frequent and useful meteor, descending from above in form of drops of water.

Rain seems to differ from dew only in this, that dew falls at some particular times, and in very small drops, so as to be seen when it is down, but is scarce perceivable while it is falling; whereas Rain is grosser, and falls at any time.

Rain is apparently a precipitated cloud, as clouds are nothing but vapours raised from moisture, waters, &c. and vapours are demonstratively nothing else but little bubbles, or vesiculæ detached from the waters by the power of the solar or subterraneous heat, or both.

These vesiculæ, being specifically lighter than the atmosphere, are buoyed up thereby till they arrive at a region where the air is a just balance with them; and here they float, till by some new agent they are converted into clouds, and thence into either Rain, snow, hail, mist, or the like.

But the agent in this formation of clouds, &c. is a little controverted: the generality will have it the cold, which, constantly occupying the superior regions of the air, chills and condenses the vesiculæ at their arrival from a warmer quarter, congregates them together, and occasions several of them to coalesce into little masses; by this means their quantity of matter increasing in a greater proportion than their surface, they become an overload to the lighter air, and descend into Rain.

The coldness of the air may cause the particles of the clouds to lose their motions, and become less able to resist the gravity of the incumbent air, and consequently to yield to its pressure, and fall to the ground.

The wind may collect the vapours in such abundance, as first to form very thick clouds, and then to squeeze those clouds together, till the watery particles make drops too big to hang in the air.

But the grand cause, according to Mons. Rohault, is still behind; he conceives it to be the heat of the air, which, after continuing for some time near the earth, is at length carried up on high by a wind, and, there thawing the frozen villi or flocks of the half-frozen vesiculæ, reduces them into drops, which, coalescing, descend, and have their dissolution perfected in their progress through the lower and warmer stages of the atmosphere.

Monsieur Le Clerc and others ascribe this descent of the clouds rather to an alteration of the atmosphere than of the vesiculæ, and suppose it to proceed from

R A I

from a diminution of the spring, or elastic force of the air.

This elasticity, which depends chiefly or wholly upon the dry terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall upon the common principle of precipitation.

Now the little vesiculæ, by any or all of these means being once upon the descent, will persist therein, notwithstanding the increase of resistance they every moment meet withal in their progress through still denser and denser parts of the atmosphere:

For as they all tend towards the same point, viz. the center of the earth; the farther they fall, the more coalitions will they make; and the more coalitions, the more matter there will be under the same surface, the surface not only increasing as the squares, but the solidity as the cubes; and the more matter under the same surface, the less friction or resistance there will be to the same matter.

Thus, if the cold, the wind, &c. happen to act early enough to precipitate the vesiculæ, ere they are arrived to any considerable height, the coalitions being few in so short a descent, the drops will be proportionably small, and thus is formed what we call dew.

If the vapours prove more copious, and rise a little higher, we have a mist or fog.

A little higher still, and they produce a small Rain.

If they neither meet with cold or wind enough to condense or dissipate them, they form a heavy, thick, dark sky, which lasts sometimes several days or weeks.

Hence we may account for many of the phenomena of the weather, e. g. Why a cold is always a wet summer, and a warm a dry one, because the principle of precipitation is had in the one case, and wanting in the other:

Why we have ordinarily most Rain about the equinoxes, because the vapours arise more plentifully than ordinary in the spring, as the earth becomes loosened from the brumal constipations, and because, as the sun recedes from us in autumn, the cold increasing, the vapours that had lingered above, during the summer heats, are now dispatched down.

Why a settled, thick, close sky seldom ever rains, till it has been first cleared, because the equally confused vapours must first be condensed and congregated into separate clouds to lay the foundation of Rain, by which means the rest of the face of the heaven is left open, and pervious to the rays of the sun, &c.

Monsi. Le Clerc observes, that all winds do not produce Rains, but only such as collect a great quantity of vapours. Thus in Holland west winds are rainy, because they come from the ocean, and blow up the vapours; east winds blow clear, because they come over vast tracts of land; north winds are rainy, because they come from the north sea, but not so rainy as the west, because the cold north doth not yield such a quantity of vapours as the kinder climate of the Britannie ocean; south winds bring Rain too, for that they, consisting of vapours raised by the heat of the sun in a hot quarter, and so being elevated above others in the air, seem to lie upon our clouds, and press them down towards the earth.

Again: Rain may be produced after this manner. If the vapours rise in so great abundance as to reach and

R A I

minge with the clouds above them, then they cause Rain in very large drops, and this may happen in still sultry weather; for then the clouds, which are over our heads, have no sensible motion, and in the mean time the heat fills the air with vapours, which, joining with the clouds, and so being stopped in their progress, open a passage for the stores in the clouds to descend upon the earth.

Sometimes also the warm wind thaws the clouds into drops, as we see snow dissolved by heat; now by how much the thicker and sooner any such cloud was gathered, the larger are the drops that come from it, because a greater store of vapours was condensed there. From thence it is, that in summer time we have sudden showers of Rain in very large drops.

It ought also to be remembered, that in those countries which lie between the tropics, where they have the sun vertical, the Rain pours down for several weeks together more like pailfuls than drops. And it is very probable that this is the cause; viz. because at that time the sun draws up abundance of vapours, and rarefies them extremely, so that they are elevated as high as possible, and then are precipitated at once, being too copious and heavy to hang in the air; and besides, there may sometimes be a concurrence of neighbouring vapours, which will be ready to crowd into that part of the air, which is most rarefied by the heat of the sun meeting with the vapours, which are raised in that place, and produce very great clouds and Rain.

If any ask, How the drops of falling water come to be round, as in Rain? it is answered, That this does not happen by any disposition peculiar to the water, but because the drops are equally pressed by the air on every side, and thereby forced into a round figure, the resistance of the air being equal every way; but others give other reasons for it.

In Rain there are two distinct properties or species; the one which serves for the dissolution of the salts of the earth, and the other is a terrestrial matter, which it meets with in its sublimation, which may with some propriety be called either salt or nitre, and both these are useful in the business of vegetation.

Rain is operative in dissolving the salts that are in the earth, and cools and bathes the cortex or skin of all vegetables, and, by a sort of relaxation, causes the sap to pass up more freely, and by that means to grow, and shoot the better.

These foggy humid vapours arising out of the ground, &c. of which Rain is formed, would inevitably stagnate and poison the whole face of the earth, were they not sublimated by the air, and drawn up by the assistance of the sun into the upper regions, but, being there rarefied, they are made of second use in vegetation.

As to the quantity of Rain that falls, its proportion in several places at the same time, and in the same place at several times, we have store of observations, journals, &c. in the Memoires of the French Academy, the Philosophical Transactions, &c. an idea of which take as follows:

Upon measuring then, the Rain falling yearly, its depth, at a medium, is found as in the following table:

Proportion

Proportion of RAIN falling yearly, and its proportion in several places.													
At Townly in Lancashire, observed by Mr. Townly													
								42 $\frac{1}{2}$	Inches				
Upminster in Essex, by Mr. Derham

The Reverend Dr. Hales, in his excellent Treatise of Vegetable Staticks, tells us, that the quantity of Rain and dew that falls in a year is, at a medium, 22 inches, and that the quantity of the earth's evaporation in a year is at least $9 + \frac{1}{2}$ inches, since that is the rate at which it evaporates in a summer's day, from which $9 + \frac{1}{2}$ Inches is to be deducted 3. 39 inches, for circulating daily dew, there remains 6. 2 inches, which 6. 2 inches deducted from the quantity of Rain which falls in a year, there remains at least 16 inches depth to replenish the earth with moisture for vegetation, and to supply springs and rivers.

Hence we find, that 22 inches depth of Rain in a year is sufficient for all the purposes of nature in such flat countries as is that about Teddington near Hampton-Court; but in the hill countries, as in Lancashire, there falls 42 inches depth of Rain water, from which deducting seven inches for evaporation, there remains 35 inches depth of water, besides great supplies from much more plentiful dews than fall in plain countries.

Which vast stores seem so abundantly sufficient to answer the great quantity of water which is conveyed away by springs and rivers from those hills, that we need not have recourse for supplies to the great abyss, whose surface at high water is surmounted some hundreds of feet by ordinary hills, and some thousands of feet by those vast hills, from whence the longest and greatest rivers take their rise.

RAINBOW, a meteor in form of a particoloured arch or semicircle, exhibited in a rainy sky opposite the sun, by the rarefaction of his rays in the drops of falling rain.

The Rainbow, Sir Isaac Newton observes, never appears but where it rains in the sunshine, and may be represented artificially by contriving water to fall in little drops like rain, through which the sun shining exhibits a bow to the spectator's eye placed between the sun and the drops, especially if a dark body, e. g. a black cloth be disposed beyond the drops.

Anton. de Dominis first accounted for the Rainbow in 1611, he explained at large how it was formed by refraction and reflexion of the sun-beams in spherical drops of water, and confirmed his explication by experiments made with glass globes, &c. full of water, wherein he was followed by Des Cartes, who mended and improved upon his account.

But as they were both in the dark as to the true origin of colours, their explications are defective, and in some things erroneous, which, it is one of the glories of the Newtonian doctrine of colours, to supply and correct.

The following properties are ascribed to the Rainbow:

1. That it never appears but in a place opposite the sun; so that, when we look directly at it, the sun is always behind us.
2. That when the Rainbow appears, it always rains somewhere.
3. That the constant order of the colours is, that the outmost is red or Saffron colour; the next is yellow; the third is green; the fourth or inmost is Violet or blue; but these colours are not equally bright.
4. Two Rainbows appear together, one of which is higher and larger than the other, and shews the afore-said colours, but in an inverted order.
5. The Rainbow is always exactly round, but does not always appear equally entire, the upper or lower parts being very often wanting.
6. Its apparent breadth is always the same.
7. That those, who stand upon plain low ground, never see above half its circle, and oftentimes not so much.
8. The higher the sun is above the horizon, the less of the circle is seen, and, if there be no cloud to hinder, the lower, the more of it.
9. That never any Rainbow appears, when the sun is above 41 degrees 46 minutes high.

Lunar (Rainbow :) The moon also sometimes exhibits the phenomena of an iris or bow by the refraction of her rays in the drops of rain in the night time.

Aristotle

R A N

Aristotle says, he was the first that ever observed it; and adds, that it never happens, i. e. visible, but at the time of the full moon, her light at other times being too faint to reflect the light. After two refractions and one reflexion, the lunar iris has all the colours of the solar very distinct and pleasant, only faint, in comparison of the other, both from the different intensity of the rays, and the different disposition of the medium.

Marine (Rainbow) is a phænomenon sometimes observed in a much agitated sea, when the wind, sweeping part of the tops of the waves, carries them aloft, so that the sun's rays falling upon them, are refracted, &c. as in a common shower, and paint the colours of the bow.

F. Bourzes, in the Philosophical Transactions, observes that the colours of the Marine Rainbow are less lively, distinct, and of less duration, than those of the common bow; that there are scarce above two colours distinguishable, a dark yellow on the side next the sun, and a pale green on the opposite side. But these bows exceed as to number, there being sometimes twenty or thirty seen together; they appear at noon-day, and in a position opposite to that of the common bow, i. e. the concave side is turned upwards, as indeed it is necessary it should be, from what may be said in accounting for the appearance of the solar bow.

RAMUS, a branch, is the division of a stalk; in trees it is often called a bough.

RANDIA. Houft. Gen. Nov. 28. Lin. Gen. Plant. 194.

The CHARACTERS are,

The empalement of the flower is permanent, of one leaf, cut into five short segments at the brim. The flower is funnel-shaped, of one petal, cut into five parts at the top; it hath five short stamina terminated by oblong erect summits, and an oval germen supporting a cylindrical style, the length of the tube divided into two parts at the top, crowned by two obtuse unequal stigmas. The germen afterward becomes an oval capsule with one cell, having a hard cover, including many compressed cartilaginous seeds surrounded with pulp.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

We know but one SPECIES of this genus at present in the English gardens, viz.

RANDIA (*Mitis*) foliis ovatis emarginatis, spinis geminatis, caule fruticoso. *Randia* with oval leaves which are indented at the top, spines growing by pairs, and a shrubby stalk. *Randia frutescens*, spinis bijugis, foliis subrotundis floribus albis. Houft. MSS. *Shrubby Randia* with double spines, roundish leaves, and white flowers. Sir Hans Sloane titles it in the History of Jamaica, *Lycium forte*, foliis subrotundis integris, spinis & foliis ex adverso sitis. Vol. i. p. 40. *Boxthorn* with roundish entire leaves, which, as well as the spines, are placed by pairs.

This plant grows naturally at La Vera Cruz, where the late Dr. Houstoun found it in plenty, and sent the seeds to Europe; he gave this title to the genus in honour of Mr. Isaac Rand, who was a curious botanist. It was discovered by Sir Hans Sloane in the island of Barbadoes.

It rises with a shrubby stalk to the height of ten or twelve feet, covered with a whitish bark. The branches come out opposite from the side of the stalk, each pair crossing the other; the leaves are of a thick consistence, about an inch long, and three quarters broad, a little indented at the top, and are placed by pairs standing upon short foot stalks. At the joints immediately under the leaves are produced two short spines standing opposite. The flowers are produced from the side of the branches; they are small, white, tubulous, and divided at the brim slightly into five parts. These are succeeded by oval berries about the

R A N

size of a marble, having a brittle shell, under a thin skin, with one cell, inclosing many compressed seeds surrounded with a black pulp. It is propagated by seeds, which should be sown early in the spring in pots filled with light fresh earth, and plunged into a hot-bed of tanners bark, observing to water the earth frequently but gently, to promote the vegetation of the seeds. When the plants come up, they must have fresh air admitted to them every day when the weather is warm, and should be often refreshed with water. In about a month's time after the plants are up, they will be fit to transplant, when they should be carefully shaken out of the pots, and each planted into a separate small pot filled with light fresh earth, and then plunged into the hot-bed again, where they must be screened from the sun until they have taken new root; after which time, they must have air and moisture in proportion to the warmth of the season. The plants may remain in the hot-bed till toward Michaelmas, when the nights begin to be cold, at which time they should be removed into the stove, and if they are plunged into the bark-bed, it will greatly forward their growth, though they will live in the dry stove, if they are kept in a moderate temperature of heat. During the two first seasons, while the plants are young, it will be proper to keep them constantly in the stove, but their leaves must be washed whenever they contract filth; this will bring them forward; but, after the plants have obtained strength, they may be exposed every summer to the open air in the warmest part of the year for two or three months, provided they are placed in a warm situation, but in winter they must be constantly placed in a stove, and kept in a moderate warmth, otherwise they will not live in this country.

The leaves of this plant continue green throughout the year, which renders the plant valuable, because it makes an agreeable variety in the winter season, when mixed with other tender plants.

RANUNCULUS. Tourn. Inst. R. H. 285. tab. 149. Lin. Gen. Plant. 619. [so called, as some say, from Rana, Lat. a frog, on account of its delighting to grow in moist places, which frogs frequent.] Crow-foot.

The CHARACTERS are,

The empalement of the flower is composed of five oval concave leaves; the flower has five obtuse petals, which have a narrow base; each of these have an open nectarium upon their tails. It hath many stamina, about half the length of the petals, terminated by oblong, erect, twin summits, and numerous germen collected in a head having no styles, but are crowned by small reflexed stigmas. The germen afterward become seeds of uncertain irregular figures, fastened to the receptacle by very short foot-stalks.

This genus of plants is ranged in the seventh section of Linnæus's thirteenth class, which contains those plants whose flowers have many stamina and germen. I shall not here enumerate all the species of this genus, many of which are common weeds in most parts of England, and others are so in several parts of Europe, so are rarely admitted into gardens, therefore I shall only mention those sorts which are cultivated in gardens, or have double flowers.

The SPECIES are,

1. RANUNCULUS (*Acris*) calycibus patulis, pedunculis teretibus, foliis tripartito-multifidis, summis linearibus. Lin. Flor. Succ. 466. flore pleno. *Ranunculus* with a spreading empalement, a taper foot-stalk, many-pointed leaves divided by threes, and those at the top linear and bearing a double flower. *Ranunculus hortenensis* erectus, flore pleno. C. B. P. 179. *Upright Garden Ranunculus* with a double flower.
2. RANUNCULUS (*Repens*) calycibus patulis, pedunculis sulcatis, repentibus, foliis compositis. Flor. Succ. 468. flore pleno. *Ranunculus* with a spreading empalement, furrowed foot-stalks, creeping shoots, and compound leaves with a double flower. *Ranunculus hortenensis* inclinans. C. B. P. 179. *Inclining Garden Ranunculus*.

3. **RANUNCULUS** (*Creticus*) foliis radicalibus reniformibus crenatis sublobatis, caulinis tripartitis lanceolatis integerrimis, caule multifloro. Lin. Sp. Plant. 550. *Ranunculus with kidney-shaped lower leaves, which are crenated and almost divided into lobes, but those upon the stalks divided into three spear-shaped lobes which are entire, bearing many flowers on a stalk.* *Ranunculus asphodeli radice Creticus.* C. B. P. 181. *Asphodel-rooted Ranunculus of Crete.*
4. **RANUNCULUS** (*Aconitifolius*) foliis omnibus quinatis lanceolatis inciso-ferratis. Hort. Cliff. 229. flore pleno. *Ranunculus with all the leaves divided into five spear-shaped segments which are sawed, and bear a double flower.* *Ranunculus folio aconiti, flore albo multiplici.* C. B. P. 179. *Ranunculus with a Wolfsbane leaf and a double white flower, commonly called Mountain Ranunculus.*
5. **RANUNCULUS** (*Gramineus*) foliis lanceolato-linearibus sessilibus, caule erecto radice bulboso. Lin. Sp. Plant. 773. *Ranunculus with linear leaves sitting close to the stalk, which is erect, having very long foot-stalks to the flowers.* *Ranunculus montanus, folio gramineo.* C. B. P. 181. *Mountain Ranunculus with a Grass leaf.*
6. **RANUNCULUS** (*Rutæfolius*) foliis supra decompositis, caule simplicissimo unifolio, radice tuberosa. Hort. Cliff. 230. flore pleno. *Ranunculus with leaves which are decomposed above, a single stalk bearing one leaf, and a tuberous root with a double flower.* *Ranunculus rutaceo folio, flore pleno, luteo, minori.* Flor. Bat. 2, 3. *Rue-leaved Ranunculus with a smaller double yellow flower.*
7. **RANUNCULUS** (*Auricomus*) foliis radicalibus reniformibus crenatis incis, caulinis digitatis linearibus, caule multifloro. Hort. Cliff. 229. flore pleno. *Ranunculus with kidney-shaped, crenated, lower leaves, those on the stalks hand-shaped and linear, and stalks bearing many flowers.* *Ranunculus dulcis multiflorus.* Tab. Icon. 53. *Sweet-smelling Ranunculus bearing many flowers.*
8. **RANUNCULUS** (*Amplexicaulis*) foliis ovatis acuminatis amplexicaulibus, caule radice fasciculata. Hort. Cliff. 229. *Ranunculus with oval, acute-pointed leaves which embrace the stalks, many flowers upon a stalk, and roots growing in bunches.* *Ranunculus montanus, folio plantaginis.* C. B. P. 180. *Mountain Ranunculus with a Plantain leaf.*
9. **RANUNCULUS** (*Grandiflorus*) caule erecto bifolio, foliis multifidis, caulinis alternis sessilibus. Flor. Leyd. Prod. 492. *Ranunculus with an erect stalk, having two leaves which are many-pointed, and those upon the stalks alternate sitting close.* *Ranunculus Orientalis, aconiti folio, flore maximo.* Tourn. Cor. 22. *Eastern Ranunculus with a Wolfsbane leaf and a large flower.*
10. **RANUNCULUS** (*Sanguineus*) foliis ternatis biternatifque, foliolis trifidis obtusis, caule simplici. *Ranunculus with leaves placed by threes, which are divided again into twice trifoliate leaves, ending in three obtuse points, with a simple stalk.* *Ranunculus asphodeli radice, flore sanguineo.* C. B. P. 281. *Asphodel-rooted Ranunculus with a bloody flower.*
11. **RANUNCULUS** (*Asiaticus*) foliis ternatis biternatifque, foliolis trifidis incis, caule infernè ramoso. Lin. Sp. 552. *Ranunculus with trifoliate and twice trifoliate leaves, whose lobes are trifid, cut, and a stalk branching at the bottom.* *Persian Ranunculus.*

The first sort is a variety of the common upright Meadow Ranunculus, which grows naturally in every pasture; but as this hath double flowers, so it is cultivated in gardens. The stalks of this are erect, and rise more than a foot high; the lower leaves have very long foot-stalks; they are divided into several segments, resembling those of the Aconite, or Monk's-hood; the leaves toward the top of the stalk are cut into linear segments to the bottom; the stalk branches at the top into several foot-stalks, which are terminated by double yellow flowers. These appear in May, and if they stand in a shady situation, will continue a month in flower; and many times in moist seasons, there are small flowers rising out of the middle of the others. This is propagated by parting of the roots in autumn,

and should be planted in a moist soil and a shady situation.

The second sort is a variety of the common creeping Crow-foot, which grows naturally in cultivated fields in most parts of England. The shoots from the root of this sort trail upon the ground, and put out roots from every joint in the manner of the Strawberry, so that when it is once introduced into a garden, it will multiply fast enough; the leaves and stalks are hairy, the flowers are yellow and double, but small. It flowers the latter end of May.

The third sort grows naturally in Crete; this hath an Asphodel root; the lower leaves are large, kidney-shaped, and a little hairy, about three inches long and four broad; they are deeply crenated on their borders, and are divided almost into five lobes, and have long foot-stalks which are hairy. The stalks rise about nine or ten inches high, and are garnished with two or three leaves, which are cut into three segments, and are entire; the top of the stalk divides into several foot-stalks, each sustaining one large, pale, yellow flower. This sort flowers the beginning of June. It is propagated by offsets from the roots, in the same way as the Garden Ranunculus, and should be planted in a warm border, otherwise the frost will destroy the roots.

The fourth sort grows naturally upon the Alps, with a single flower, but the double has been obtained by seeds, and is preserved in many curious gardens for the beauty of its flowers. This is by some gardeners called the Fair Maid of France; it hath a perennial root, composed of many strong fibres; the leaves are divided into five spear-shaped lobes; the four side lobes are upon foot-stalks coming from the side of the principal stalk, and the middle one terminates it; they are deeply sawed on their edges, and have several longitudinal veins. The stalks rise a foot and a half high, and branch out at the top into three or four divisions, at each of which there is one leaf, of the same shape with the lower, but smaller. The flowers are pure white, and very double, each standing upon a short foot-stalk. It flowers in May. This is propagated by parting the roots in autumn, as soon as the leaves decay, and should be planted in an east border and a loamy soil, not too stiff.

The fifth sort grows naturally on the Alps; this has a perennial root; the leaves are long and narrow like those of Grass, sitting close to the stalks, which rise a little more than a foot high, dividing at the top into three or four slender foot-stalks, which are terminated by single yellow flowers like those of the common Butterflower. This flowers the beginning of May. There is a double flower of this kind in the Paris Garden, but we have not yet got it in England.

The sixth sort grows naturally in Austria, and also in the Levant. This hath a tuberous root, the leaves decomposed and smooth; the stalks rise near a foot high, and have one leaf of the same shape with the lower, but smaller; the stalk is terminated by one double flower, about the size of the common Butterflower, but of a fine bright yellow colour. This flowers in the end of May. It is propagated by offsets from the roots in the same way as the Garden Ranunculus, and must be planted in a warm border, otherwise the frost will destroy the roots in winter.

The seventh sort is a variety of the common sweet Wood Ranunculus, which hath a double flower. This is a very hardy plant; it may be easily propagated by the root, and should have a loamy soil and a shady situation.

The eighth sort grows naturally upon the Alps and Apennine Mountains, where it seldom rises more than six inches high; the leaves are narrow, and but one flower upon a stalk; but when it is planted in a garden, the stalks rise a foot and a half high, and are garnished with oval acute-pointed leaves, three inches long, and one inch and a half broad, smooth, of a grayish colour, embracing the stalks with their base; this branches out at the top into several foot-stalks, each sustaining one white flower. This flowers in the middle

R A N

middle of April, and continues near a month in beauty, if planted in a shady place. It is propagated by parting of the roots in autumn, soon after the leaves decay, and may be planted on a shady border, where it will thrive exceedingly.

The ninth sort was discovered by Dr. Tournefort in the Levant; this hath a perennial root, from which arise several leaves, cut into many points like those of Wolfbane; the stalk rises a foot high, and is garnished with two leaves which sit close together, and are alternate. This is terminated by one single yellow flower, much larger than that of the Butterflower, and blows in May. It is propagated by parting the roots in autumn, and should be planted in a light loamy soil.

The tenth sort is common in the English gardens, and was some years past more so than at present; for since the Persian *Ranunculus* has been introduced here, and so many fine varieties have been obtained from seeds, they have almost banished this sort out of the gardens. It hath a grumous root like the Persian sort; the leaves are divided by threes, and those are twice again divided by threes, and are obtuse-pointed; the stalk rises about nine inches high, terminated by one large double red flower. This appears the latter end of April, and have sometimes one or two very small flowers branching out from the side.

The eleventh sort was originally brought from Persia, but since it has been in Europe, has been greatly improved by culture, and many new flowers obtained from seeds, amongst which are many with semidouble flowers, which produce seeds; and from these there are such prodigious varieties of new flowers annually obtained, which are so large, and of such variety of beautiful colours, as to exceed all other flowers of that season, and even vie with the most beautiful Carnations; these are many of them finely scented, and the roots, when strong, generally produce twenty or thirty flowers upon each; which, succeeding each other, continue in beauty a full month or longer, according to the heat of the season, or the care taken to defend them from the injuries of the weather; all which excellent qualities have rendered them so valuable, that the old sorts are almost disregarded except in some old gardens.

All the very double flowers never produce seeds, so that they are only multiplied by offsets from their roots, which they generally produce in great plenty, if planted on a good soil, and duly attended in winter. The season for planting their roots is any time in October, for if they are planted sooner, they are apt to come up in a short time, and grow pretty rank before winter, whereby they will be in greater danger of suffering by frost; and if they are planted much later, they will be in danger of perishing under ground; so that you should not keep them out of the ground any longer than the beginning or middle of October. The beds in which the Persian *Ranunculus* roots are planted, should be made with fresh, light, sandy earth, at least three feet deep: the best soil for them may be composed in this manner, viz. Take a quantity of fresh earth from a rich upland pasture, about six inches deep, together with the green sward; this should be laid in a heap to rot for twelve months before it is mixed, observing to turn it over very often, to sweeten it and break the clods; to this you should add a fourth part of very rotten neats dung, and a proportionable quantity of sea or drift-sand, according as the earth is lighter or stiffer; if it be light and inclining to a sand, there should be no sand added; but if it be a hazel loam, one load of sand will be sufficient for eight loads of earth; but if the earth is strong and heavy, the sand should be added in a greater proportion; this should be mixed eight months or a year before it is used, and should be often turned over, in order to unite their parts well together before it is put into the beds.

The depth which this should be laid in the beds, must be about three feet, and should be below the surface, in proportion to the dryness or moisture of the place

R A N

where the beds are situated; for in dry ground it should be two feet eight inches below the surface, and the beds raised four inches above; but in a moist place they should be two feet below, and one foot above the ground; and in this case, it will be very proper to lay some rubbish and stones in the bottom of each bed, to drain off the moisture; and if upon this, at the bottom of the beds, some very rotten neats dung is laid two or three inches thick, the roots will reach this in the spring, and the flowers will be the fairer. This earth I would by no means advise to be screened very fine, only in turning it over each time, you should be careful to break the clods, and throw out all large stones, which will be sufficient; for if it is made very fine, when the great rains in winter come on, it will cause the earth to bind into one solid lump, whereby the moisture will be detained, and the roots, not being able to extend their tender fibres, will rot. Of this I have had many examples, but one particularly to my cost: when I had procured a fine parcel of these roots from abroad, and being desirous of having them thrive very well, I took great pains to screen the earth of my beds very fine, which I had laid above two feet deep, and planted a good part of my roots therein; but the season advancing, and having a great deal of other business upon my hands, I did not screen the earth of all my beds, but planted some of them without doing any thing more than raking them; and the success was, that the roots in those beds which were screened did, great part of them, entirely rot; and the remaining part were so weak, as not to produce any good flowers, whereas those which were planted in the beds which were not screened, did thrive and flower very well, and scarce any of the roots failed, though the earth of all the beds was the same, and were in the same situation, both with regard to wind and sun; so that the damage which those roots sustained, was owing entirely to the fineness of the earth; and this I have several times since observed in other gardens.

I am aware that this depth of three feet, which I have here directed to make the beds of these flowers, will be objected to by many persons, on account of the expence and trouble of preparing them, as also supposing it necessary to make the beds so deep, for flowers whose roots are small; but if they will give themselves the trouble of making the experiment, by preparing one bed in this manner, and another in the common way, and plant them both with the same flowers, they will soon be convinced of their error, by the success of the flowers. For in the beds which have been prepared of this depth, I have seen one root produce upward of fifty flowers, each of which grew near a foot high, and were extremely large and fair; whereas in the common method of culture, they are thought to do very well when they produce eight or ten flowers on each root, and these grow six inches high; but if a person will trace the length of the small fibres of these roots, he will find them extend three or four feet downwards. And as it is by these distant fibres that the nourishment is taken in, for the increase and strength of the flowers; so if these meet with a poor barren soil below, they shrink, and the flowers are starved for want of proper nourishment in the spring, when it is most required.

The beds being thus prepared, should lie a fortnight to settle before the roots are planted, that there may be no danger of the earth settling unequally after they are planted; which would prejudice the roots, by having hollow places in some parts of the bed, to which the water would run and lodge, and so rot the roots there. Then having levelled the earth, laying the surface a little rounding, the beds should be marked out in rows by a line, at about six inches distance each way, so that the roots may be planted every way in straight lines; then you should open the earth with your fingers at each cross, where the roots are to be planted, at about two inches deep, placing the roots exactly in the middle, with their crowns upright; then with the head of a rake you should draw the earth up-
on

on the surface of the bed level, whereby the top of the roots will be covered with earth near two inches, which will be sufficient. This work should be done in dry weather, because the earth will then work better than if it were wet; but the sooner after planting there happens to be rain, the better it will be for the roots; for if it should prove dry weather long after, and the earth of the beds be very dry, the roots will be subject to mould and decay; therefore in such a case it will be proper to give a little water to the beds, if there should no rain happen in a fortnight's time, which indeed is very rare at that season of the year, so that they will seldom be in danger of suffering that way. When the roots are thus planted, there will no more be required until toward the end of November; by which time they will begin to heave the ground, and the buds of their leaves appear; when you should lay a little of the fresh earth, of which the beds were composed, about half an inch thick over the beds, which will greatly defend the crown of the root from frost; and when you perceive the buds to break through this second covering, if it should prove very hard frost, it will be very proper to arch the beds over with hoops, and cover them with mats, but especially in the spring, when the flower-buds will begin to appear; for if they are exposed to too much frost, or blighting winds at that season, their flowers seldom open fairly, and many times their roots are destroyed.

In the beginning of March the flower-stems will begin to rise, at which time you should carefully clear the beds from weeds, and stir the earth with your fingers between the roots, being very careful not to injure them; this will not only make the beds appear handsome, but also greatly strengthen their flowers in blowing; and if the nights prove frosty, the beds should be covered with mats every evening, and shaded from the sun in the heat of the day. When the flowers are past and the leaves are withered, you should take up the roots, and carefully clear them from the earth; then spread them upon a mat to dry, in a shady place; after which they may be put up in bags or boxes in a dry room, until the October following, which is the season for planting them again.

These Persian sorts are not only propagated by offsets from the old roots, but are also multiplied by seeds, which the semi-double kinds produce in plenty; therefore, whoever is desirous to have these in perfection, should annually sow their seeds, from which new varieties will be every year produced; but in order thereto, you should be careful in saving your seed, or in procuring it from such persons as understand how to save it; that is, who will be careful not to leave any flowers for seeds, but such as have five or six rows of petals at least, and are well coloured; for since these flowers increase plentifully, it is not worth the trouble to sow any indifferent seeds, because there can be but little hopes of obtaining any good flowers from them.

Being prepared with seeds, about the middle of August, which is the proper season for sowing them, you should get some large pots, flat seed-pans, or boxes. These should be filled with light rich earth, levelling the surface very even; then sow the seeds thereon pretty thick, and cover it about a quarter of an inch thick with the same light earth; after which, you should remove these pots, pans, or boxes, into a shady situation, where they may have the morning sun until ten of the clock; and if the season prove dry, you must often refresh them gently with water, being very careful in doing of this, not to wash the seeds out of the ground. In this situation the pots should remain until the beginning of October, by which time the plants will sometimes begin to come up, (though often the seeds will remain in the earth until the end of November, before the plants appear;) but then you should remove the pots into a more open exposure, where they may have the full sun, which at that time is necessary to exhale the moisture of the earth; but toward the middle of November, when you are apprehensive of frost, the pots

should be removed under a common hot-bed frame, where they may be covered with the glasses in the night time, and also in bad weather; but in the day, when the weather is mild, they should be entirely opened, otherwise the plants will draw up too weak. The only danger they are in, is violent rains and frosts; the first often rotting the tender plants, and the frost will often turn them out of the ground, therefore they should be carefully guarded against both these.

In the spring, as the season grows warm, these pots should be exposed to the open air, placing them at first near the shelter of a hedge, to protect them from the cold winds; but toward the beginning or middle of April, they should be removed again into a more shady situation, according to the warmth of the season; and if it should prove dry, they must be sometimes refreshed with water; but you should be careful not to give it them in great quantities, which is very apt to rot these tender roots; and in the latter end of April or beginning of May, they should be placed where they may have only the morning sun; in which place they may remain till their leaves decay, when they may be taken out of the earth, and the roots dried in a shady place; after which they may be put up in bags, and preserved in a dry place till the October following, when they must be planted in the manner before directed for the old roots.

The spring following these roots will flower, at which time you should carefully mark such of them as are worthy to be preserved, and the single, or bad coloured flowers may be pulled and thrown away, which is the surest method of removing them from the good sorts; for if they are permitted to remain together until their leaves decay, there may be some offsets of the bad sorts mixed with the good flowers. You should not suffer those flowers, which you intend to blow fine the succeeding year, to bear seeds, if they are inclinable so to do, but cut off the flowers when they begin to decay; for those roots which have produced seeds, seldom flower well afterwards; nor will the principal old root, which has flowered strong one year, ever blow so fair as will the offsets, which is what should be principally observed, when a person purchases any of these roots; for a great part of the complaints made by those who have bought these roots at a dear rate, is principally owing to this. For the persons who sold them, being apprised of this matter, have parted with their old roots to their purchasers, and reserved the offsets for their own use; which old roots have so much degenerated from what they were the preceding year, as to cause a suspicion, whether the persons they were purchased from had not changed the roots: and this degeneracy always attends these flowers, after having flowered extremely large and fair, or that they have been permitted to seed; so that it is absolutely necessary to sow seeds every year, in order to preserve a succession of good flowers.

The manner of preparing the beds, and the distance and method of planting the roots, having been already directed, I shall not repeat it here, but only observe, that these flowers being tender, must be protected from hard frosts, and cutting sharp winds, especially after Christmas, when their flower-buds are forming; for if they are neglected at that season, their flowers will rarely prove fair; nor should you suffer them to receive too much wet in winter or spring, which is equally as injurious to them as frost. In planting these roots you should observe to place the semi-double kinds, from which you intend to save seeds, in separate beds by themselves, and not intermix them with the double flowers, because they will require to be treated in a different manner; for when the flowers of the semi-double kinds begin to fade, you should carefully guard them from too much wet; for if they are permitted to receive hard rains, or are watered at that season, the seeds rarely come to maturity, or they are so weak, that scarce one in fifty of them will grow.

When

When the seed begins to ripen (which may be easily known by separating from the axis and falling) you should look it over every day, gathering it as it ripens; for there will be a considerable distance in the seeds of the same bed coming to maturity, at least a fortnight, and sometimes three weeks or a month. When you gather the seed, it should not be exposed to the sun, but spread to dry in a shady place; after which, you must put it up where the vermin cannot come to it, until the time of sowing it.

By this method of sowing seeds every year, you will not only increase your stock of roots, but also raise new varieties, which may be greatly mended by changing the seeds into fresh ground; for if a person continually sows his seed in the same garden many years, they will not produce near so fine flowers as if he procured his seeds at some distance, which is also the case with most other plants.

It will also be necessary to take away all the earth out of the beds in which the roots were blown the preceding year, and put in new, if you intend to plant Ranunculuses there again; otherwise they will not thrive near so well, notwithstanding you may add some new compost to the beds, and this is what all the curious florists continually observe.

R A P A. Tourn. Inst. R. H. 228. tab. 112. Brassica. Lin. Gen. Plant. 734. Turnep; in French, *Navet*.

The CHARACTERS are,

The empalement of the flower is three-leaved, coloured, and erect. The flower hath four plain spreading petals, which are narrow at their base and entire. It has four oval honey glands, situated between the stamina and style, and six erect awl-shaped stamina; the two which are opposite are the length of the empalement, the other four are longer, terminated by erect acute-pointed summits. It hath a taper germen, supporting a short thick style, crowned by an entire headed stigma. The germen afterward becomes a long taper pod depressed on the sides, opening in two cells, which are filled with roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, which includes those plants whose flowers have two short and four longer stamina, and the seeds are in oblong pods; and he joins this genus to the Brassica, which, in a system of botany may be allowable, though not in a treatise of gardening.

The SPECIES are,

1. RAPA (*Rotunda*) radice caulescente orbiculata depressâ carnosâ. Turnep with an orbicular, depressed, fleshy root. Rapa sativa rotunda radice candidâ. C. B. P. 89. Garden Turnep with a white root.
2. RAPA (*Oblonga*) radice oblongâ carnosâ. Turnep with an oblong fleshy root. Rapa sativa, oblonga, seu fœmina. C. B. P. 90. Turnep with an oblong root, or female Turnep.
3. RAPA (*Napus*) radice caulescente fusiformi. Turnep with a spindle-shaped root. Napus sativa, radice albâ. C. B. P. 95. Garden Naphew with a white root, commonly called French Turnep.

The first is the Turnep which is commonly cultivated in the fields, of which there are the following varieties, viz. The round, red, or purple-topped Turnep, the green-topped Turnep, the yellow Turnep, the black-rooted Turnep, and the early Dutch Turnep. The last sort is commonly sown early in the spring, to supply the markets in May and June, but is never cultivated for a general crop. The red-rooted Turnep was formerly more cultivated in England than at present; for since the large green-topped Turnep has been introduced, all the skilful farmers prefer it to the other sorts; the root of this will grow to a large size, and continue good much longer than the other sorts. The next to this is the red or purple-topped Turnep, which will also grow large, and are extremely good for some time; but the roots of this will become stringy much sooner than those of the green-topped. The long-rooted Turnep, the yellow Turnep, and the blackish-rooted Turnep, are now rarely cultivated in England, neither of them being so good for the table or for feed as the red, and par-

ticularly the green-topped Turnep, though there are some few persons who sow them for the sake of variety. The early Dutch Turnep is chiefly sown in the spring, to supply the table before any of the sorts can be procured; and when they are drawn off young, are tolerably good; but if they are left to grow large, they are stringy and very rank, so are unfit for use.

The French Turnep is not much cultivated in England, but in France and Holland they are in great esteem, especially for soups; their roots being small, are boiled whole in the soup, and so served up to the table; these must also be used while they are young, otherwise they will become rank and stringy.

These are by some supposed to be only varieties which have been accidentally obtained from seeds, therefore I have not enumerated them as distinct species; but yet I am certain they are constant where care is taken in the saving of their seeds, not to suffer any mixture of plants to stand for seeds: I have sown of three or four sorts several years, and have always found them retain their differences; however, it is not easy to determine, if some of these were not by culture first obtained from the seeds of the common white Turnep. The yellow Turnep seems most unlikely to have been an accidental variety, for I have never known this alter, and the roots are yellow within, whereas all the other have white flesh, notwithstanding their outsides are of very different colours.

The long-rooted Turnep is, I think, a distinct species, the form of the root, and its manner of growth being totally different from the other sorts. I have seen these roots as long as those of some Parsneps, and nearly of the same shape; these run deep into the ground, so are unfit for feeding cattle; and unless they are used very young, become strong, so not proper for the table, which has occasioned their being rejected of late years.

The green-topped Turnep grows above the ground more than any of the other, which renders it preferable for feeding cattle, and being the softest and sweetest root when grown large of any of the kinds, is most esteemed for the table; but in very severe winters, they are in greater danger of suffering by frost, than those whose roots lie more in the ground, especially if they are not covered by snow; for when they are frequently hard frozen and thawed, it causes them to rot sooner than those whose flesh is less tender and sweet. I have seen the roots of this sort, which were more than a foot diameter boiled, and were as sweet and tender as many of the smallest roots.

Turneps delight in a light, sandy, loamy soil, which must not be rich, for in a rich soil they grow rank and are sticky; but if it be moist, they will thrive the better in summer, especially in fresh land, where they are always sweeter than upon an old worn out, or a rich soil.

The common season for sowing of Turneps, is any time from the beginning of June till the middle of August, or a little later, though it is not advisable to sow them much after; because, if the autumn should not prove very mild, they will not have time to apple of a proper size before winter; nor will the roots of those which are sown after the end of July grow very large, unless the frost keeps off long in autumn. But, notwithstanding this is the general season in which the greatest part of Turneps are sown in the country, yet about London they are sown successively from March to August, by those who propagate them to supply the markets with their roots; but there is a great hazard of losing those which are sown early in the year, if the season should prove dry, by the fly, which will devour whole fields of this plant while young; so that where a small quantity for the supply of a family is wanted, it will be absolutely necessary to water them in dry weather; and where a person sows those seeds in April and May, it should always be upon a moist soil, otherwise they seldom come to good, the heat of the weather at that season being too great for them upon a dry soil; but those which

are intended for the general crop, are sown toward the latter end of June, when they commonly receive some refreshing showers to bring them forward; without which, it is very common to have them all destroyed.

These seeds should always be sown upon an open spot of ground; for if it is near hedges, walls, buildings, or trees, they will draw up, and be very long topped, but their roots will not grow to any size. They are sown in great plenty in the fields near London, not only for the use of the kitchen, but for cattle in winter, when there is a scarcity of other food; and by this way is become a great improvement to barren sandy lands, particularly in Norfolk, where, by the culture of Turneps only, many persons have doubled the yearly value of their ground.

The land upon which this seed is sown, should be ploughed in April, and twy-fallowed in May, that is, once more ploughed, and twice well harrowed, and made very fine; then the seed should be sown pretty thin (for it being small, a little will sow a large piece of ground; two pounds of this seed is full sufficient for an acre of any land, but one pound is the common allowance.) The seed must be harrowed in as soon as it is sown, with a short tined harrow, and the ground rolled with a wooden roll, to break the clods and make the surface even. In ten days or a fortnight after sowing, the plants will come up, at which time, if the season should prove dry, they will be in great danger of being destroyed by the fly, which is too often the case with this crop; but if it so happen, the ground must be sowed again; for the seed being cheap, the chief expence is the labour; but the ground should be first harrowed to loosen it, especially if it is stiff land; there have been many directions given for to prevent this destruction, but scarce one has succeeded on trial.

When the plants have got four or five leaves, they should be hoed to destroy the weeds, and to cut up the plants where they are too thick, leaving the remaining ones about six or eight inches asunder each way, which will be room enough for the plants to stand for the first hoeing; and the sooner this is performed, when the plants have four leaves, the better they will thrive; but in the second hoeing, which must be performed about a month after the first, they should be cut up, so that the remaining plants may stand fourteen or sixteen inches distance, or more, especially if they are designed for feeding of cattle; for where the plants are allowed a good distance, the roots will be proportionably large, provided the ground is good; so that what is lost in number, will be overgained by their bulk, which is what I have often observed. But in such places where they are sown for the use of the kitchen, they need not be left at a greater distance than a foot, because large roots are not so generally esteemed for the table.

It is not many years since the practice of sowing Turneps for feeding of cattle has been of general use; how it happened that this improvement should have been so long neglected in every part of Europe, is not easy to determine; since it is very plain, that this piece of husbandry was known to the ancients. For Columella, in treating of the several kinds of vegetables which are proper for the field, recommends the cultivating Rapa in plenty; because (says he) those roots which are not wanted for the table, will be eaten by the cattle. And yet this plant was not much cultivated in the fields till within a century past; nor is the true method of cultivating Turneps yet known, or at least not practised, in some of the distant counties of England at this time. For in many places the seed is sown with Barley in the spring, and those plants which come up, and live till the Barley is cut, produce a little green for the sheep to pick up, but never have any roots. In other places, where the Turnep-seed is sown by itself, the method of hoeing them is not understood, so that weeds and Turneps are permitted to grow together, and where the Turneps come up thick in patches, they are never thinned; so that they draw up to have

long leaves, but never can have good roots, which is the principal part of the plant, therefore should be chiefly attended to.

The general method now practised in England, for cultivating this plant in the fields, is the same as is practised by the farming gardeners, who supply the London markets with these roots, which is as before directed. But it is only within the compass of half a century, that the country people have been acquainted with the method of hoeing them; so that the farmers usually employed gardeners, who had been bred up in the kitchen-gardens, to perform this work. And the usual price given per acre, for twice hoeing and leaving the crop clean, and the plants set out properly, was seven shillings; at which price the gardeners could get so much per week, as to make it worth their while to leave their habitations, and practise this in different counties during the season for this work, which always happens after the greatest hurry of business in the kitchen-garden is over; so that they usually formed themselves in small gangs of six or seven persons, and set out on their different routs, each gang fixing at a distance from the rest, and undertaking the work of as many farmers in the neighbourhood as they could manage in the season; but as this work is now performed by many country labourers, that practice is lost to the kitchen-gardeners, the country labourers doing it much cheaper.

There has also been another method practised very lately, by some very curious farmers, in cultivating of Turneps; which is, by sowing the seed in rows with the drill plough. In some places the rows have been sown three feet asunder, in others four, in some five, and some six. The latter has been commended by skilful persons as the most proper distance; for although the intervals are so large, yet the crop produced on an acre has been much greater than upon the same quantity of land where the rows have been but half this distance; and upon all the fields which have been cultivated for Turneps, the crops have greatly exceeded those which have been hand-hoed. The late Lord Viscount Townshend was at the expence of making the trial of these two different methods of husbandry, with the greatest care, by equally dividing the same fields into different lands, which were alternately sown in drills, and the intermediate lands in broad-cast. The latter were hoed by hand, in the common method, and the other cultivated by the hoeing plough; and when the roots were fully grown, his Lordship had an equal quantity of land, which had been sown in different methods, measured, and the roots drawn up and weighed; and those roots which had been cultivated by the plough, were so much larger than the other, that the crop of one acre, weighed a ton and a half more than that of an acre in the other husbandry.

But when the Turneps are sown in drills, they will require to be hoed by hand, to separate and cut out the plants where they are too near together in the rows, as also to cut up the weeds between the plants, where the plough cannot reach them. If this is carefully performed, the ploughing of the intervals will encourage the growth of the roots, by thus stirring of the ground, and prepare it much better for the crop of Barley, or whatever else is sown the following spring. This method of culture may be supposed to be more expensive than that commonly practised, by those unacquainted with it; but those who have made trials of both, find the horse-hoeing to be much the cheapest, and by far the best. For the country people, who are employed in hand-hoeing of Turneps, are very apt to hurry over their work, so that half the weeds are left growing, and the plants are seldom singled out so well as they should be; nor are they curious enough to distinguish the Charlock (which is one of the most common weeds in arable land) from the Turneps; so that about the middle of September, it is very common to see the fields of Turneps full of the yellow flowers of the Charlock. Now, in the horse-

R A P

horse-hoing, all the weeds in the intervals will be entirely destroyed; so that if a few plants of Charlock in the rows of Turneps should be overlooked, they may be easily drawn out when they appear visible; and by this method, the land will be sooner and better cleaned from weeds.

The greatest evil which attends a crop of Turneps, is that of their being destroyed by the fly, which usually happens soon after the plants come above ground, or while they are in the seed leaf; for, after they have put out their rough leaves pretty strong, they will be past this danger. This always happens in dry weather, so that if there should be rain when the Turneps come up, they will grow so fast, as to be in a few days out of danger from the fly; and it hath been found, that those, which have been sown in drills, have escaped the fly much better than those sown in broad-cast; but if foot is sown along the surface of each drill, it will be of great service to keep off the fly, and a small quantity of it will be sufficient for a large field, where the drills only are to be covered.

Another danger of the crops being destroyed is from the caterpillars, which very often attack them, when they are grown so large as to have six or eight leaves on a plant. The surest method of destroying these insects is to turn a large parcel of poultry into the field, which should be kept hungry, and turned early in the morning into the field; these fowls will soon devour the insects, and clear the Turneps. To this evil the Turneps, which are sown in drills, are not so much exposed, for as the ground between the rows will be kept stirred, the plants will be kept growing, so will not be in danger of suffering from these insects; for the parent insects never deposit their eggs upon any plants which are in health, but as soon as they are stunted, they are immediately covered with the eggs of these insects; and this holds in general with the vegetables as with animals, who are seldom attacked by vermin when they are in perfect health; whereas, when they become unhealthy, they are soon overspread with them, so that it is the disease which occasions the vermin, and not the vermin the disease, as is commonly imagined. Therefore as the plants will always be in greater health when the ground is well stirred about them, there will be less danger of their suffering from these enemies, when they are cultivated by the horse-hoe, than in the common way.

When the Turneps are sown in drills, it will be the best way to hoe between every other row at first, and some time after to hoe the alternate intervals, by which method the plants will receive more benefit from the often stirring the ground, than they would do if all the intervals were hoed at one time, and the plants will be in less danger of suffering from the earth being thrown up too high on some rows, while others may be left too bare of earth; but, when the earth has been thrown up on one side of the drill, it may be turned down again when the next interval is hoed, and this alternate moving of the earth will prepare the ground very well for the succeeding crop, as well as greatly improve the Turneps; but, as this plough cannot well be drawn nearer to the drills than two or three inches, the remaining ground should be forked to loosen the parts, and make way for the fibres of the roots to strike out into the intervals, otherwise, if the land is strong, it will become so hard in those places which are not stirred, as to stint the growth of the Turneps, and this may be done at a small expence; a good hand will perform a great deal of this work in a day, and, whoever will make the trial, will find their account in practising it, especially on all strong land, where the Turneps are much more liable to suffer from the binding of the ground, than they will be on a loose soil; but yet, in all sorts of ground, it will be of great service to practise this.

When the ground is thus stirred in every part, one ploughing will be sufficient, after the Turneps are eaten off the ground, to prepare it for the sowing of

R A P

Barley, or any other crop; so that there will be an advantage in this, when the Turneps are kept late on the ground, as will often be the case, especially when they are cultivated for feeding of ewes, because it is often the middle of April before the ground will be cleared; for late feed in the spring, before the natural Grass comes up, is the most wanted, where numbers of sheep and ewes are maintained, and one acre of Turneps will afford more feed than thirty acres of the best pasture at that season.

In Norfolk and some other counties, they cultivate great quantities of Turneps for feeding of black cattle, which turn to great advantage to their farms, for hereby they procure a good dressing for their land; so that they have extraordinary good crops of Barley upon the same ground, which would not have been worth the ploughing, if it had not been thus husbanded.

When the Turneps are fed off the ground, the cattle should not be suffered to run over too much of it at one time; for if they are not confined by hurdles to as much as is sufficient for them one day, the cattle will spoil three times the quantity of Turneps as they can eat, so that it is very bad husbandry to give them too much room; therefore the hurdles should be once or twice every day removed forward, and, if the Turneps are drawn out of the ground before the cattle or sheep are turned into the new inclosure, there will be less waste made, for they will then eat up the whole roots; whereas, if they are turned upon the Turneps growing, they will scoop the roots, and leave the rinds, which being hollow, the urine of the sheep will lodge in them; so that when they are forked out of the ground, the sheep will not eat any one of those roots which are thus tainted.

I cannot omit taking notice of a common mistake, which has generally prevailed with persons who have not been well informed to the contrary, which is, in relation to the mutton which is fattened with Turneps, most people believing it to be rank and ill tasted, whereas it is a known fact, that the best mutton this country affords is all fattened on Turneps; and that rank mutton, whose fat is yellow, is what the low marshy lands of Lincolnshire, and other rank pastures, produce.

In order to save good Turnep-seeds, you should transplant some of the fairest roots in February, placing them at least two feet asunder each way, observing to keep the ground clear from weeds, until the Turneps have spread so as to cover the ground, when they will prevent the weeds from growing; and when the seed-pods are formed, you should carefully guard them against the birds, otherwise they will devour it, especially when it is near ripe; at which time you should either shoot the birds as they alight upon the seed, or lay some bird-limed twigs upon it, whereby some of them will be caught; and, if they are permitted to remain some time, and afterwards turned loose, they will prevent the birds from coming thither again for some time, as I have experienced. When the seed is ripe, it should be cut up, and spread to dry in the sun; after which it may be threshed out, and preserved for use.

There have been many receipts for preventing the fly taking Turneps, but few of them deserve notice, therefore I shall only mention two or three which I have seen tried with success. The first was steeping the seeds in water with flower of brimstone mixed, so as to make it strong of the brimstone: another was steeping it in water with a quantity of the juice of Horse-Aloes mixed; both which have been found of use. The sowing of foot or Tobacco-dust over the young plants as soon as they appear above ground, has also been found very serviceable: in short, whatever will add vigour to the young plants will prevent their being destroyed by the fly, for these never attack them till they are stunted in their growth.

R A P H A N U S. Tourn. Inst. R. H. 229. tab. 114. Lin. Gen. Plant. 736. [of *radix*, easy, and *pairu*, to appear; q. d. a plant easily appearing, for this plant being

being sown, quickly puts forth out of the ground.] Radish; in French, *Raisfort*.

The CHARACTERS are,

The empalement of the flower is erect, and composed of four oblong leaves. The flower has four heart-shaped petals, placed in form of a cross, which spread open, and are narrow at their base; it hath four honey glands, one on each side the short stamina between them and the style, and one between each of the long stamina and the empalement; it hath six short stamina which are erect; two which are opposite, are the length of the empalement, the other four are as long as the base of the petals, terminated by single summits, and an oblong swelling germen narrowed the length of the stamina, with scarce any style, crowned by a beaded stigma. The germen afterward becomes an oblong, smooth, spongy pod having an acute point, swelling and almost jointed, having two cells divided by an intermediate partition, and filled with roundish seeds.

This genus of plants is ranged in the second section of Linnæus's fifteenth class, which contains those plants whose flowers have four long and two shorter stamina, and their seeds are included in pods.

The SPECIES are,

1. *RAPHANUS (Sativus) filiquis teretibus torosis bilocularibus.* Hort. Cliff. 340. *Radish with taper pods, having two cells. Raphanus minor oblongus.* C. B. P. 96. *Smaller oblong Radish, or the common Radish.*
2. *RAPHANUS (Rotundus) radice rotundâ. Round-rooted Radish, or small, round, Naples Radish.*
3. *RAPHANUS (Orbiculatis) radice orbiculatâ depressâ. Radish with an orbicular depressed root. Raphanus major, orbicularis vel rotundus.* C. B. P. 96. *Greater orbicular, or round Radish, commonly called Turnep-rooted, or white Spanish Radish.*
4. *RAPHANUS (Niger) radice fusiformi. Radish with a spindle-shaped root. Raphanus niger.* C. B. P. 96. *The black Spanish Radish.*
5. *RAPHANUS (Chinensis) oleiferus.* Lin. Sp. 935. *China oily Radish.*
6. *RAPHANUS (Raphanistrum) filiquis teretibus articulatis lævibus unilocularibus.* Hort. Cliff. 340. *Radish with smooth, taper, jointed pods having one cell. Raphistrum flore albo, filiquâ articulatâ.* C. B. P. 95. *White flowering Charlock with a jointed pod.*

The last sort grows naturally on arable lands in many parts of Europe, so is seldom admitted into gardens.

The other five sorts are supposed to be only seminal variations; but from forty years experience, I have never found either of these to vary from one to the other sort; and I am certain whoever will make the trial, by saving the seeds of each carefully without mixture, will always find the plants prove the same as the seeds were saved from.

The first sort here mentioned is that which is commonly cultivated in kitchen-gardens for its root, of which there are several varieties, as the small-topped, the deep red, the pale red or salmon, and the long-topped striped Radish; all which are varieties arising from culture. The small-topped sort is most commonly preferred by the gardeners near London, because they require much less room than those with large tops, and may be left much closer together; and, as the forward Radishes are what produce the greatest profit to the gardener, these being commonly sown upon borders near hedges, walls, or pales, if they are of the large-topped sort, will be apt to grow mostly to a top, and not swell so much in the root as the other, especially if they are left pretty close.

The seasons for sowing this seed are various, according to the time when they are designed for use; but the earliest season is commonly the end of October, or beginning of November, that the gardeners near London sow them to supply the markets; and these, if they do not miscarry, will be fit for use in the beginning of March following, which is full as soon as most people care to eat them. These are commonly sown on warm borders near walls, pales, or hedges, where they may be defended from the cold

winds; but there are some who sow Radish-seeds among other crops the middle of September, and, if these are not destroyed by frost, they will be fit for use early in February; but these must be eaten while they are young, for they soon grow sticky and strong.

The second sowing is commonly about Christmas, provided the season be mild, and the ground in a fit condition to work; these are also sowed near shelter, but not so near pales and hedges as the first sowing. If these are not destroyed by frost, they will be fit for use the beginning of April; but in order to have a succession of these roots for the table through the season, you should repeat sowing of their seeds once a fortnight, from the middle of January till the beginning of April, always observing to sow the latter crops upon a moist soil and in an open situation, otherwise they will run up and grow sticky before they are fit for use.

Many of the gardeners near London sow Carrot-feed with their early Radishes, so that when their Radishes are killed, which sometimes happens, the Carrots will remain; for the seeds of Carrots commonly lie in the ground five or six weeks before they come up, and the Radishes seldom lie above a fortnight under ground at that season, so that these are often up and killed, when the Carrot-feed remains safe in the ground; but, when both crops succeed, the Radishes must be drawn off very young, otherwise the Carrots will be drawn up so weak, as not to be able to support themselves when the Radishes are gone.

It is also a constant practice with these gardeners to mix Spinach-feed with their latter crops of Radishes, so that when the Radishes are drawn off, and the ground cleaned between the Spinach, it will grow prodigiously, and in a fortnight's time will as completely cover the ground, as though there had been no other crop. And this Spinach, if it be of the broad-leaved kind, will be larger and fairer than it commonly is when sown by itself; because where people have no other crop mixed with it, they commonly sow it too thick, whereby it is drawn up weak, but here the roots stand pretty far apart, so that after the Radishes are gone, they have full room to spread; and if the soil be good, it is a prodigious size this Spinach will grow to before it runs up for seed; but this husbandry is chiefly practised by such gardeners as pay very dear for their land, and are obliged to have as many crops in a year as possible, otherwise they could not afford to pay such large rents.

When the Radishes are come up, and have got five or six leaves, they must be pulled up where they are too close, otherwise they will draw up to a top, but the roots will not increase their bulk. In doing of this, some only draw them out by hand, which is a tedious method; but the best way is to hoe them with a small hoe, which will stir the ground, and destroy the young weeds, and also promote the growth of the Radishes and Spinach. The distance which these should be left, if for drawing up small, may be three inches, but if they are to stand until they are pretty large, six inches are full near enough, and a small spot of ground will afford as many Radishes at each sowing, as can be spent in a family while they are good.

If you intend to save seeds of your Radishes, you should, at the beginning of May, prepare a spot of ground in proportion to the quantity of seeds intended (but you should always make allowance for bad seasons, because it often happens, in a very dry season, that there will not be a fourth part of the quantity of seeds upon the same proportion of ground as there will be in a moist season, though in a dry year the seeds will ripen best.) This ground should be well dug and levelled; then you should draw up some of the straitest and best coloured Radishes (throwing away all such as are short, and that branch out in their roots;) the Radishes should be planted in rows three feet distance, and two feet asunder in the rows, observing, if the season be dry, to water them until they have taken root; after which they will require no farther care, but only to hoe down the weeds between them

R A P

them, until they are advanced so high as to spread over the ground, when they will prevent the growth of weeds.

When the seed begins to ripen, you should carefully guard it against the birds, for these will otherwise destroy it. When it is ripe (which you may know by the pods changing brown,) you should cut it, and spread it in the sun to dry; after which you should thresh it out, and lay it up for use, where the mice cannot come to it, otherwise they will eat it up. The small round-rooted Radish is not very common in England, but in many parts of Italy it is the only sort cultivated; the roots of this kind are very white, round, small, and very sweet. This may be propagated in the same manner as the common sort, but with this difference only, viz. That this must not be sown till the beginning of March, and the plants should be allowed a greater distance. The seeds of this kind are very subject to degenerate, when saved in England, unless those which are planted for seeds are at such a distance from the common sort, as that the farina of one cannot mix with the other.

The other round-rooted Radishes are seldom cultivated in England, but those who have a mind to have them, may sow them in the same manner as the last.

The black and white Spanish Radishes are commonly cultivated for medicinal use, though there are some persons who are very fond of them for the table. These are commonly sown about the middle of July, or a little earlier, and are fit for the table by the end of August, or the beginning of September, and will continue good till the frost spoils them. These must be thinned to a greater distance than the common sort, for the roots of these grow as large as Turneps, therefore should not be left nearer together than six or eight inches.

Some persons who are very curious to have these roots in winter, draw them out of the ground before the hard frost comes on, and lay them up in dry sand in the same manner as is practised for Carrots, being careful to guard them from wet and frost, and by this method they preserve them till the spring.

RAPISTRUM. See SINAPIS.

RAPUNCULUS. Tourn. Inst. R. H. 113. tab. 38. Phyteuma. Lin. Gen. Plant. 203. Rampion.

The CHARACTERS are,

The empalement of the flower is of one leaf, divided into five acute parts sitting upon the germen. The flower hath one petal, which is starry, spreading open, and cut into five linear segments which are recurved; it hath five stamina which are shorter than the petal, terminated by oblong summits. The germen, which is situated under the flower, supports a slender recurved style crowned by an oblong, twisted, three-pointed stigma. It afterward becomes a roundish capsule with three cells, filled with small roundish seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, in which those plants are placed, whose flowers have five stamina and one style.

The SPECIES are,

1. RAPUNCULUS (*Spicatus*) spica oblonga, capsulis bilocularibus, foliis radicalibus cordatis. Rampion with an oblong spike of flowers, capsules containing two cells, and the lower leaves heart-shaped. Rapunculus spicatus. C. B. P. 92. Spiked Rampion.
2. RAPUNCULUS (*Comosus*) fasciculo terminali sessili, foliis dentatis, radicalibus cordatis. Rampion with flowers growing in bunches terminating the stalks, indented leaves, and those at the bottom heart-shaped. Rapunculus Alpinus corniculatus. C. B. P. 93. Horned Alpine Rampion.
3. RAPUNCULUS (*Hemisphericus*) capitulo subrotundo, foliis linearibus integerrimis. Rampion with roundish heads, and linear entire leaves. Rapunculus folio gramineo. Tourn. Inst. 113. Rampion with a Grass leaf.
4. RAPUNCULUS (*Pauciflorus*) capitulo subfolioso, foliis omnibus lanceolatis. Rampion with heads which are leafy, and all the leaves spear-shaped. Rapunculus Al-

R A P

pinus parvus comosus. J. B. 2. p. 811. Small, Alpine, hairy Rampion.

5. RAPUNCULUS (*Orbicularis*) capitulo subrotundo, foliis serratis radicalibus cordatis. Rampion with roundish heads and sawed leaves, the lower ones of which are heart-shaped. Rapunculus flore globoso, purpureo. J. B. 2. 810. Rampion with a purple globular flower. These are all of them hardy plants, which will thrive in the open air. They are propagated by seed, which should be sown in autumn, for if they are kept out of the ground till the spring, they frequently fail, or at least lie a year in the ground. These seeds should be sown on a bed of fresh undunged earth where they are designed to remain, for they do not thrive so well when they are transplanted; therefore the best method is to make small drills cross the bed about eighteen inches asunder, and sow the seeds therein; then cover them lightly over with earth, for if they are buried too deep, they will rot in the ground. In the following spring the plants will come up, when they should be diligently weeded, which is all the care they require; only they should be thinned where they are too close, so as to leave them six or seven inches apart in the rows, and afterward they require no farther attention but to keep them clear from weeds. In June the plants will flower, and if the summer prove favourable, they will produce ripe seeds.

As these plants do not continue above two or three years, there should be seeds sown every other year to continue the sorts, for they are plants which require little trouble to cultivate them, and their flowers make a pretty variety in large gardens, therefore they may be allowed a place amongst other hardy flowers.

RAPUNTIIUM. Tourn. Inst. R. H. 163. tab 51. Lobelia. Lin. Gen. Plant. 897. Rampions, or Cardinal's-flower.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into five linear segments, the two upper being larger than the other. The flower is of one petal; it hath a long cylindrical tube which is a little curved, and divided at the brim into five segments, two of which compose the upper lip, and are smaller than the three lower which compose the under; it hath five awl-shaped stamina the length of the tube, terminated by oblong summits which coalesce at the top in form of a cylinder; but open in five parts at their base, having an acute germen situated below the flower, supporting a cylindrical style crowned by a hairy obtuse stigma. The germen afterward becomes an oval capsule opening at the top, filled with small seeds.

This genus of plants is ranged in the second section of Tournefort's third class, which includes the herbs with an anomalous flower of one petal, having a tube ending in a tongue. Dr. Linnæus has joined the plants of this genus to that of Plumier's Lobelia, making them but one genus; but, as the Lobelia of Plumier has a fleshy berry inclosing a stone with two seeds, and the Rapuntium hath a dry capsule, they should be separated.

The SPECIES are,

1. RAPUNTIIUM (*Cardinalis*) caule erecto, foliis lanceolatis serratis, spica terminali. Cardinal's-flower with an erect stalk, spear-shaped sawed leaves, and a spike of flowers terminating the stalk. Rapuntium maximum, coccineo spicato flore. Col. in Rech. 880. The largest Rapuntium with a spike of scarlet flowers, commonly called scarlet Cardinal's-flower.
2. RAPUNTIIUM (*Siphiliticum*) caule erecto, foliis ovato-lanceolatis crenatis, calycum sinibus reflexis. Cardinal's-flower with an erect stalk, oval, spear-shaped, crenated leaves, and the sinuses of the empalements reflexed. Rapuntium Americanum, flore dilute cæruleo. H. R. Par. 105. American Cardinal's-flower with a pale blue flower, commonly called the blue Cardinal's-flower.
3. RAPUNTIIUM (*Cliffortianum*) caule erecto, foliis cordatis obsolete dentatis petiolatis, floribus sparsis thyrsis longissimo. Cardinal's-flower with an erect stalk, heart-shaped leaves which are somewhat indented, with foot-

stalks, and the longest spike of flowers which are placed thinly. *Rapuntium Americanum trachelii folio, flore purpurascens. Plum. Cat. 5. American Cardinal's-flower, with a Throatwort leaf and a purplish flower.*

4. *RAPUNTIIUM (Urens)* caule erecto, foliis inferioribus subrotundis crenatis, superioribus lanceolatis serratis, spicâ terminali. *Rapuntium with an erect stalk, the lower leaves roundish and crenated, the upper spear-shaped and sawed, and a spike of flowers terminating the stalk. Rapuntium urens, soloniense. H. R. Bloes. Stinging Cardinal's-flower of Blois.*

5. *RAPUNTIIUM (Inflatum)* caule erecto, foliis ovatis subferratis, pedunculo longioribus, capsulis inflatis. *Cardinal's-flower with an erect stalk, oval leaves which are somewhat sawed and longer than the foot-stalks, and swelling seed-vessels. Lobelia caule erecto brachiato, foliis ovato-lanceolatis obsolete incis, capsulis inflatis. Hort. Cliff. 500. Lobelia with an erect branching stalk, oval spear-shaped leaves a little cut, and swollen seed-vessels.*

6. *RAPUNTIIUM (Hirtum)* foliis ovalibus crenatis lanatis, floribus lateralibus solitariis. *Cardinal's-flower with oval crenated leaves which are downy, and flowers growing singly from the sides of the stalks. Rapuntium foliis subrotundis hirtis, flore ex alis solitario. Burn. Afr. 105. tab. 40. Rapuntium with roundish hairy leaves, and solitary flowers proceeding from their wings.*

7. *RAPUNTIIUM (Longiflorum)* foliis lanceolatis dentatis, pedunculis brevissimis lateralibus tubo corollæ longissimo. *Cardinal's-flower with spear-shaped indented leaves, very short foot-stalks to the flowers which proceed from the sides of the stalks, and a very long tube to the petal. Rapunculus aquaticus, foliis cichorii flore albo tubo longissimo. Sloan. Hist. Jam. 1. p. 158. Aquatic Rampion with a Cicory leaf, and a white flower having the longest tube.*

8. *RAPUNTIIUM (Erinum)* caule patulo ramoso foliis lanceolatis subdentatis, pedunculis longissimis. *Rapuntium with a spreading branching stalk, spear-shaped leaves which are somewhat indented, and very long foot-stalks to the flowers. Campanula minor Africana, erini facie, flore violaceo, caulibus erectis. H. L. 110. Smaller African Bell-flower with the appearance of Erinus, a Violet flower, and an upright stalk.*

9. *RAPUNTIIUM (Erinoides)* caulibus procumbentibus, foliis lanceolatis serratis, pedunculis lateralibus. *Cardinal's-flower with trailing stalks, spear-shaped sawed leaves, and foot-stalks proceeding from their sides. Campanula minor Africana, erini facie, caulibus procumbentibus. H. L. 108. Smaller African Bell-flower with the appearance of Erinus, and trailing stalks.*

The first sort grows naturally by the side of rivers and ditches in great part of North America, but has been many years cultivated in the European gardens for the great beauty of its scarlet flowers. The root is composed of many white fleshy fibres; the lower leaves are oblong, a little sawed, and of a dark purplish colour on their upper side; the stalks are erect, and rise about a foot and a half high; they are garnished with spear-shaped leaves about three inches long, and one and a half broad in the middle, a little sawed on their edges, having very short foot-stalks, and are placed alternately; the stalk is terminated by a spike of flowers of an exceeding beautiful scarlet colour; these have a pretty long tube, which is a little incurved, but at the top is cut longitudinally into five segments; two upper, which are the smallest, are greatly reflexed, the three under which form the lower lip, are larger, and spread open. These appear the latter end of July and in August, when they make a fine appearance for a month or more, and when the autumn proves favourable, they will produce good seeds here.

This is propagated by seeds, which, when they ripen in England, should be sown in autumn in pots filled with rich kitchen-garden earth, and placed under a common hot-bed frame; or, if the seeds come from the country where the plants grow naturally, they should be sown in the same way as soon as they arrive, for if they are kept out of the ground till spring,

they will lie a year in the ground before they vegetate. The pots in which these seeds are sown should be exposed to the open air at all times when the weather is mild, but they must be screened from the frost, and the very hard rain in winter. In the spring the plants will appear, when they should have as much free air as possible in mild weather, and if the spring proves dry, they must be frequently refreshed with water. As soon as they are fit to remove, they should be each planted in a separate small pot filled with the same rich earth, and placed in the shade till they have taken new root; then they may be placed where they may have the morning sun, in which situation they may remain till autumn. During the summer, they must be duly watered in dry weather, and when the roots have filled the pots, they should be removed into larger. In autumn they must be placed under a common frame to screen them from hard frost, but they should enjoy the open air at all times when the weather is mild. The spring following they should be new potted, and placed where they may have the morning sun, always observing to water them duly in dry weather, which will cause their stalks to be stronger, and produce larger spikes of flowers in August. These will continue long in beauty, if they are not too much exposed to the sun, and, if the autumn proves warm, the seeds will ripen well in England. The roots of this plant will sometimes last two or three years, and produce offsets for increase, but they will not flower so strong as the seedling plants, therefore an annual supply of them should be raised. There are many who propagate this plant by cutting their stalks into proper lengths, and plant them in pots filled with good earth, or into an east border, covering them close with glasses. These frequently take root, so produce young plants, but they are not so good as the seedlings.

The plants of this sort will live in the full ground if they are protected from hard frost in winter, and they will flower stronger than those in pots.

The second sort grows naturally at Campeachy, from whence the late Mr. Robert Millar sent the seeds; this hath a fibrous root like the first. The stalks are much larger, and rise a foot higher; they are closely garnished with leaves which are above four inches long, and half an inch broad, very smooth and entire, ending in acute points; they are terminated by short spikes of flowers which are larger than those of the first sort, but are of the same beautiful scarlet colour, and appear about the same time with them.

This is propagated by seeds in the same way as the first, but the plants are not so hardy, therefore require to be placed in a moderate stove in winter, and in summer they should be placed in a deep frame, where they may be covered with glasses in bad weather, but enjoy the free air at all times when the weather is favourable. With this management the plants flowered very well in the Chelsea Garden, but they did not perfect seeds.

The third sort grows naturally in Virginia, but has been long an inhabitant of the English gardens; this hath a perennial fibrous root. The leaves are smooth, oval, spear-shaped, and a little indented on their edges; the stalks rise a foot and a half high, and are garnished with leaves like those at the bottom, which are gradually smaller to the top, sitting close to the stalk. The flowers come out from the wings of the leaves; they are of a pale blue colour, and have large empalements whose edges are reflexed; they appear a little earlier in July than the first sort, and the seeds frequently ripen in England.

It is propagated in the same way as the first sort, and the plants require the same culture.

The fourth sort grows naturally in Jamaica, from whence the late Dr. Houstoun sent the seeds; this is an annual plant. The stalk rises about a foot high, then divides into four or five smaller, which grow erect. The lower part is garnished with heart-shaped smooth leaves, about one inch and a half long, and three

R A P

three quarters of an inch broad at the base, lessening to a point at the end; they have small indentures on their borders, and stand upon short foot-stalks. The upper slender stalks are thinly garnished with small purplish flowers to the top, and these are succeeded by small seed-vessels which ripen in autumn. When the seeds are permitted to scatter on the pots which stand near them, and those are sheltered from the frost, the plants will come up plentifully the following spring; or, if they are sown in pots in autumn, and sheltered in the winter, the plants will arise the following spring; and these should be transplanted into separate small pots, placing them under a frame, where they will flower in June and July, and their seeds will ripen in September, and the plants will then decay.

The fifth sort grows naturally in the forests about Blois in France; this is an annual plant. The root is composed of many fleshy fibres; the stalk rises about two feet high, and is garnished with spear-shaped leaves near three inches long, and one broad in the middle; they are very thin, and are sawed on their edges, fitting close to the stalk; the upper part of the stalk is garnished with very small leaves, and from their base arise the flowers, which are of a bright blue colour. These appear in July, and are succeeded by roundish seed-vessels with holes at the top, which are filled with small red seeds.

The seeds of this plant should be sown in autumn in pots filled with loamy earth, and placed under a hot-bed frame in winter, and when they come up in the spring, they should be transplanted either into a border of soft loamy earth, or into separate pots, shading them till they have taken new root; and afterward the must be duly watered in dry weather, which will cause them to flower strong, and produce good seeds annually.

The sixth sort grows naturally in North America; this is a biennial plant in England, which rarely flowers the same year as the plants come up, but decays soon after the seeds are ripe. The stalks of this are channelled and hairy; they grow erect to the height of two feet, and are garnished with thin oval leaves about two inches long, and one broad in the middle, sitting close to the stalk; they are of a light green, and a little sawed on their edges. The flowers stand upon long slender foot-stalks which come out from the wings of the leaves, and form a loose spike which terminate the stalk; they are small, and of a light blue colour. This flowers in July, and the seeds ripen in September. This is propagated by seeds, which should be sown in autumn, in pots filled with rich earth, and treated in the same way as the first sort.

The seventh sort grows naturally at the Cape of Good Hope; this is a biennial plant; the stalks rise a foot and a half high, they are covered with a hairy down, and are purplish toward the bottom; the leaves are oval, two inches and a half long, and an inch and a quarter broad, of a deep green colour, a little hairy on their under side, and sit close to the stalks. The flowers stand upon long slender foot-stalks, which come out from the bosom of the leaves, sometimes one proceeding from a joint, and at others they come out opposite on each side the stalk, each foot-stalk sustaining one pale blue flower, which being small makes but little appearance. This flowers about the same time with the former, and may be propagated in the same way.

The eighth sort grows naturally in moist places, on most of the islands in the West-Indies. This is also a biennial plant, whose root is composed of a few strong ligneous fibres, which strike deep in the ground; the stalk rises about eight or nine inches high, and is closely garnished with leaves on every side; these are four inches long and half an inch broad, very deeply indented on their edges; they are hairy, of a deep green, and sit close to the stalks. The flowers come out at every joint from the wings of the leaves, standing upon very short foot-stalks; the tube of the

R A U

flower is from three to four inches long, very slender, and is deeply cut at the top into five segments, which spread open; they are white, and appear in June, and are succeeded by turgid seed-vessels, crowned by the five segments of the petal, having three holes at the top, and filled with small grayish seeds. The seeds of this sort should be sown soon after it is ripe, in pots filled with rich earth, and plunged into the tan-bed in the stove, observing to refresh the earth frequently with water. In the spring these pots may be removed, and plunged into a hot-bed, which will soon bring up the plants: when these are fit to remove, they should be each transplanted into a separate small pot filled with rich earth, and plunged into a fresh hot-bed, shading them from the sun till they have taken new root; then they may be treated in the same way as other tender plants from the same country, giving them a large share of air in warm weather, and frequently refreshing them with water. In autumn the plants must be plunged into the tan-bed of the stove, where they will flower the following summer and produce ripe seeds, soon after which the plants will decay. If the seeds of this plant are brought from the West-Indies, they should be sown as soon as they arrive, in pots filled with rich earth; and if it happens in the winter, the pots should be plunged into the tan-bed in the stove; but if it is in the spring or summer, they may be plunged into a hot-bed in the common frames. These seeds when sown in the spring, seldom grow the same year, therefore the following autumn the pots should be removed into the stove, and managed according to the above directions.

The ninth sort grows naturally at the Cape of Good Hope; this is an annual plant; the stalks are slender, branching, and spread out on every side; they rise about a foot high, and are garnished with small spear-shaped leaves which are indented on their edges, and sit close to the branches. The flowers are small and blue; they stand upon very slender long foot-stalks, and appear in July; these are succeeded by small roundish seed-vessels, filled with small seeds which ripen in September. If the seeds of this sort are sown in autumn, they will succeed much better than when they are sown in spring: these may be sown in pots, and sheltered under a common hot-bed frame in winter, exposing them to the open air at all times in mild weather, but screening them from the frost; and in the spring, the pots should be plunged into a moderate hot-bed, which will soon bring up the plants; when these are fit to remove, they should be each planted in a separate small pot filled with rich earth, and plunged into a moderate hot-bed again, shading them from the sun till they have taken new root; then they must have a large share of free air at all times when the weather is mild; and as the plants grow strong, they should be gradually hardened to bear the open air, into which they should be removed in June, placing them in a sheltered situation, where they will flower in July, and if the season proves favourable, the seeds will ripen in September; but if the season should prove cold, it will be proper to remove one or two plants into a glass-case, to obtain good seeds.

The tenth sort comes from the Cape of Good Hope: this hath trailing stalks, and the leaves are sawed on their edges, and the foot-stalks come out from the side of the branches, in which it differs from the last sort. It may be propagated by seeds, and treated in the same manner as the last.

RAUVOLFIA. Plum. Nov. Gen. 19. tab. 40. Lin. Gen. Plant. 259.

The name was given to this genus of plants by Father Plumier, who was the person that discovered it in America, in honour of Leonard Rauwolf, who was a curious botanist, and flourished about the year 1583. He travelled into the Holy Land, and several other places in the east, and published his travels in High Dutch, which were translated into English under the inspection of the great Mr. Ray.

The

The CHARACTERS are,

The flower has a small permanent empalement of one leaf, cut into five segments at the top. The petal is funnel-shaped; the tube is cylindrical, globular at the base, and is cut at the brim into five parts. It has five stamina which are a little shorter than the tube, terminated by erect summits, and a roundish germen supporting a short style, crowned by a beaded stigma. The germen afterward becomes a globular berry with two cells, inclosing one compressed seed in each.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. RAUVOLFIA (*Canescens*) subpubescens. Lin. Sp. Plant. 303. *Hairy Rauwolfia*. Rauwolfia tetraphylla latifolia. Plum. Nov. Gen. 19. *Broad four-leaved Rauwolfia*.
2. RAUVOLFIA (*Nitida*) glaberrima nitidissima. Lin. Sp. 303. *Smooth neat Rauwolfia*. Rauwolfia tetraphylla angustifolia. Plum. Nov. Gen. 19. *Narrow four-leaved Rauwolfia*.

Both these sorts grow naturally in the warmest parts of America; Mr. Robert Millar sent the seeds of them from Carthagenia in New Spain, where he observed the shrubs growing in great plenty. These rise with several ligneous stalks from the foot, which grow seven or eight feet high, sending out a few small side branches, covered with a smooth green bark when young, but as they are older their bark changes to a gray. The leaves are placed by fours at each joint round the branches; those of the first sort are two inches and a half long, and an inch and a half broad in the middle, a little hairy, of a light green, and have a few slight indentures on their edges; the leaves of the other sort are full as long, but are a third part narrower, of a thinner substance, and much smoother. These differences continue in the plants which are raised from seeds, for I have several times propagated them both from seeds, and have constantly found the seeds produce the same as the plants from which they were taken. The flowers are produced on slender foot-stalks, which arise from the wings of the leaves; they are tubulous, and globular at their base, and are succeeded by roundish berries about the size of those of the Privet, which turn black when they are ripe. These plants flower most part of the summer, and the fruit ripens in autumn and winter; the leaves and stalks of these plants have a milky juice, which flows out if they are broken.

These are propagated by seeds, which should be sown in autumn soon after they are ripe; for if they are kept out of the ground till spring, the plants rarely come up the same year; and this is frequently the case with those seeds which are brought to England.

The seeds of these plants should be sown in pots filled with fresh earth, and plunged into a hot-bed of tanners bark; for as they are very hard, so they frequently remain a long time in the ground; therefore when they are in pots, they may be shifted from one bed to another as their heat decays. When the plants come up, they must be frequently refreshed with water, but it must not be given them in large quantities; for as the plants are succulent and full of a milky juice, so they are in danger of rotting with too much moisture. They should also have a large share of fresh air admitted to them in warm weather, and when they are about two inches high, they should be transplanted each into a separate small pot filled with fresh light earth, and plunged into a hot-bed again, observing to shade them from the sun until they have taken new root; after which time they should have free air admitted to them every day, in proportion to the warmth of the season. In this hot-bed the plants may remain till toward Michaelmas, when they should be removed into the stove, and plunged into the tanners bark, where they must be kept warm, and not have too much moisture in cold weather.

As these plants are natives of very hot countries, they will not live in the open air in England, therefore

they should constantly remain in the stove; and if they are continued in the bark-bed, they will thrive much faster than when they are placed on stands in a dry stove. But in the summer season they should have a large share of fresh air admitted to them, and the leaves of the plants must be now and then washed with a sponge, to clear them from the filth they are apt to contract; which, if suffered to remain, will retard the growth of the plants. Where due care is taken of them, they will thrive very fast, and the second year will produce flowers, and continue so to do for many years, and will perfect their seeds in England. They may also be propagated by cuttings, which should be laid to dry for two or three days before they are planted; and then should be plunged into a moderate hot-bed of tanners bark, observing to shade them until they have taken root, after which time they may be treated as the seedling plants.

R E S E D A. Tourn. Inst. R. H. 423. tab. 238. Lin. Gen. Plant. 535. Bastard-rocket.

The CHARACTERS are,

The empalement of the flower is of one leaf, cut into several segments almost to the bottom, and is permanent. The petals of the flower are unequal, and generally trifid, having a honey gland on their base the length of the empalement. The honey glands are plain, erect, and produced from the upper side of the receptacle, between the stamina and the place of the upper petal, joining with the base of the petals, dilating from the sides. It hath fifteen or sixteen short stamina, terminated by erect obtuse summits; and a gibbous germen sitting upon very short styles, crowned by a single stigma. The germen afterward becomes a gibbous angular capsule of one cell, with an aperture between the styles, filled with kidney-shaped seeds fastened to the angles of the capsule.

This genus of plants is ranged in the third section of Linnæus's eleventh class, which includes those plants whose flowers have from eleven to nineteen stamina, and three styles.

The SPECIES are,

1. RESEDA (*Vulgaris*) foliis pinnatis, foliolis integris alternis floribus tetragynis. Bastard-rocket with winged leaves, whose lobes are entire, placed alternate, and have four styles to the flower. Reseda vulgaris. C. B. P. 100. Common Bastard-rocket.
2. RESEDA (*Crispa*) foliis omnibus trifidis, inferioribus pinnatis. Hort. Cliff. 213. Bastard-rocket with all the leaves trifid, and the lower ones winged. Reseda crispa Gallica. Bocc. Sic. 77. French curled Bastard-rocket.
3. RESEDA (*Phyteuma*) foliis integris trilobisque, calycibus sexpartitis maximis. Hort. Cliff. 412. Bastard-rocket with entire and trifid leaves, and the largest empalement to the flower. Reseda minor vulgaris. Tourn. Inst. R. H. 413. Lesser common Bastard-rocket.
4. RESEDA (*Undata*) floribus trigynis, tetragynisque calycibus quinquepartitis, foliis pinnatis undularis. Lin. Sp. Plant. 644. Bastard-rocket with trifid and quadrifid flowers, whose empalements are cut into five parts, and winged waved leaves. Reseda minor alba, dentatis foliis. Barrel. Icon. 588. Smaller white Bastard-rocket with indented leaves.
5. RESEDA (*Alba*) foliis pinnatis, floribus tetragynis, calycibus sexpartitis. Lin. Sp. Plant. 645. Hort. Upsal. 149. Bastard-rocket with winged leaves, flowers having four styles, and an empalement cut into six parts. Reseda foliis calcitrapæ flore albo. Mor. Hort. R. Bl. Bastard-rocket with Star Thistle leaves, and a white flower.
6. RESEDA (*Odorata*) foliis integris trilobisque, calycibus florum æquantibus. Lin. Sp. Plant. 646. Bastard-rocket with entire three-lobed leaves, whose empalement is equal with the petals of the flower, commonly called sweet Reseda, or Mignonette d'Egypte.
7. RESEDA (*Canescens*) foliis subulatis sparsis. Sauv. Monsp. 41. Bastard-rocket with wool-shaped leaves placed thinly. Sesamoides flore albo, foliis canescentibus. Tourn. Inst. R. H. 424. Bastard Sesamum with a white flower and hoary leaves.
8. RESEDA (*Luteola*) foliis lanceolatis integris, calycibus quadrifidis. Lin. Sp. Plant. 448. Bastard-rocket with spear-shaped entire leaves, and quadrifid empalements. Lu-

teola

teola herba falicis folio. C. B. P. 100. Dyer's Weed, or wild Woad, by some called Weld.

The first sort grows naturally in the south of France, Italy, and Spain. This is a biennial plant, which flowers and seeds the second year, and perishes soon after. The root is long, white, and a little ligneous; the leaves are unequally winged, and the lobes are entire; the stalks are channelled, rising two feet high, garnished with leaves like those below, but are smaller, and are terminated by long loose spikes of pale yellow flowers, composed of several unequal petals; the two upper are the largest, the side ones less, and the lower are so small as to be scarce conspicuous; they are all of a singular figure, and appear as if one leaf came out of two others. In the middle are situated many stamina terminated by yellow summits, and at the bottom a three-cornered germen, which afterward turns to a three-cornered seed-vessel, having three or four holes at the top, and filled with black seeds.

The second sort grows naturally in chalky land in many parts of England, and has been supposed to be the common sort, it being our common sort in England, but the former is more common abroad, and is so titled; the lower leaves of this are winged, and every lobe is cut into three small parts, and are curled, having some small indentures on their edges. The stalks rise about the same height as those of the former, and are terminated by longer and looser spikes of flowers; the flowers are paler and approach to a white. This flowers in June, and the seeds ripen in September.

The third sort grows naturally in the south of France and Italy; this is an annual plant, which has generally a single fleshy tap-root running deep in the ground, sending out several trailing stalks near a foot long, which divide into smaller branches, garnished with small leaves, some of which are wedge-shaped and entire, others are cut into three obtuse segments. The ends of the branches are terminated by loose spikes of flowers, standing upon pretty long foot-stalks. The empalement of the flower is large, divided into six segments almost to the bottom; the flowers are white, and shaped like those of the other sorts. It flowers in July, and the seeds ripen in autumn.

The fourth sort grows naturally in Italy and Spain; this is a biennial plant, the lower leaves are unequally winged, some of the intermediate lobes or segments being much less than the others, and of different shapes. The stalks rise two feet and a half high, garnished with smaller disformed winged leaves, indented on their edges. The flowers are produced in slender loose spikes at the top of the stalks; they are small and white, of the same shape with the others, appearing in June, and the seeds ripen in September.

The fifth sort grows naturally in the south of France; it is a biennial plant; the lower leaves are large, winged, and composed of many narrow lobes or segments placed alternate, which are of a grayish colour; the stalks rise two feet and a half high, and are garnished with the like leaves, which diminish in their size to the top; the stalks are terminated by shorter and thicker spikes of flowers than either of the former, which are white, and shaped like those of the other species. It flowers in June, and the seeds ripen in August.

The sixth sort is supposed to grow naturally in Egypt; the seeds of this were sent me by Dr. Adrian Van Royen, the late professor of botany at Leyden. The root of this plant is composed of many strong fibres, which run deep in the ground, from which come out several stalks about a foot long, which divide into many small branches; these are garnished with oblong leaves, some of which are entire, and others are divided into three parts; they are about two inches long, and three quarters of an inch broad in the middle, ending in oval points, of a deep green colour. The flowers are produced in loose spikes at the end of the branches; they stand upon pretty long foot-

stalks, have large empalements, and are of an herbaceous white colour, and smell very like fresh Raspberries, which occasions its being much cultivated in the English gardens. This plant is so like the third sort, as to be taken for the same by some, but the flowers of the third have no scent; so that those who have been imposed on, by having the seeds of the third sort sent them for this, have supposed the plant was degenerated.

The seventh sort grows naturally upon the mountains in Spain; this hath a perennial root, from which arise a few slender ligneous stalks a foot and a half high, which are thinly garnished with linear obtuse leaves, of a grayish colour; the upper part of the stalk is garnished for a good length with small, whitish, purple flowers, ranged in a very loose spike, sitting close to the stalk. These appear the latter end of May, and the seeds ripen in August.

The eighth sort grows naturally upon dry banks and old walls in many parts of England, but is cultivated in some places for the dyer's use. This is now generally believed to be the plant, with which the ancient inhabitants of this island painted themselves, and not the Woad, as has been by some supposed; for the Dyer's Weed is a native here, whereas the Woad has been since introduced into this country. This is a biennial plant; the root is composed of a few ligneous fibres; the leaves are four inches long, and half an inch broad, entire, and ending in obtuse points; these the first year spread circularly near the ground, and have some gentle wavings on their edges; the stalks rise three feet high, and are garnished with leaves of the same shape with those at bottom. They are terminated by long loose spikes of yellowish flowers, which appear the latter end of June, and the seeds ripen in September.

The five sorts first mentioned, and also the seventh, are seldom cultivated in gardens except for the sake of variety, having very little beauty to recommend them, and being of no use; but whoever has a mind to have them, need only sow their seeds in autumn, and when the plants come up, if they are thinned and kept clean from weeds, it is all the culture they require; and if their seeds are permitted to scatter, the plants will come up in plenty, and sometimes become troublesome weeds.

The seeds of the sixth sort should be sown on a moderate hot-bed in March, and when the plants are strong enough to transplant, they should be pricked out upon another moderate hot-bed to bring them forward; but they should have a large share of air in warm weather, otherwise they will draw up weak. About the latter end of May the plants may be planted out, some into pots, to place near the apartments, and others into warm borders, where they may remain to flower and seed. For the plants which grow in the full ground, often produce more seeds than those which are in pots; but at the time when the seed-vessels begin to swell, the plants are frequently infested with green caterpillars, which, if they are not destroyed, will eat off all the seed-vessels.

If the seeds of this plant are sown on a bed of light earth in April, the plants will come up very well, and when they are not transplanted, will grow larger than those which are raised in the hot-bed, but they will not flower so early, and in cold seasons will scarce ripen their seeds. The plants may also be preserved through the winter in a green-house, where they will continue flowering most part of the year, but the second year they will not be so vigorous as the first.

The eighth sort is the Weld, which is accounted a rich commodity for dyeing; where this is cultivated, the seeds are commonly sown with Barley in the spring, and after the Barley is taken off the ground, the Weld begins to make some progress, and the next season is pulled up for use. This has been long practised, and it will be difficult to prevail on the cultivators of this plant to depart from their old customs;

but if any persons will follow the directions hereafter given, I can from experience promise them much better success.

As the Weld will grow upon very poor soil, yet the crop will be in proportion to the goodness of the land; for upon very poor ground, the plants will not rise more than a foot high, whereas upon good ground I have measured them upward of three feet, and the stalks, leaves, &c. have been in proportion; so that the better the soil is upon which it is sown, the greater will be the produce.

The best way to cultivate this plant, is to sow it without any other crop; if the ground is ready by the beginning or middle of August, that will be a good season; the land should be well ploughed and harrowed fine, but unless it is very poor, it will not require dung; when the ground is well harrowed and made fine, the seeds should be sown; one gallon of the seeds is sufficient to sow an acre of land, for they are small. If rain falls in a little time after the seeds are sown, it will bring up the plants, and in two months time they will be so far advanced as to be easily distinguished from the weeds; then they should be hoed in the like manner as Turneps, always observing to do it in dry weather, for then the weeds will soon die after they are cut up; at this time the plants may be left about six inches distance; if this is done in dry weather, and the work well performed, the plants will be clean from weeds till the spring; but as young weeds will come up in March, so if in dry weather the ground is hoed again, it may be performed at a small expence while the weeds are young, and then they will soon decay; and if after this there should be many more weeds appear, it will be proper to hoe it a third time, about the beginning of May, which will preserve the ground clean till the Weld is fit to pull. The best time to pull the Weld for use, is as soon as it begins to flower, though most people stay till the seeds are ripe, being unwilling to lose the seeds; but it is much better to sow a small piece of land with this seed, to remain for a produce of new seeds, than to let the whole stand for seed; because the plants which are permitted to stand so long will be much less worth for use, than the value of the seeds; besides, by drawing off the crop early, the ground may be sown with Wheat the same season; for the plants may be drawn up the latter end of June, when they will be in the greatest vigour, so will afford a greater quantity of the dye.

When the plants are pulled, they may be set up in small handfuls to dry in the field, and when it is dry enough, it may be tied up in bundles and housed dry, being careful to stack it loosely, that the air may pass between to prevent its fermenting.

That which is left for seeds should be pulled as soon as the seeds are ripe and set up to dry, and then beat out for use; for if the plants are left too long, the seeds will scatter. The usual price of the seed is ten shillings a bushel.

RHABBARUM. See RHEUM.

RHABBARUM MONACHORUM. See RUMEX.

RHAGADIOLUS. See LAPSANA.

RHAMNOIDES. See HIPPOPHAE.

RHAMNUS. Tourn. Inst. R. H. 593. tab. 366. Lin. Gen. Plant. 235. the Buckthorn; in French, *Nerprun*.

The CHARACTERS are,

It hath male and female flowers on different plants; these have no empalments according to some, nor petals according to others. The cover of the sexes is funnel-shaped, and cut into four parts at the top, which spread open. The male flowers have five stamina the length of the tube, terminated by small summits. The female flowers have a roundish germen, supporting a short style, crowned by a quadrifid stigma. The germen afterward becomes a roundish berry, inclosing four hard seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, which contains those plants

whose flowers have five stamina and one style; but according to his system, it should be placed in the first section of his twenty-second class; but as he has joined to this genus the Frangula, Paliurus, Alaternus, and Ziziphus of Tournefort, so to comprehend them all he has placed them in his fifth class, which had much better be kept separate.

The SPECIES are,

1. RHAMNUS (*Catharticus*) floribus axillaribus, foliis ovato-lanceolatis serratis nervosis. *Buckthorn with flowers proceeding from the sides of the branches, and oval, spear-shaped, sawed, veined leaves.* Rhamnus catharticus. C. B. P. 478. *Purging or common Buckthorn.*
2. RHAMNUS (*Minor*) floribus axillaribus, foliis ovatis acuminatis nervosis integerrimis. *Buckthorn with flowers proceeding from the sides of the branches, and oval, acute-pointed, entire leaves, having veins.* Rhamnus catharticus minor. C. B. P. 478. *Smaller purging or common Buckthorn, commonly called Dwarf Rhamnus.*
3. RHAMNUS (*Longifolia*) foliis lanceolatis, floribus axillaribus. *Buckthorn with spear-shaped leaves, and flowers growing from the sides of the stalks.* Rhamnus catharticus minor, folio longiori. Tourn. Inst. 593. *Smaller purging Buckthorn with a longer leaf.*
4. RHAMNUS (*Africana*) foliis cuneiformibus confertis perennantibus, floribus corymbosis alaribus. *Buckthorn with wedge-shaped evergreen leaves growing in clusters, and flowers growing in roundish bunches from the sides of the branches.* Rhamnus Afer, folio pruni longiore subrotundo, flore candicante, spinis longissimis. Boerh. Ind. alt. 212. *African Buckthorn with a longer roundish Plum leaf, a very white flower, and long spines.*

The first sort grows naturally in the hedges in many parts of England; it rises with a strong woody stalk to the height of twelve or fourteen feet, sending out many irregular branches; the young shoots have a smooth, grayish, brown bark, but the older branches have a darker and rougher bark, and are armed with a few short thorns. The leaves stand upon pretty long slender foot-stalks; they are of the oval spear-shape, about two inches and a half long, and one and a quarter broad, slightly sawed on their edges, of a dark green on their upper side, but of a pale or light green on their under, having a pretty strong midrib, and several veins proceeding from it, which diverge toward the sides, but meet again near the point of the leaf. The flowers come out in clusters from the side of the branches; those of the male have as many stamina as there are divisions in the petal; those of the female have a roundish germen, which afterward turns to a pulpy berry of a roundish form, inclosing four hard seeds. It flowers in June, and the berries ripen in autumn.

The berries of this are used in medicine; for with them there is a purging syrup made, called Syrupus à spina cervina, or syrup of Buckthorn; which is reckoned a good medicine to purge watery humours, and against the dropsy, jaundice, itch, and all manner of eruptions on the skin: of late years, the people who supply the market with these berries, have mixed several other sorts with them, so that when the syrup is made by persons who have not skill to distinguish the berries, it is often very bad; so that two ounces of the syrup of one shop will not purge so well as one from another, which has brought this medicine into disrepute with many persons. These berries may be easily known by examining their seeds, to see if there are four in each, and also by rubbing the juice upon white paper, which it will stain of a green colour.

From the juice of these berries is made a very fine green colour, called by the French *Verd-de-veffie*, which is much esteemed by the painters in miniature. The second sort grows naturally in the south of France; this is an humble shrub, seldom rising more than three feet high, sending out many irregular branches, covered with a dark brown bark, garnished with oval leaves ending in acute points; they are about three quarters of an inch long, and half an inch broad

R H A

broad in the widest part, which is near the base; they are of a yellowish green, and a thin consistence, having several veins diverging from the midrib toward the sides, which converge again toward the point. The flowers come out upon small curfons or spurs on the side of the branches, each standing upon a separate short foot-stalk; they are of a yellowish herbaceous colour, having short swelling tubes, and are cut into five acute segments at the top, which spread open; they appear in June, but are not succeeded by berries here.

Mr. Du Hamel de Monceaux, of the Royal Academy of Sciences at Paris, says, that the fruit of this species gathered green is the Grain d'Avignon, or Avignon berries, which are used in dyeing of yellow; but I have been assured by a gentleman of skill, who resided long in the south of France, that the Avignon berries were the fruit of the narrow-leaved Alaternus; and in order to be better satisfied of the truth, I gathered a quantity of the berries of the narrow-leaved Alaternus before they were full ripe, and carried them to two eminent dealers in this commodity, and asked them if they knew what these berries were; they both assured me, after making trial of them, that they were Avignon berries, and if I had a large quantity of them, they would purchase them all: therefore, as the Alaternus before-mentioned is one of the most common shrubs in the south of France, from whence the Avignon berries are brought, we may suppose Mr du Hamel has been ill informed.

The third sort grows naturally in Spain and Italy; this grows to a larger size than the second, but not so high as the first. The branches are stronger, and are armed with a few long spines; the leaves are like those of the wild Plum, but are a little longer and narrower; the flowers are small, of a yellowish colour, and are produced from the side of the branches; these appear in June, but are not succeeded by berries in this country.

The first sort is so common in the hedges in many parts of England, that it is seldom cultivated in gardens; this rises easily from seeds, if they are sown in autumn soon after the berries are ripe; but, if they are kept out of the ground till spring, the plants will not come up till the year after; these will require no particular treatment, but may be managed in the same way as young Crabs, or any other hardy deciduous tree; it may also be propagated by cuttings or layers. If the young shoots are layed in autumn, they will put out roots by the following autumn, when they may be taken off from the plants, and either planted in a nursery to remain there to get strength for a year or two, or they may be planted where they are designed to remain. This is not so proper for hedges as the Hawthorn or Crab, so those should be preferred to it. The second and third sorts are preserved in botanic gardens for the sake of variety; but as they are not beautiful, few persons cultivate them here, especially as these do not produce fruit in England. They may be propagated either by laying down the young branches in autumn, or by planting the cuttings in the spring, before the buds begin to swell. These will put out roots in the same manner as the common sort, and may be treated in the same way, for they are both hardy plants, and will thrive in the open air. The fourth sort grows naturally at the Cape of Good Hope, so is too tender to thrive in the open air in England; but if it is placed in a common green-house with Myrtles, Olives, and the hardier kinds of exotic plants in winter, and removed to the open air in summer, it will thrive very well. This rises with a shrubby stalk to the height of four or five feet, sending out many side branches, which, when young, are covered with a green bark, but as they advance, the bark changes to a dark brown; they are armed with a few long slender thorns, and garnished with wedge-shaped leaves, which come out in clusters at each joint, four, five, or six rising from the same point, which differ in size, the largest being about an inch long, and three quarters broad, and the smallest about

R H E

half as large; they are of a deep green, and continue all the year; their points are broad and rounded, growing narrower to their base, sitting close to the branches. The flowers are produced on the side of the branches at each joint; they are collected into roundish bunches, standing upon foot-stalks an inch long; they are white, and have short tubes; their upper part is cut into five acute segments, which spread open in form of a star. These appear in June, at which time the whole shrub seems covered with flowers, so as to make a fine appearance; and as the leaves continue green all the year, it deserves a place where there is a conveniency to shelter them in winter.

This sort has not as yet produced seeds in England, but it may be easily propagated by cuttings, which should be planted in pots filled with loamy earth the beginning of April. The pots should be plunged into a moderate hot-bed, and the cuttings should be shaded from the sun in the heat of the day; they must also be sprinkled with water two or three times a week, according as the earth in the pot dries, but they must by no means have too much wet. These cuttings will put out roots in two months, and soon after will begin to make shoots at the top; then they must have a large share of air admitted to them, and gradually inured to bear the open air, into which they should be soon after removed; and when they are well hardened, they may be shaken out of the pots, and separated, being careful to preserve a ball of earth to each, and plant them into single pots filled with soft loamy earth, placing them in the shade till they have taken new root; then they may be removed into a sheltered situation, where they may remain till the frost comes on in autumn, at which time they must be housed, and treated in the same way as the other hardier kinds of green-house plants.

RHEUM. Lin. Gen. Plant. 454. Rhabarbarum. Tourn. Inst. R. H. 89. tab. 18. The Rhubarb.

The CHARACTERS are,

The flower has no empalement; it hath one petal, which is narrow at the base, and imperious. The brim is cut into six parts, which are obtuse and alternately smaller; it hath nine hair-like stamina inserted in the petal, and is of the same length, terminated by oblong twin summits which are obtuse, and a short three-cornered germen, with scarce any style, crowned by three feathered stigmas which are reflexed. The germen afterward becomes a large three-cornered seed, with acute membranaceous borders.

This genus of plants is ranged in the second section of Linnæus's ninth class, which contains those plants whose flowers have nine stamina or stigmas, and three styles.

The SPECIES are,

1. RHEUM (*Rhaponticum*) foliis cordatis glabris spicis obtusis. Rhubarb with smooth heart-shaped leaves, and obtuse spikes of flowers. Rhaponticum. Prof. Alp. Exot. 187. The Rhapontick, commonly called English Rhubarb.
2. RHEUM (*Undulatum*) foliis subvillosis undulatis petiolis æqualibus. Lin. Diss. 1. tab. 1. Sp. Plant. 372. Rhubarb with hairy waved leaves, having equal foot-stalks. Rhabarbarum folio longiori hirsuto crispo, florum thyrsis longiori & tenuiori. Amman. Ruth. 9. Rhubarb with a longer hairy curled leaf, and a longer and slender spike of flowers.
3. RHEUM (*Compactum*) foliis cordatis glabris, marginibus sinuatis, spicis erectis compactis. Tab. 218. Rhubarb with heart-shaped smooth leaves, which are sinuated on their borders, and erect compact spikes of flowers.
4. RHEUM (*Palmatum*) foliis palmatis acuminatis. Lin. Sp. 531. Rhubarb with pointed hand-shaped leaves.
5. RHEUM (*Ribes*) foliis granulatis, petiolis æqualibus. Lin. Sp. Plant. 372. Rhubarb with granulated leaves having equal foot-stalks. Lapathum Orientale asperum & verrucosum folio, Ribes Arabium dictum. Hort. Elth. 191. tab. 158. Eastern Dock with a rough warted leaf, called by the Arabians Ribes.

The first sort grows naturally near the Pontic Sea, but has been long an inhabitant of the English gardens. When the seeds were first brought to Europe, they were supposed to be of the true Rhubarb, but upon

Upon making trial of the roots, they were found to be greatly inferior to those of the true Rhubarb, and upon farther trials and examination, it was found to be the Rhapontick of Prosper Alpinus, commonly called Pontick Rhubarb. This hath a large thick root, which divides into many strong fleshy fangs, running deep in the ground; the outside is of a reddish brown colour, and the inside yellow, from which arise several leaves, in number according to the size of the root; these come up folded in the spring, and afterward expand themselves; they are smooth, of a roundish heart-shape, having very thick foot-stalks of a reddish colour, which are a little channelled on their lower part, but flat at the top. When the plant grows in rich land, the foot-stalks of the leaves are near two feet long, and thicker than a man's thumb; the leaves also are often two feet long, and as much in breadth, having several strong longitudinal veins running from the foot-stalk to the borders, of a deep green, and are waved on their edges, having an acid taste, but particularly the foot-stalks, which are now frequently used for making tarts. From between the leaves arise the flower-stem, which is of a purple colour, garnished with one leaf at each joint, of the same shape with those below, but smaller, and sit close to the stalk. The stalks grow from two to three feet high, according to the strength of the ground, and are terminated by thick, close, obtuse spikes of white flowers, which appear the beginning of June, and are succeeded by large, triangular, brown seeds, having a border or wing at each angle, which ripen in August.

The seeds of the second sort were sent me from Leyden by the late Dr. Boerhaave, by the title of *Rhabarbarum Chinense verum*, or true China Rhubarb, which succeeded in the Chelsea Garden. The root of this sort divides into a number of thick fibres, which run deeper into the ground than those of the first, and are of a deeper yellow within. The leaves appear much earlier in the spring; the foot-stalks are not so much channelled on their under side, and are plain on their upper, not so red nor so thick as those. The leaves are longer, running more to a point, and are much waved on their edges, a little hairy on their upper side, and have many strong veins or ribs on their under. The flower-stem is of a pale brownish colour, rising about four feet high, dividing into several loose panicles or bunches of white flowers, which appear in May, and are succeeded by triangular seeds like those of the first sort, which ripen earlier in the season.

The seeds of the third sort were sent me from Petersburg, for the true Tartarian Rhubarb. The roots of this sort are large, and divide into many fangs; they are yellow within; the leaves appear early in the spring; the foot-stalks of these are of a pale green, and almost as large as those of the first sort; they have scarce any channels, and flat on their upper side; the leaves are smooth, heart-shaped, and do not run out to so great length in a point as those of the second, but are longer than those of the first; they are very broad toward their base, and have very large pale green ribs on their under side, a little waved on their edges, having a sharp acid flavour. The flower-stalk is of a pale green; it rises five or six feet high, and are as large as a common walking cane, garnished at each joint by one leaf of the same shape with those below, but smaller, sitting close to the stalk; the upper part of the stalk divides into small branches, each sustaining a panicle or spike of white flowers standing erect, which appear the latter end of May, and are succeeded by large triangular bordered seeds, like those of the first sort.

The roots of this last approach nearer to those of the foreign Rhubarb than either of the other, both in shape and quality; and as these seeds which were sent to Petersburg, were gathered from the plants growing on the spot where the Rhubarb is taken up, so there is little reason to doubt of its being the true sort, though the roots which have grown in Eng-

land have not been equal in quality with those of the foreign; but this may have been occasioned for want of age, or by being taken out of the ground at an improper season, therefore farther trials may improve it; and as the plants produce great plenty of seeds here, so they may be propagated with great ease. Dr. Linnæus seemed first to think the second sort was the true Rhubarb, but the roots of that which have grown here are very little better than those of the Rhapontick, and I have reason to doubt if it is not a variety of it; for it is certain, these plants when growing near each other, are impregnated by each other's farina; for from the seeds of the Rhapontick, which grew close to the second sort, I had a mixture of plants of both sorts produced, though the plant of the second sort did not produce any seeds, for the stalk decayed soon after the flowers faded; and the seeds of the Rhapontick were gathered by myself from one plant, and were sown in his Grace the Duke of Bedford's garden at Wooburn Abbey, where there had not been any of these plants before growing, so that there could be no mixture of seeds, and yet a third part of the plants proved to be of the second sort.

It has been learnedly controverted by the botanists, whether the Rhapontick of the ancients, and the Rhubarb of the moderns, is one and the same plant, some affirming, and others denying that there is any agreement; the reasonings on both sides may be seen in the Appendix to the second volume of John Bauhin's History of Plants.

The seeds of the fourth sort have been lately brought to England, from which many plants have been raised; these greatly differ in the form of their leaves from all the other species, for they are deeply cut into many acute segments, which spread open in form of a hand; and I am informed by a skilful botanist, who has seen this sort in flower, that it should be placed in the genus of *Rumex*, for there are but six stamina in each flower; but as the plant in the Chelsea Garden has not as yet flowered, nor have I seen any plants in that state, so I cannot take upon me to determine this.

However, I find the celebrated Linnæus now supposes this to be the true Rhubarb, which farther experiments must settle.

The fifth sort grows naturally on Mount Libanus, and other mountainous parts of Syria. This hath a thick fleshy root, which runs pretty deep in the ground, from which arise several leaves in the spring, which come up folded together, and afterward expand; they have very short foot-stalks, so spread near the ground; but during the spring, their borders are erect, and form a sort of hood having several folds, and are curled and waved on their edges; they are of a purplish green, and have purple veins and borders; their surface appears studded with rough protuberances, and when the leaves are fully expanded in summer, they are a foot long, and above two feet broad; their under side is paler than the upper, and their borders appear fringed. I have not seen this plant in flower, but the seeds of it were brought from Mount Libanus, by the Right Rev. Dr. Pocock, the late Bishop of Ossory; these were larger than those of the other species, and covered with a succulent pulp, of a deep red colour, and very astringent taste; this succulent covering may have occasioned its being taken for a berry, by many of the old writers; the shape of the seed is like that of the other species.

These plants are all propagated by seeds, which should be sown in autumn soon after they are ripe, and then the plants will come up the following spring; but if they are kept out of the ground till spring, the plants seldom come up till the next spring, so that a whole year will be lost. The seeds should be sown where the plants are designed to remain; for as their roots are large and fleshy, so when they are transplanted, they do not recover their removal soon; nor will the roots of those plants which are transplanted, ever grow so large and fair, as those which remain where they

they were sown. When the plants appear in the spring, the ground should be hoed over to cut up the weeds; and where the plants are too close, some should be cut up, to allow room for the others to grow, in the same manner as is practised for Carrots and Parsneps, leaving them at the first time of hoeing six or eight inches asunder, for fear of accidents; but at the second time of hoeing they may be separated to a foot and a half distance, or more. After this, the plants will require no other culture but to keep them clean from weeds, so that as soon as the weeds appear, if the ground is scuffled over with a Dutch hoe in dry weather, it may be done for a small expence, and thereby the ground will be kept clean. If this is begun early in the spring before the weeds are large, they will soon die, and by repeating it two or three times at proper intervals, during the spring, the ground will be made clean; and when the plants spread out their leaves to cover the ground, they will prevent the growth of weeds.

In autumn the leaves of these plants decay, then the ground should be made clean, and in the spring, before the plants begin to put up their new leaves, the ground should be either digged between the plants, or be hoed and made clean again; the second year after the plants come up, many of the strongest will produce flowers and seeds, but the third year most of them will flower. The seeds of these should be carefully gathered when ripe, and not permitted to scatter, lest they should grow to injure the old plants. The roots of these plants will remain many years without decaying; and I am informed, that the old roots of the true Rhubarb are much preferable to the young ones. They delight in a rich soil, not too dry, nor over moist; and where there is a good depth for their roots to run down in such land, their leaves will be very large, and their roots will grow to a great size.

The first sort is now frequently cultivated in gardens for the foot-stalks of their leaves, which are peeled and made into tarts in the spring: it is also kept in gardens, to supply the shops with the roots, which are used in medicine.

The true Rhubarb is now sown in many gardens, and may probably succeed so well here in time, as that a sufficient quantity of that valuable drug may be raised, to supply our consumption.

RHEXIA. Gron. Flor. Virg. 41. Lin. Gen. Plant. 423.

The CHARACTERS are,

The empalement of the flower is permanent, oblong, tubulous, and of one leaf, swelling below, but divided into four parts at the brim. The flower has four roundish petals inserted in the empalement, which spread open. It hath eight slender stamina which are inserted in the empalement, terminated by declining furrowed summits, which are narrow, obtuse, and moveable. It has a roundish germen, supporting a declining style the length of the stamina, crowned by a thick oblong stigma. The germen afterward becomes a roundish capsule with four cells in the swollen empalement, opening with four valves, and filled with roundish seeds.

This genus of plants is ranged in the first section of Linnæus's eighth class, which includes those plants whose flowers have eight stamina and one style.

The SPECIES are,

1. **RHEXIA** (*Virginica*) foliis sessilibus serratis calycibus glabris. Flor. Virg. 41. *Rhexia with smooth empalements, and sawed leaves sitting close to the stalks. Lysimachia non papposa Virginiana, tuberariae foliis hirsutis, flore tetrapetalo rubello. Pluk. Phyt. tab. 202. f. 8. Virginian Loofstrife without down, having a hairy leaf like Tuberaria, with a red flower having four petals.*
2. **RHEXIA** (*Mariana*) foliis ciliatis. Lin. Sp. Plant. 346. *Rhexia with fine hairy leaves. Lysimachia non papposa, terræ Marianæ, leptoneuros, flore trepetalo rubello, folio & caule hirsutis ferruginea hispida. Pluk. Phyt. 428. f. 1. Loofstrife of Maryland having no down, but a reddish flower with four petals, and a leaf and stalk covered with iron-coloured hairs.*

The first sort was discovered by Mr. Banister in Vir-

ginia, from whence he sent the seeds to England; which succeeded in several gardens. This rises with an erect stalk near a foot and a half high, which is four-cornered and hairy, garnished with spear-shaped hairy leaves about two inches long, and half an inch broad, which are entire, and placed opposite. The stalk has two foot-stalks coming out from the side opposite at the upper joint, and is terminated by two other; these each sustain two or three red flowers with heart-shaped petals, which spread open in form of a cross. These appear in June, but I have not seen any seeds produced here.

The second sort grows naturally in Maryland, from whence I received the seeds. This sends up an erect stalk about ten inches high, garnished with spear-shaped leaves about an inch long, and a third part of an inch broad, set on by pairs; and from every joint of the stalk comes out two short shoots opposite, garnished with small leaves of the same shape as the other; the whole plant is thick, set with stinging iron-coloured hairs. The stalk divides at the top into two foot-stalks, spreading from each other, having one reddish flower on each; these have four heart-shaped petals, which spread open like the other. It flowers about the same time as the first, but seldom produces seeds here. These plants are propagated by seeds, which must be procured from the places where they grow naturally. If the seeds arrive before the spring, and are sown soon after they arrive in pots filled with good fresh earth, and placed under a garden frame to guard them from frost, the plants will come up the following spring; but when the seeds are sown in the spring, the plants rarely come up the first year. When the plants come up and are fit to remove, part of them should be planted in an east border, where they may have only the morning sun, and the others may be planted into pots, that they may be sheltered under a frame in winter, for they are often destroyed by severe frost, though they will live abroad in the common winters very well; the second year the plants will flower, and with care they may be continued three or four years.

RHINANTHUS. Lin. Gen. Plant. 658. Pedicularis species. Tourn. Inst. 171. Elephas. Tourn. Cor. 48. tab. 482. Rattle, or Lousewort.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is roundish, compressed, and blown up. It hath one ringent petal, with a cylindrical tube the length of the empalement, compressed at the base, but opening at the top. The upper lip is hooded, compressed, and indented at the point; the lower lip is plain, spreading, and cut into three obtuse segments at the point. It has four stamina, which are shut up in the upper lip, two of which are shorter than the other, terminated by hairy incumbent summits, and an oval compressed germen supporting a slender style, situated with the stamina, crowned by an inflexed obtuse stigma. The germen afterward turns to an oval compressed capsule with two cells, opening on the side, and filled with compressed seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, which includes those plants whose flowers have two long and two shorter stamina and the seeds are lodged in a capsule.

1. **RHINANTHUS** (*Crista galli*) corollarum labio superiore compresso, brevior. Flor. Lap. 248. *Rhinanthus with a shorter compressed upper lip. Pedicularis pratensis lutea, vel crista galli. C. B. P. 163. Yellow Meadow Lousewort, yellow Rattle, or Cock's-comb.*
2. **RHINANTHUS** (*Orientalis*) corollarum labio superiore subulato incurvo. Lin. Sp. Plant. 603. *Rhinanthus with an awl-shaped incurved upper lip. Elephas Orientalis, flore magno, proboscide incurvâ. Tourn. Cor. 48. Eastern Elephant's-head, with a large flower and an incurved trunk.*
3. **RHINANTHUS** (*Elephas*) corollarum labio superiore subulato erecto. Prod. Leyd. 298. *Rhinanthus with an erect awl-shaped upper lip. Elephas Italica, flore magno, proboscide furrectâ. Tourn. Cor. 48. Italian Elephant's-head, with a large flower and an erect trunk.*

The first sort is a common weed in most of the low pastures and meadows in many parts of England where it is one of the most troublesome weeds among the Grass, spreading itself over the whole ground, so that in many of the water meadows, there is more of this plant than Grass. It is an annual plant, which flowers the latter end of May, so that the seeds ripen by the time the Grass of these meadows is mowed, and the seeds scatter and fill the ground with young plants the following spring; therefore, in order to destroy it, the Grass should be cut as soon as the flowers of this plant appear.

It is well known, so requires no description; and as it is never cultivated, so it is mentioned chiefly to introduce the others; but here I must observe, that the Dutch carry on a trade with the seeds and seed-vessels of one species of this genus to Germany, whose seed-vessels appear very like those of this first sort, they call it Semen Savadillos; the use of it is to kill vermin of every sort, especially bugs; they boil a quantity of the seeds and capsules in common water, with which they wash their wainscots, bedsteads, &c. where any of these insects are lodged, and it effectually destroys them.

The second sort was discovered by Dr. Tournefort on the sides of the Black Sea, growing in a fat soil and shady situation. The flower being shaped like an Elephant's-head, induced Fabius Columna to give the title of Elephas to the third species, which he found growing naturally in the kingdom of Naples, and Tournefort after him established the genus with that title. The stalks of this rise a foot and a half high; they are hollow, four-cornered, and hairy, garnished with leaves placed opposite, having short foot-stalks; they are about two inches long, and half an inch broad, crenated on their edges, hairy, and veined. The upper part of the stalk is garnished with flowers growing opposite from the wings of the leaves; these have curved tubes, which divide into two lips; the under lip is an inch long, broad, and cut into three obtuse parts, the middle segment being the broadest; the upper lip is like a helmet, and is longer than the lower. The flower is yellow, with a spot of fillemort on the lower lip, and the upper lip has two red spots on the top; the flowers have an agreeable scent.

The third sort grows naturally in the kingdom of Naples; this is much like the former sort, but the proboëis of the flower is erect, and the lower lip has no spot.

These plants despise culture, so are with great difficulty kept in gardens; they are biennial, so are only propagated by seeds; these should be sown soon after they are ripe, otherwise they will not succeed, nor will the plants bear removing, so they should be sown where they are to remain, which should be in a moist rich soil and a shady situation: when the plants come up, they must be thinned and kept clear from weeds, which is all the culture they require. If the seeds of these plants are permitted to scatter, the plants will come up better than those which are sown by hand, but they thrive best amongst Grass.

RHIZOPHORA. Lin. Gen. Plant. 524. Mangles. Plum. Nov. Gen. 13. tab. 15. This is called Mangrove by the inhabitants of the West-Indies; there are several species of this kind, which grow in salt-water rivers both in the East and West-Indies, but as they will not grow upon land, it is needless to enumerate them here.

RHODIOLA. Lin. Gen. Plant. 997. Anacamperos. Tourn. Inst. R. H. 264. Rose-root.

The CHARACTERS are,

It hath male and female flowers in different plants; the male flowers have an empalement of one leaf, which is cut into four or five segments almost to the bottom; they have four obtuse petals, which are much longer than the empalement, and four nectariums, which are erect and shorter than the empalement, with eight awl-shaped stamina which are longer than the petals, terminated by obtuse summits. They have four oblong acute germen without style or stigma, so are abortive. The female flowers have the same

empalement as the male; they have four obtuse permanent petals equal with the empalement, and four nectariums like the male; they have four oblong acute-pointed germen sitting upon an erect style, crowned by obtuse stigmas. The germen afterward become four horned capsules, compressed on their inner side, filled with roundish seeds.

This genus of plants is ranged in the seventh section of Linnæus's twenty-second class, which contains those plants whose male and female flowers are upon different plants, and the male flowers have eight stamina.

The SPECIES are,

1. **RHODIOLA (Rosea)** staminibus corollâ duplo longioribus. *Rose-root with stamina twice as long as the petals. Anacamperos radice rosam spirante major. Tourn. Inst. R. H. 264. Greater Orpine with a Rose-scented root.*
2. **RHODIOLA (Minor)** staminibus corolla ferè æquantibus. *Rose-root with stamina scarcely equalling the length of the petals. Anacamperos radice rosam spirante minor. Tourn. Inst. R. H. 264. Smaller Orpine with a Rose-scented root.*

The first sort grows naturally in the clefts of the rocks and rugged parts of the mountains of Wales, Yorkshire, and Westmoreland. This has a very thick fleshy root, which, when bruised or cut, sends out an odour like Roses; it has many heads, from whence in the spring come out thick succulent stalks like those of Orpine, about nine inches long, closely garnished with thick succulent leaves of a gray colour, which are an inch long, and half an inch broad, indented on their edges toward the top, and are placed alternately on every side the stalk. The stalk is terminated by a cluster of yellowish herbaceous flowers, which appear early in May; the male flowers have stamina twice the length of the petals. They have a very agreeable scent, but are not of long continuance.

The second sort grows naturally on the Alps; the roots of this are smaller than those of the other sort, the stalks are small, and not above five inches long; the leaves are small, but shaped like those of the other sort, and end with a purple point; the petals of the flowers are purplish, and the stamina are but little longer than the petals. This flowers later than the other sort. I have cultivated both these plants in the same soil above thirty years, and have never found either of them vary.

These plants are preserved in the gardens of the curious, for the sake of variety; they are easily propagated, either by cuttings or parting of the roots. If by cuttings, they should be planted the beginning of April, soon after they come out from the head; if these are planted in a shady border, and covered close down with a glass, keeping them dry, they will put out roots in about six weeks; but the cuttings should be laid in a dry room at least a week before they are planted, that the wounds may be dried before they are planted, otherwise they are subject to rot.

If they are propagated by parting of the roots, that should be performed in the beginning of September, at which time their stalks begin to decay; and if the fleshy parts of the roots are cut or broken, they should be laid to dry a few days before they are planted, for the same reason as the cuttings. These plants require a shady situation and a dry undunged soil, in which they will continue many years.

RHODODENDRON. Lin. Gen. Plant. 484. Chamærhododendros. Tourn. Inst. R. H. 604. tab. 373. Dwarf Rose-bay.

The CHARACTERS are,

The flower has a permanent empalement cut into five segments; the flower hath one wheel funnel-shaped petal, spreading open at the brim; it has ten slender stamina which decline, and are the length of the petals, terminated by oval summits, and a five-cornered germen, supporting a slender style the length of the petal, crowned by an obtuse stigma. The germen afterward becomes an oval capsule with five cells, filled with small seeds.

This

R H O

This genus of plants is ranged in the first section of Linnæus's tenth class, which contains those plants whose flowers have ten stamina and one style.

The SPECIES are,

1. RHODODENDRON (*Hirsutum*) foliis ciliatis nudis, corollis infundibuliformibus. Lin. Sp. Plant. 292. *Rose-bay with naked hairy leaves, and funnel-shaped petals.* Chamærhododendros Alpina, villosa. Tourn. Inst. R. H. 604. *Hairy Alpine Dwarf Rose-bay.*
2. RHODODENDRON (*Ferrugineum*) foliis glabris, subtus leprosis, corollis infundibuliformibus. Lin. Sp. Plant. 392. *Rose-bay with smooth leaves which are hoary on their under side, and funnel-shaped petals.* Chamærhododendros Alpina glabra. Tourn. Inst. R. H. 604. *Smooth Alpine Dwarf Rose-bay.*

The first sort grows naturally on the Alps, and also upon several mountains in Italy. This is a low shrub, which seldom rises two feet high, sending out many short ligneous branches, covered with a light brown bark, and garnished closely with oval spear-shaped leaves about half an inch long, and a quarter of an inch broad, sitting pretty close to the branches; they are entire, and have a great number of fine iron-coloured hairs on their edges and under side. The flowers are produced in bunches at the end of the branches; they have one funnel-shaped petal; the tube is about half an inch long; the brim is cut into five obtuse segments, which spread half open; they are of a pale red colour, and have ten stamina in each, which are the length of the tube; after the flowers are past, the germen in the center turns to an oval capsule with five cells, filled with small seeds. It flowers in May, and the seeds ripen in August.

The second sort grows naturally on the Alps and Apennines; this rises with a shrubby stalk near three feet high, sending out many irregular branches, covered with a purplish bark, and closely garnished with smooth spear-shaped leaves an inch and a half long, and half an inch broad in the middle; they are entire, and their borders are reflexed backward; the upper side is of a light lucid green, and their under side of an iron colour; they are placed all round the branches without any order. The flowers are produced in round bunches at the end of the branches; they are funnel-shaped, having short tubes, which are cut into five obtuse segments at the brim, which spread a little open; they are of a pale Rose colour, and make a good appearance. This sort flowers in June, but does not ripen seeds here.

There are some other species of this genus which grow naturally in the eastern countries, and others are natives of America, but the two sorts here mentioned are all I have seen in the English gardens; and these are difficult to propagate and preserve in gardens, for they grow naturally upon barren rocky soils and in cold situations, where they are covered with snow great part of the winter; so that when they are planted in better ground, they do not thrive, and for want of their usual covering of snow in winter, they are frequently killed by frost; but could these plants be tamed, and propagated in plenty, they would be great ornaments to the gardens.

They are propagated by seeds, but these are so very small, that if they are covered deep, they will not grow. The seeds should be sown as soon as possible after they are ripe, either in shady borders or pots filled with fresh gentle loamy earth, and very lightly covered with a little fine earth; then the pots should be plunged up to their rims in a shady border, and in hard frost they should be covered with bell or hand-glasses, taking them off in mild weather. If these seeds are sown early in autumn, the plants will come up the following spring; these must be kept shaded from the sun, especially the first summer, and duly refreshed with water, and in autumn following, they may be transplanted to a shady situation and on a loamy soil, covering the ground about their roots with Moss, which will guard them from frost in winter, and keep the ground moist in summer.

R H U

RHUS. Tourn. Inst. R. H. 611. tab. 381. Lin. Gen. Plant. 331. [*ῥῖς* takes its name from *ῥίω* to flow, because it stops dysenterial fluxes of the bowels.] Sumach.

The CHARACTERS are,

The empalement of the flower is permanent, erect, and cut into five parts. The flower has five oval, erect, spreading petals, and five short stamina terminated by small summits, shorter than the petals; it has a roundish germen as large as the petals, with scarce any style, crowned by three small stigmas. The germen afterward becomes a roundish hairy berry, inclosing a single hard seed of the same form.

This genus of plants is ranged in the third section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and three styles.

The SPECIES are,

1. RHUS (*Coriaria*) foliis pinnatis obtusiusculè ferratis, ovalibus subtus villosis. Lin. Sp. Plant. 379. *Sumach with winged leaves which are obtusely sawed, oval, and hairy on their under side.* Rhus folio ulmi. C. B. P. 414. *Elm-leaved Sumach.*
2. RHUS (*Typhinum*) foliis pinnatis lanceolatis, argute ferratis subtus tomentosis. Amœn. Acad. 4. p. 311. *Sumach with spear-shaped winged leaves which are sharply sawed, and woolly on their under side.* Rhus Virginianum. C. B. P. App. 517. *Virginian Sumach.*
3. RHUS (*Glabrum*) foliis pinnatis ferratis lanceolatis utrinque glabris. *Sumach with winged leaves which are spear-shaped, and smooth on both sides.* Rhus Virginicum, paniculâ sparsâ, ramis patulis glabris. Hort. Elth. 323. *Virginian Sumach with a loose panicle, and smooth spreading branches.*
4. RHUS (*Carolinianum*) foliis pinnatis ferratis lanceolatis, subtus incanis, paniculâ compactâ. *Sumach with sawed, spear-shaped, winged leaves which are hoary on their under side, with a compact panicle.* Rhus Carolinianum paniculâ speciosâ coccineâ. Catesb. Hist. Carol. *Carolina Sumach having a beautiful scarlet panicle.*
5. RHUS (*Canadense*) foliis pinnatis, obsolete ferratis, lanceolatis, utrinque glabris, paniculâ compositâ. *Sumach with winged spear-shaped leaves which are slightly sawed, and a compound panicle.* Rhus Canadense folio longiori utrinque glabro. Tourn. Inst. R. H. 611. *Canada Sumach, with a longer leaf which is smooth on both sides.*
6. RHUS (*Copallinum*) foliis pinnatis integerrimis, petiolo membranaceo articulato. Flor. Leyd. Prod. 24. *Sumach with entire winged leaves, and a jointed membranaceous foot-stalk.* Rhus angustifolium. C. B. P. 414. *Narrow-leaved Sumach.*
7. RHUS (*Chinense*) foliis pinnatis, foliolis ovatis, obtusè ferratis, petiolo membranaceo villosis. *Sumach with winged stalks, oval lobes which are bluntly sawed, and a hairy foot-stalk having jointed membranes or wings.* Rhus Sinarum lactescens, costâ foliorum alata. Pluk. Am. 183. *China milky Sumach, with winged membranes to the leaves.*
8. RHUS (*Incanum*) foliis ternatis, foliolis ovatis subtus tomentosis. *Three-leaved Sumach, with oval leaves which are downy on their under side.* Rhus Africanum majus folio subrotundo integro, molli & incano. Pluk. Phyt. tab. 219. fig. 8. *Greater, three-leaved, African Sumach, with a rounder entire leaf which is soft and hoary.*
9. RHUS (*Tomentosum*) foliis ternatis foliolis subpetiolatis, rhombeis angulatis, subtus tomentosis. Lin. Sp. Plant. 266. *Three-leaved Sumach with angular rhomboid lobes having foot-stalks, and downy on their under side.* Rhus Africanum trifoliatum majus, foliis obtusis & incisus hirsutis pubescentibus. Pluk. Phyt. tab. 219. fig. 7. *Greater, African, three-leaved Sumach, with obtuse cut leaves which are covered with soft hairs.*
10. RHUS (*Lucidum*) foliis ternatis, foliolis sessilibus cuneiformibus lævibus. Vir. Cliff. 25. *Three-leaved Sumach whose lobes are smooth, wedge-shaped, and sit close to the stalk.* Rhus Africanum, trifoliatum minus glabrum, splendente folio, subrotundo integro. Pluk. Phyt. 219. fig. 9. *Three-leaved African Sumach, with a smooth, shining, roundish, entire leaf which is small.*

11. RHUS

11. *Rhus (Africanum)* foliis ternatis, foliolis ovatis nervosis, marginibus sæpius dentatis, utrinque viridibus. *Sumach with trifoliate leaves having oval veined lobes which are generally indented on their edges, and green on both sides.* *Rhus Africanum*, trifoliatum majus glabrum, splendente utrinque folio subrotundo medio quandoque crenato. Boerh. Ind. alt. 2. p. 229. *Greater, African, three-leaved Sumach, with smooth roundish leaves on both sides, which are sometimes crenated in the middle.*
12. *Rhus (Argenteum)* foliis ternatis, foliolis petiolatis lineari-lanceolatis integerrimis subtus tomentosis. Hort. Cliff. 111. *Sumach with trifoliate leaves, whose lobes stand upon foot-stalks, are linear, spear-shaped, entire, and downy on their under side.* *Rhus Africanum trifoliatum majus*, foliis subtus argenteis acutis & margine incis. Pluk. Phyt. tab. 219. fig. 6. *Greater African three-leaved Sumach, with leaves which are silvery on their under side, and cut on their edges.*
13. *Rhus (Radelijawel)* foliis ternatis, foliolis ovatis acuminatis integerrimis, petiolatis, floribus paniculatis terminalibus. *Three-leaved Sumach, with oval acute-pointed lobes which are entire, upon foot-stalks growing in panicles which terminate the branches.* *Phaseolus arborescens Zeylanicus monocarpus*, Radelijawel. Herm. Mus. Zeyl. 39. *Tree Kidney-bean of Ceylon with a single fruit, called Radelijawel.*
14. *Rhus (Rigidum)* foliis ternatis linearibus integris rigidis glabris. *Sumach with three linear, entire, rigid, smooth leaves.*
15. *Rhus (Cotinus)* foliis simplicibus obovatis. Lin. Sp. Plant. 267. *Sumach with single, obverse, oval leaves.* *Cotinus Coriaria*. Dod. Pemp. 780. *Venice Sumach, or Coccygria.*

The first sort of Sumach grows naturally in Italy, Spain, and Turkey; the branches of this tree are used instead of Oak bark for tanning of leather, and I have been informed that the Turkey leather is all tanned with this shrub. It hath a strong ligneous stalk which divides into many irregular branches, which rise to the height of eight or ten feet; the bark is hairy, and of an herbaceous brown colour while young; the leaves are winged, and composed of seven or eight pair of lobes terminated by an odd one; the lobes are about two inches long, and half an inch wide in the middle; they are bluntly sawed on their edges, and hairy on their under side, of a yellowish green colour; they are placed alternately on the branches; the flowers grow in loose panicles at the end of the branches, which are of a whitish herbaceous colour, each panicle being composed of several close spikes of flowers sitting close to the foot-stalks; these appear in July, but are not succeeded by seeds in England. The leaves and seeds of this sort are used in medicine, and are esteemed very restraining and stiptick, and good for all kinds of fluxes and hæmorrhages; used both inwardly and outwardly, they resist putrefaction, and stop gangrenes and mortifications.

The second sort grows naturally in almost every part of North America; this hath a woody stem, from which are sent out many irregular branches, which are generally crooked and deformed. The young branches are covered with a soft velvet like down, resembling greatly that of a young stag's-horn both in colour and texture, from whence the common people have given it the appellation of Stag's-horn; the leaves are winged, composed of six or seven pair of oblong lobes, terminated by an odd one, ending in acute points; they are entire, and hairy on their under side, as is also the midrib. The flowers are produced in close tufts at the end of the branches, which are succeeded by seeds inclosed in purple, woolly, succulent covers, so that the bunches are of a beautiful purple colour in autumn, and the leaves before they fall, change also to a purplish colour first, and before they fall, to a feuilemort. This is used for tanning of leather in America, and the roots are often prescribed in medicine in the countries where the plant grows naturally.

The third sort grows naturally in many parts of North America; this is commonly titled by the gardeners New England Sumach. The stem of this sort is stronger, and rises higher than that of the former; the branches spread more horizontally; they are not quite so downy as those of the last, and the down is of a brownish colour; the leaves are composed of many more pair of lobes, which are smooth on both sides; the flowers are disposed in loose panicles, which are of an herbaceous colour; they appear about the same time with those of the former, but are not succeeded by seeds in England.

The fourth sort grows naturally in Carolina; the seeds of this were brought from thence by the late Mr. Catesby, who has given a figure of the plant in his Natural History of Carolina. This is by the gardeners called the scarlet Carolina Sumach; it rises commonly to the height of seven or eight feet, and divides into many irregular branches, which are smooth, of a purple colour, and pounced over with a grayish powder, as are also the foot-stalks of the leaves, which are of a purplish colour. The leaves are composed of seven or eight pair of lobes terminated by an odd one; these are not always placed exactly opposite on the midrib, but are sometimes alternate; they are three or four inches long, and almost one broad in the middle, ending in acute points, and are sawed on their edges. The upper side of the lobes are of a dark green, and their under hoary, but smooth. The flowers are produced at the end of the branches in very close thick panicles which are large, and of a bright red colour; they appear in July and August, and continue till autumn, but the seeds do not ripen in England.

The fifth sort grows naturally in Canada, Maryland, and several other parts of North America; this hath smooth branches, of a purple colour, covered with a gray pounce. The leaves are composed of seven or eight pair of lobes terminated by an odd one; the lobes are spear-shaped, four inches and a half long, and one broad in the middle, terminating in acute points, and are a little sawed on their edges; they are of a lucid green on their upper surface, but hoary on their under, and are smooth. The flowers are produced at the end of the branches in large panicles, which are composed of several smaller, each standing upon separate foot-stalks; they are of a deep red colour, and the whole panicle is covered with a gray pounce, as if it had been scattered over them. This sort flowers at the same time with the fourth, but does not ripen seeds here.

The sixth sort grows naturally in most parts of North America, where it is known by the title of Beech Sumach, probably from the places where it grows. This is of humbler growth than either of the former, seldom rising more than four or five feet high, dividing into many spreading branches which are smooth, of a light brown colour, and are pretty closely garnished with winged leaves; they are composed of four or five pair of narrow lobes terminated by an odd one; they are entire, about two inches long, and half an inch broad, ending in acute points; they are of a light green on both sides, and in autumn change purplish. The midrib which sustains the lobes, has on each side a winged or leafy border, which runs from one pair of lobes to another, ending in joints at each pair, by which it is easily distinguished from the other sorts. The flowers are produced in loose panicles at the end of the branches; they are of a yellowish herbaceous colour, and appear in July, but the seeds do not ripen in England.

These six sorts are hardy plants, and will thrive in the open air in England. The first and fourth sorts are not quite so hardy as the others, so must have a better situation, otherwise their branches will be injured by severe frost in the winter; they are easily propagated by seeds, when obtained from the countries where they grow, which, if sown in autumn, the plants will come up the following spring; but if they are sown in the spring, they seldom come up till the

R H U

the next spring; they may be either sown in pots, or the full ground. If they are sown in pots in autumn, the pots should be placed under a common frame in winter, where the seeds may be protected from hard frost, and, if in the spring the pots are plunged into a very moderate hot-bed, the plants will soon rise, and have thereby more time to get strength before winter. When the plants come up, they must have a large share of air, and should be gradually hardened to bear the open air, into which they should be removed as soon as the weather is favourable, placing them where they may have the morning sun, and must be kept clean from weeds; and in dry weather, if they are supplied with water, it will greatly promote their growth; but toward autumn it will be proper to stint their growth by keeping them dry, that the extremity of their shoots may harden; for if they are replete with moisture, the early frosts in autumn will pinch them, which will sometimes cause their shoots to decay almost to the bottom, if the plants are fully exposed. If the pots are put under a common frame again in autumn, it will secure the plants from injury, for while they are young, and the upper part of the shoots are soft, so they will be in danger of suffering if the winter proves very severe; but in mild weather they must always enjoy the open air, therefore should never be covered but in frost. The spring following, just before the plants begin to shoot, they should be shaken out of the pots, and carefully separated, so as not to tear the roots, and then transplanted into a nursery in rows three feet asunder, and about one foot distance in the rows. In this nursery they may stand two years to get strength, and then may be transplanted where they are to remain.

The seeds which are sown in the full ground, may be covered the first winter with some old tanners bark to keep out the frost, and in the spring it may be drawn off again after the danger of the hard frost is over; and when the plants come up, they must be kept clean from weeds, which is all the care they will require the first summer; but as the plants in the full ground are apt to grow luxuriant, and continue growing late in autumn, they should be covered to screen them from the early frost, which will otherwise kill their tops, and this often occasions them to die down a considerable length, and frequently almost to the ground in hard winters. In the spring following the plants may be taken up carefully, and transplanted into a nursery at the same distance as before directed. This method of propagating the plants from seeds is seldom practised after a person is once possessed of the plants, for they are very subject to send up a great number of suckers from their roots, whereby they are easily propagated. The suckers of all the sorts may be taken up and planted in a nursery for a year or two to get strength, and then may be planted where they are to remain.

These shrubs are generally planted in plantations of flowering shrubs in large gardens, where they make a fine variety in autumn, especially the second, fourth, and fifth sorts, with their large purple, or red panicles, which have a good effect; but where these are planted, their suckers must be every year taken off, otherwise they will grow up to a thicket and destroy the neighbouring plants.

The seventh sort grows naturally in the east. The seeds of this were sent to the Royal Garden at Paris, where they succeeded, and from thence I received the plant, which grew very well in the open air at Chelsea three years, but the severe winter in 1740 destroyed it, so that it is not quite so hardy as the other sorts. This rises with a shrubby stalk five or six feet high, sending out many irregular branches. The young shoots and foot-stalks of the leaves are covered with a soft brown hairy down; the leaves are composed of three or four pair of oval lobes terminated by an odd one; the inner lobes are small, and the outer large; the first are not more than an inch and a half long, and three quarters of an inch broad, but the

R H U

outer are more than two inches long, and an inch and a quarter broad; the end lobe is heart-shaped, ending in an acute point, and is three inches long and two broad at the base; they are sawed on their edges, and hoary on their under side; the midrib which sustains the lobes, has two leafy membranes running along the sides from joint to joint, which are narrow below, and gradually increase in their breadth to the next joint. When the leaves are broken, they emit a milky juice from the wound. As I have not seen the flowers of this sort, I can give no account of them.

This sort does not put out suckers from the root like the American kinds, so must either be propagated by layers, or by cutting off some of the roots, and planting them upon a gentle hot-bed in the spring, by which method there is great probability it may be propagated, but my plant was too weak for this purpose when it was destroyed.

The eighth sort grows naturally at the Cape of Good Hope; this hath a strong woody stalk which rises ten or twelve feet high, covered with a gray bark, sending out many smooth branches on every side, garnished with trifoliate leaves standing upon pretty long foot-stalks. The lobes of the leaves are oval and entire, about an inch long, and three quarters broad, hoary on their under side, but smooth and of a lucid green on their upper; the flowers are produced from the wings of the leaves in small panicles; they are of an herbaceous colour, and appear in July, but fall away in England without having any seeds succeed them.

The ninth sort also grows naturally at the Cape of Good Hope; this rises with a woody stalk to the height of seven or eight feet, covered with a brown bark, having many irregular branches, garnished with trifoliate leaves standing upon long foot-stalks. The lobes of this sort are angular, and shaped like a rhombus; they are near two inches long, and one broad, downy on their under side, but of a dark green on their upper. The flowers come out in slender bunches from the side of the branches; they are of a whitish herbaceous colour, and soon fall away.

The tenth sort grows naturally at the Cape of Good Hope; this rises with a woody stalk like the eighth, dividing into many branches covered with a brown bark, garnished with trifoliate leaves, whose lobes are wedge or heart-shaped, of a lucid green, and sit close to the foot-stalk. This sort does not flower here so far as I can find, for I have had some of the plants in my care almost forty years, but they have not flowered as yet.

The eleventh sort is a native of the Cape of Good Hope. This hath some resemblance of the former, but the lobes of the leaves are twice as large and oval, with some indentures on their edges; they have several transverse veins running from the midrib to the edges, and are very stiff, of a bright lucid green on both sides. This sort has not flowered here so far as I can learn.

The twelfth sort came from the Cape of Good Hope, where it grows naturally. This rises with a woody stalk seven or eight feet high, dividing into several irregular branches, which are covered with a dark brown bark, and garnished with narrow, spear-shaped, trifoliate leaves, standing upon pretty long foot-stalks. The lobes are two inches long, and half an inch broad in the middle, ending in acute points; they are downy on their under side, but of a lucid green on their upper. The flowers are produced in small loose bunches from the side of the branches; they are small, of an herbaceous colour, and fall off without having any seeds succeed them.

All these African sorts are too tender to live through the winter in the open air in England, so they are planted in pots or tubs, and housed in autumn, and during the winter they must be treated in the same way as other hardy green-house plants. They all retain their leaves through the year, so make a good variety when intermixed with other plants in the green-house in winter. They may be propagated by cut-

R H U

tings, which should be planted in pots filled with loamy earth the beginning of April, and plunged into a very moderate hot-bed, covering them close with hand or bell-glasses, and screening them from the sun in the heat of the day. The cuttings should be now and then refreshed with water, but it should not be given in too great quantity. With this management they will put out roots in about two months, and when they begin to shoot, they should have air admitted to them, and be gradually hardened to bear the open air, into which they must be removed, placing them in a sheltered situation; and when the cuttings have filled the pots with their roots, they should be shaken out of the pots, and parted carefully, planting each into a separate small pot, placing them in the shade till they have taken new root, when they may be intermixed with other exotic plants in a sheltered situation for the summer, and in autumn removed into the green-house.

The thirteenth sort grows naturally on the Island of Ceylon; this rises with a woody stalk ten or twelve feet high, sending out many branches, which are clothed with trifoliate leaves, standing upon pretty long foot-stalks. The lobes of the leaves are oval, about two inches long, and an inch and a half broad, terminating in acute points; they are thick, smooth, and of a lucid green. The flowers are produced in loose panicles at the end of the branches; they are of a whitish herbaceous colour, and small. They seldom appear in England, but when they do they are not succeeded by seeds here.

This plant is tender, so must be placed in a moderate stove, otherwise it will not live through the winter in England. It may be propagated by cuttings in the same way as the former sorts, but requires a warmer bed than those to promote their putting out roots. When they have good roots they should be each transplanted into a separate small pot, and plunged into the tan-bed, and treated in the same way as other tender exotic plants.

The fourteenth sort is a native of the Cape of Good Hope, where it grows to be a large shrub, but in England it seldom rises more than five or six feet high, sending out many branches covered with a bright brown bark, garnished with very narrow trifoliate leaves, standing on very long foot-stalks; the flowers come out in loose panicles at the ends of the branches, and also from the wings of the stalks, of an herbaceous colour, but are small, and fall away, without producing seeds in England.

This may be propagated by cuttings, which should be planted in pots during the summer season, plunging them into a moderate hot-bed, covering them close with hand-glasses; when they have taken root, they should be each planted in a separate pot, shading them till they have taken new root, and in the autumn they must be removed to a green-house.

The fifteenth sort grows naturally in Spain, Italy, and the Levant, where the leaves and branches are used for tanning of leather; this rises with an irregular shrubby stalk to the height of ten or twelve feet, sending out many spreading branches covered with a smooth brown bark, garnished with single, obverse, oval leaves about two inches long, and of the same breadth, rounded at their points, and stand upon long foot-stalks; they are smooth, stiff, and of a lucid green, having a strong midrib, from whence several transverse veins run toward the border. The flowers come out at the end of the branches upon long hair-like foot-stalks, which divide, and branch into large hair-like bunches of a purplish colour; they are small, white, and composed of five small oval petals which spread open; these appear in July, but are not succeeded by seeds in England.

This plant is cultivated for sale in the nursery-gardens near London; it is propagated by layers, which should be laid down in the autumn, and by next autumn they will have taken root, when they may be taken off from the old plants, and transplanted in a nursery, where they may grow a year or two to get

R I B

strength, and then be planted where they are to remain. This shrub is so hardy as to be seldom injured by frost in England.

RIBES. Lin. Gen. Plant. 247. Grossularia. Tourn. Inst. 639. tab. 409. Ribesium. Dill. H. Elth. 246. The Currant-tree.

The CHARACTERS are,

The flower has a bellied empalement of one leaf, cut at the top into five concave obtuse segments; it hath five small, obtuse, erect petals growing to the border of the empalement, and five awl-shaped stamina inserted in the empalement, terminated by incumbent compressed summits opening at their border. The roundish germen is situated under the flower, supporting a bifid style, crowned by obtuse stigmas; it afterward becomes a globular umbilicated fruit with one cell, containing many roundish compressed seeds.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style. Dr. Linnæus and Tournefort both join this to the Gooseberry, making them the same genus, which in a system of botany is very right; but, as they are always separated by gardeners, I have chosen to continue them so here.

The SPECIES are,

1. **RIBES** (*Rubrum*) inerme, racemis glabris pendulis, floribus planiusculis. Lin. Sp. Plant. 200. *Currant without thorns, having smooth hanging bunches, and plain flowers.* Ribes vulgare acidum. J. B. 2. p. 97. *Common sour Currant.*
2. **RIBES** (*Alpinum*) inerme, racemis erectis, bracteis flore longioribus. Lin. Sp. Plant. 200. *Smooth Currant with erect bunches, and bractees longer than the flower.* Ribes Alpinum dulce. J. B. 2. p. 98. *Sweet Alpine Currant.*
3. **RIBES** (*Nigrum*) inerme, racemis pilosis, floribus oblongis. Lin. Sp. Plant. 201. *Currant without spines, having hairy branches and oblong flowers.* Ribes vulgaris fructu nigro. Rudb. Flor. Lapp. 99. *Common black Currant.*
4. **RIBES** (*Americanum*) inerme, racemis glabris, floribus campanulatis. *Currant with unarmed branches, and bell-shaped flowers.* Ribes Americana fructu nigro, Ed. prior. *American Black Currant.*

The first sort grows naturally in the northern parts of Europe, but has been long cultivated in the gardens, and greatly improved, so that at present there are the following varieties in the English garden; the common Currant with small red fruit, the same with white fruit, and another with pale fruit, which is commonly called the Champaign Currant; but, since the two sorts of Dutch Currants have been introduced, and become plenty in the gardens, the old red and white Currants have been almost banished, so that they are rarely to be found in the English gardens at present.

The second sort is kept in a few gardens for the sake of variety, but, as the fruit is very small and has little flavour, it is not cultivated in the gardens.

The third sort grows naturally in Helvetia, Sweden, and other northern countries, and is sometimes cultivated in gardens for its fruit, of which is made a rob, which is greatly esteemed for sore throats, from whence the fruit has been called Squinancy Berries, for their great use in quinsies. As this fruit has a strong disagreeable flavour, it is rarely admitted to the table.

The fourth sort grows naturally in Pennsylvania, from whence the plants were sent to Mr. Peter Collinson several years past, and has been dispersed to most parts of England; this has been by some thought to be the same with the common black Currant, but those who have long cultivated it, know it is very different; the shoots of this being much smaller and more compact, the bark is of a darker colour, the leaves are smaller, thinner, smoother, and have not a rank smell like those of the common sort. The flowers are smaller, bell-shaped, and grow in thinner bunches; the fruit is smaller, and not so round; the plants of this

R I B

this do not produce much fruit, nor is it so good as to merit cultivation, so it is only kept by way of curiosity. The fruit of the red and white Currants are greatly esteemed for the table, and are also very good in fevers; they are cooling and grateful to the stomach, quench thirst, and are somewhat restraining. The jelly made with the juice of this fruit and sugar, is very grateful in fevers, and is used as sauce to the table. This fruit may be procured good much longer than others upon the plants, by planting them in different situations; for if they are planted against pales or walls exposed to the south, the fruit will ripen in June; and by planting some against north walls, if they are screened from birds, and covered in autumn from frost, they may be kept till November; and as the fruit is greatly used for tarts, it is very convenient to have a succession of it for so long a time.

The Champaign Currant differs from the other only in the colour of the fruit, which is of a pale red or flesh colour. The taste is so near to the other, as not to be distinguished; but this being of a different colour, makes a variety on the table.

There are plants of all these sorts with variegated leaves, which are kept in some gardens for the sake of variety; but as these variegations go off when the plants are vigorous, they scarce deserve notice.

These sorts may be easily propagated by planting their cuttings any time from the beginning of September to the middle of October, upon a spot of fresh earth, either in rows at one foot asunder, or in beds, which in the spring must be kept very clean from weeds, and in very dry weather, if they are watered, it will greatly promote their growth. These may remain one or two years in the nursery, during which time they must be pruned for the purposes designed, i. e. either to clear stems about one foot high, if for standards; or if for walls, pales, or espaliers, they may be trained up flat.

Then they should be planted out where they are to remain; for the younger they are planted, the better they will succeed; the best season for which is soon after the leaves begin to decay, that they may take root before winter, so that they may be in no danger of suffering from drought in the spring.

These plants are generally planted in rows at about eight or ten feet asunder, and four distance in the rows, in those gardens where the fruit is cultivated for sale; but the best method is to train them against low espaliers, in which manner they will take up much less room in a garden, and their fruit will be much fairer. The distance they should be placed for an espalier ought not to be less than eight or ten feet, that their branches may be trained horizontally, which is of great importance to their bearing.

Those that are planted against pales or walls should also be allowed the same distance. If they are planted against a south-east wall or pale, it will cause their fruit to ripen at least a fortnight or three weeks sooner than those in the open air; and those which are planted against a north wall or pale will be proportionably later, so that by this method the fruit may be continued a long time in perfection, especially if those against the north pales are matted in the heat of the day.

These plants produce their fruit upon the former year's wood; and also upon small snags which come out of the old wood, so that in pruning them, these snags should be preserved, and the young shoots shortened in proportion to their strength. The only method very necessary to be observed in pruning of them is, not to lay their shoots too close, and never to prune their snags to make them smooth. This, with a small care in observing the manner of their growth, will be sufficient to instruct any person how to manage this plant, so as to produce great quantities of fruit.

These plants will thrive and produce fruit in almost any soil or situation, and are often planted under the shade of trees; but the fruit is always best when they are planted in the open air, and upon a light loamy soil.

R I C

RICINOIDES. See **IATROPHA.**

RICINUS. Tourn. Inst. R. H. 532. tab. 307. Lint. Gen. Plant. 962. [so called, because the seed resembles (ricinus) the animal called by that name, i. e. a tick which infests dogs and oxen. It is also called Palma Christi, because its leaves are said to resemble the palm of the hand.] Palma Christi, vulgò.

The CHARACTERS are,

It hath male and female flowers disposed in the same spike. The male flowers, which are situated on the lower part of the spike, have swelling empalements of one leaf cut into three parts. These segments are oval and concave; the flowers have no petals, but have a great number of slender stamina, which are connected in several bodies, and are terminated by roundish twin summits. The female flowers, which are situated on the upper part of the spike, have empalements of one leaf, which are cut into five segments, and are armed with prickles; they have no petals, but in the center is situated an oval germen, which is closely shut up in the empalement, supporting three short styles, which are bifid, crowned by single stigmas. The germen afterwards turns to a roundish fruit, having three furrows, divided into three cells, opening with three valves, each cell containing one almost oval seed.

This genus of plants is ranged in the ninth section of Linnæus's twenty-first class, which contains those plants which have male and female flowers on the same plant, whose stamina are joined in various bodies.

The SPECIES are,

1. **RICINUS** (*Vulgaris*) foliis peltatis serratis, subtus glaucis, petiolis glanduliferis. *Ricinus with target-shaped sawed leaves which are gray on their under side, and foot-stalks bearing glands.* Ricinus vulgaris. C. B. P. 432. *Common Palma Christi.*
2. **RICINUS** (*Americanus*) foliis peltatis subserratis, lobis amplioribus utrinque virentibus. *Ricinus with target-shaped leaves, which are sawed, whose lobes are large and green on both sides.* Ricinus Americanus major. C. B. P. 432. *Great American Palma Christi.*
3. **RICINUS** (*Urens*) foliis peltatis inæqualiter serratis, capsulis hispidis. Tab. 219. *Ricinus with target-shaped leaves which are unequally sawed, and prickly capsules to the fruit.* Ricinus Americanus major, caule virescente. H. R. Par. *Greater American Palma Christi with a greenish stalk.*
4. **RICINUS** (*Rugosus*) foliis peltatis serratis, capsulis rugosis non echinatis. Tab. 220. *Palma Christi with target-shaped sawed leaves, and rough capsules to the fruit which are not prickly.*
5. **RICINUS** (*Africanus*) foliis peltatis serratis, lobis maximis, caule geniculato, capsulis echinatis. *Ricinus with target-shaped sawed leaves, having the largest lobes, a jointed stalk, and prickly covers to the seeds.* Ricinus Africanus maximus, caule geniculato rutilante. H. R. Par. *Greatest African Palma Christi, with a reddish jointed stalk.*
6. **RICINUS** (*Inermis*) foliis peltatis serratis, lobis maximis, caule geniculato, capsulis inermis. *Palma Christi with sawed target-shaped leaves, having very large lobes, a jointed stalk, and smooth covers to the seeds.*
7. **RICINUS** (*Minor*) foliis palmatis serratis, profundius divisilis capsulis echinatis. *Ricinus with hand-shaped sawed leaves which are deeply divided, and prickly covers to the seeds.* Ricinus Americanus minor. C. B. P. 432. *Small American Palma Christi.*

The first sort grows naturally in Sicily, and other warm parts of Europe. This rises with a strong herbaceous stalk to the height of ten or twelve feet; the joints are at a great distance from each other; the stalk and branches are of a gray colour; the leaves are large, and have long foot-stalks; they are deeply divided into seven lobes which are sawed on their edges, and are gray on their under side; at the division of the lobes is a sort of navel, where the foot-stalk joins the leaves on their under side. The flowers are disposed in long spikes, which rise at the division of the branches; the lower part of the spikes are garnished with male flowers, which have swollen empalements, divided into three parts which open, and shew a great

a great number of slender stamina, terminated by whitish summits, and are connected at their base into several small bunches. The female flowers which occupy the upper part of the spike, have prickly empalements which inclose the roundish germen, upon which sit three short styles, crowned by oblong stigmas. The germen afterward becomes an oval capsule with three deep channels, closely armed with soft spines, and divided into three cells, each containing one oblong striped seed.

The second sort grows naturally in the islands of the West-Indies, where it is called *Agnus Castus*, or Oil-tree. This is often confounded with the former, most of the botanists supposing they are the same plant; but as I have cultivated both more than thirty years, in which time I have never observed either of them to vary, so I think there can be no doubt of their being different plants. This hath brown stalks which divide into two or three branches, which rise six or seven feet high; the leaves are broader, and not so deeply divided as those of the former; they are of a deep green on both sides, and are unequally sawed. The spikes of flowers are shorter, the seed-vessels rounder, and of a brownish colour, and the seeds are much less, and of a brown colour.

The third sort grows naturally in the West-Indies, and is often confounded with the former, but is very different. The stalk of this sort is thick, herbaceous, and of a grayish green; the joints are closer than those of the former sorts; it rises about four feet high, and divides into three or four branches which spread almost horizontally; the leaves are large, of a deep green on their upper side, but grayish on their under; they are deeply cut into six or seven lobes or segments, which are unequally sawed on their edges. The spikes of flowers are loose, the covers of the capsules are green, and closely armed with soft spines, and the seeds are smaller and lighter coloured than those of the second sort.

The fourth sort grows naturally in both Indies, from both which countries I have several times received the seeds. This rises with an herbaceous stalk about four feet high; the lower part is purplish, and the upper of a deep green; the joints of this are pretty far asunder; the leaves are of a deep green on their upper side, but are paler on their under; they are not so deeply divided as some of the other sorts, and are more regularly sawed, the spikes of flowers are large. The male flowers have more stamina, and their summits are yellow; the capsules are oval and rough, but have no spines; the seeds are small, and of a brown colour.

The fifth sort grows naturally in Africa, and also in both the Indies; this rises with a large reddish stalk to the height of ten or twelve feet, which has many joints, and divides into several branches; the leaves are the largest of any species yet known, I have measured some of them which were more than two feet and a half diameter; they are of a dark green, and unequally sawed on their edges, and not so deeply cut as those of some other sorts. The spikes of flowers are large, the empalement of the flowers are brown, the summits on the stamina of the male flowers are whitish; the capsules are large, oval, and closely armed with soft spines; the seeds are very large, and beautifully striped.

The sixth sort grows naturally in the Spanish West-Indies, from whence the late Mr. Robert Millar sent me the seeds. The plants of this sort are in every respect like those of the fifth, but the capsules which inclose the seeds are smooth; and this difference is permanent, therefore it may be put down as a distinct species.

The seventh sort grows naturally in Carolina, and several other parts of America; of this there are two varieties, if not distinct species; one of them has a red stalk, and the other a pale green stalk; they are distinguished by the inhabitants of America, by the title of red and white Oil-seed. The stalks of these seldom rise more than three feet high, they some-

times divide at the top into two or three branches; the leaves are much less than those of the other sorts, and are deeper divided; their borders are unequally sawed, and the segments of the leaves are frequently cut on their sides. The spikes of flowers are smaller and more compact than those of the former sorts; the capsules are smaller, rounder, and of a light green, and are closely armed with soft spines; the seeds are small, and are finely striped.

There are some other species which grow naturally in both Indies, but have not been examined by any curious botanist; for I have received seeds of three or four sorts, which appeared to be very different from any of the known sorts, but the seeds of some were too old to grow, and the other were killed before their seeds were ripe.

The sorts here enumerated, I have cultivated several years, and have always found they have kept their difference, so that I have no doubt of their being distinct species; and unless they are thus tried, there is no possibility of determining their specific difference; for when the plants are found growing in different soils and situations, they have such different appearances, as may deceive the most skilful botanist.

These plants are generally annuals in these countries, though in their native places of growth they continue longer; and in England the plants are often preserved through the winter (especially the first sort) but young plants are much preferable to those which are thus preserved; therefore few persons are at the trouble to keep them, unless when the seasons prove so bad as that their seeds do not ripen, whereby the species might be lost, if the plants are not preserved through the winter.

These plants are propagated by seeds, which must be sown upon a hot-bed in the spring, and when the plants are come up, they should be each planted into a separate pot filled with light fresh earth, and plunged into a fresh hot-bed, observing to water and shade them until they have taken root; after which they must have a great share of free air when the season is mild, otherwise they will draw up tall, and be very weak; and as these plants grow very fast, their roots will in a short time fill the pots; therefore they should be shifted into larger pots, filled with the like fresh earth; and toward the latter end of May, when the season is warm, they may be hardened to endure the open air by degrees; and then if some of the plants are shaken out of the pots, and planted out in a very rich border, and in dry weather duly watered, they will grow to a very large size, particularly the first and fifth sorts, which I have seen upward of ten feet high in one season, and these plants have produced a great quantity of flowers and seeds: but if you intend to preserve any of the plants through the winter, they must not be planted in the full ground, because after their roots have been widely extended, there will be no transplanting them with safety; therefore the best way is to shift them into larger pots from time to time, as their roots shall require, placing them in the open air during the summer season in some warm situation, where they may remain until October, when they must be removed into the house with other exotic plants, observing to water them sparingly in winter, and also to admit the free air in mild weather; for they only require to be protected from frost and cold winds, so that they will endure the winter in a warm green-house, without any addition of artificial warmth.

These plants deserve a place in every curious garden for the singular beauty of their leaves (notwithstanding their flowers make no great appearance) especially those sorts which may be propagated every year from seeds; because those persons who have no green-house to place them into in winter, may cultivate them as other annual plants, amongst which these being placed, either in pots or borders, afford an agreeable variety; but it must be observed, as these are large-growing plants, never to place them too near other plants of less growth, because they will overbear and destroy them;

them ; and those which are planted in pots should be allowed room for their roots to expand, and must be frequently watered, otherwise they will not grow very large.

The inhabitants of the West-Indies draw an oil from the seeds of these plants, which serves for the use of their lamps ; and as the plants come up as weeds in those warm countries, so they are at no trouble to cultivate the plants, but employ their negroes to collect the seeds from the plants which grow naturally, whereby they are furnished with the oil at a small expence. This oil is good to kill lice in children's heads ; and of late years it has been a most effectual remedy for the dry belly-ach, which was a fatal distemper in the West-Indies ; it has also been found serviceable in England, in such disorders where no other medicine will pass through the body. This oil is falsely called Castor Oil in the West-Indies, from the corrupt title of *Agnus Castus* there given to the plant.

The seeds of the first sort is the *Cataputia* major of the shops ; these have been formerly given by some persons to purge watery humours, which they do both upward and downward with great violence, so that at present these seeds are rarely used.

RIPENING of FRUIT.

The METHOD of producing EARLY FRUITS.

In order to have early fruit, a wall should be erected ten feet high, and in length according to the number of trees intended for three years forcing ; the method of constructing these walls is fully explained under the article *WALL*.

This being done, a border may be marked out about four feet wide on the south side of it, and some scantlings of wood, about four inches thick, must be fastened to the ground in a strait line, on the outside of the border, to rest the glass lights upon ; which lights are to slope backward to the wall, to shelter the fruit as there shall be occasion.

Bars about four inches wide, cut out of the whole deal, must be placed between these glasses, so that the lights may rest on them. There must also be a door shaped to the profile of the frame at each end, that it may be opened at either of the ends, according as the wind blows.

The frame before-mentioned should be made so, that when the first part has been forced, the whole frame may be moved the next year forward, and the succeeding year forward again, so that the trees will be forced every third year ; and having two years to recover themselves, will continue in vigour many years. These trees should be well grown before they are forced, otherwise they will soon be destroyed ; and the fruit produced on grown trees will be much fairer and better tasted, than on fresh planted trees.

The fruit that may be planted in these frames are ;

The *Avant*, the *Albemarle*, the *Early Newington*, and *Brown Nutmeg Peaches*.

Mr. Fairchild's Early, the *Elruge* and *Newington Nectarines* ; the *Masculine Apricot* ; the *May Duke* and *May Cherry*.

As for *Grapes*, the *Chasselas* and *Black Cluster*.

Gooseberries ; the *Dutch White*, the *Dutch Early Green*, and the *Walnut Gooseberries*.

Currants ; the large *Dutch White*, the large *Dutch Red Currants*.

It has been found by experience, that the trees will be injured, if the heat be applied before the middle or end of January ; and that the time for applying the heat for bringing either *Duke* or *May Cherries*, is about the middle of that month, and applying heat at the same time would do for *Apricots* ; so that the *Masculine Apricot* will, by the beginning of March, be as large as *Duke Cherries*, and will be ripe by the beginning of May.

Cherries thus forced will not hold so well as *Apricots*, though the former will last, perhaps, for seven years in good plight, but *Apricots* will thrive and prosper thus many years.

Fairchild's Early Nectarine commonly ripens about

the end of May, if they are forced at the same time ; and the *Brugnon Nectarine* will follow that. As to the forward sorts of *Plums*, they ripen about the latter end of May.

Gooseberries will produce green fruit fit for tarts in March, and probably will ripen about the beginning or middle of April at the farthest.

Currants might, by the same heat that brings *Cherries* in April, be forced to produce ripe fruit at the same time, if not sooner.

As for the distance of these trees one from another, it need not be so great as is directed for those planted in the open air, because they will never shoot so vigorously nor last so long, therefore eight or nine feet will be sufficient.

The higher parts of the wall being furnished with *Apricots*, *Cherries*, *Nectarines*, *Peaches*, and *Plums*, the lower small space between them may be filled up with *Currants*, *Gooseberries*, and *Roses*.

The trees against that part of the wall which is designed for forcing, should be pruned as soon as their leaves begin to decay, that the buds on the branches which are left may be benefited, by receiving all the nourishment of the branches, whereby they will become turgid and strong, by the time the walls are heated.

As to the nailing of these trees.

Every branch or shoot must be laid as close to the wall as can be ; for the fruit which is near the wall will be ripe a month sooner than those that lie but four inches from it.

Sometimes it happens, that the tops of such trees have blossoms above a month or six weeks before the bottom ; and sometimes one branch has been full of blossoms, when there have been half a score or more branches of the same tree, which have not stirred till the fruit of the first blossoms has been almost grown, notwithstanding which the tree has done very well ; and it is no uncommon thing for such trees to have fruit ripening upon them for near three months continually.

As for *Gooseberries*, those plants which are planted in these frames, should be such as have been spread and trained, when as many shoots have been nailed to the wall as may conveniently be done, others may be left at a distance from it, to succeed them in ripening.

If they are taken up in autumn, and properly managed, they will bear fruit the first year as well as if they had not been transplanted, but these seldom last longer than two or three years.

The *Currants* may be ordered after the same manner, and also the *Roses* ; and the best kind of *Rose* for this purpose, is the *monthly Rose*, which ought always to be topped about the end of July or the beginning of August, to make them put out a good number of flower-buds.

As to the laying dung to the wall :

This, before it be laid to the back of the wall, should be thrown up in a heap, and lie eight days, then turned over, that it may be of an equal heat every where, and constant.

When it has been thus prepared, it should be laid about four feet thick at the base, and so sloping, till it is but two feet wide at the top.

It should be laid at first within four inches of the top of the wall, for it will sink two feet in six weeks time ; and then some fresh dung must be laid, because the first heat will not do much more than swell the buds of the trees, or bring them to flower.

But, according as the frosts shall have happened to have had more or less influence over the buds, this will happen sooner or later.

If these trees be covered with the glasses a month before the dung is laid against the wall, it will contribute very much to forward their blossoming ; for though their blossoms will not be destroyed by the frosts, yet the more the frosts come at them, they will be the drier and more hard to open.

If the weather is tolerably mild, the trees ought not to be hindered from the benefit of the showers till

the buds begin to stir; but afterwards the glasses should be kept constantly over them, till the influence of the sun is something considerable.

But the doors which are at each end of the frame, should in the mean time be set open, when the wind does not blow too sharp, and the sun shines warm; and if this does not happen in the space of a fortnight, then the doors at both ends may be opened, and mats of bafs or canvas should be hung up over the door-ways to correct the winds, and give the air leave to circulate in the frames.

As for Cherries; about two changes of dung will be sufficient to bring them to a due ripeness in April, supposing each parcel remains six weeks at the back of the wall.

But as for Apricots, Grapes, Nectarines, Peaches, and Plums, if April proves cold, the forcing heat must be continued till May is settled; but some of the glasses should be opened in the morning in March and April, when the wind is still, and the sun warm; and they should be permitted to receive the showers that fall, while the fruit is growing; but while they are in blossom, no rain should come near them, because, if there should be any moisture lodged in the bosom of the flowers, and the sun should shine hot through the glasses, it would be apt to destroy them. The dung that comes from these frames, having lost its heat, may be laid in heaps to rot, for the meliorating of stubborn grounds; or if it is thrown in heaps and mixed with new dung, it will ferment again, and may be used for hot-beds.

Another thing which ought to be observed in planting fruit in these frames is, to plant those fruits which come forward together, and those which come late by themselves, because it will be prejudicial to the forward fruit, to give them any more heat when they have done bearing, when at the same time the later fruits set amongst them may require more heat, and to be continued longer, some of them perhaps requiring an artificial heat till May.

There may also a row or two of Scarlet Strawberries be planted near to the back of this frame, and these you may expect will be ripe by the end of March, or beginning of April.

As for the Vines, they may probably be brought to blossom in April, and have ripe Grapes in June.

There may also be here and there planted a monthly Rose-tree, and Hyacinths, Jonquils, Narcissuses, Polyanthes; also early Tulips might be placed in the borders.

The method of forcing fruit-trees by the help of fire-walls, is fully treated under the article WALLS.

RIVINIA. Plum. Nov. Gen. 48. tab. 39.

The CHARACTERS are,

The empalement of the flower is permanent, and is composed of four oval, concave, coloured leaves. The flower has no petals; it has eight stamina which are longer than the empalement, terminated by small oval summits, and a large roundish germen supporting a short style, crowned by an obtuse stigma. The germen afterward turns to a roundish berry sitting in the empalement, including one hard seed.

The title of this genus was given to it by Father Plumier, who discovered these plants in America, in honour of Augustus Quirinus Rivinus, a famous botanist of Leipfick, who published two volumes of plants in folio, in which the figures of the plants are engraven on copper plates. These were published in 1690.

Dr. Linnæus has applied the title of this genus to the Solanoides of Tournefort, which is totally different from Plumier's plants; and the Doctor has charged Father Plumier with an error in the engraving of the characters of this genus, with eight stamina instead of four, whereas Plumier's plants have eight stamina; but the plant which the Doctor has applied to this title has but four, therefore the mistake is the Doctor's and not Father Plumier's.

The SPECIES are,

1. RIVINIA (*Humilis*) foliis lanceolatis petiolatis inte-

gerrimis, caule fruticoso ramoso. *Rivinia with spear-shaped entire leaves having foot-stalks, and a shrubby branching stalk. Rivinia humilis racemosa, baccis puniceis. Plum. Nov. Gen. 48. Dwarf branching Rivinia with scarlet-coloured berries, sometimes called Currant-tree.*

2. RIVINIA (*Standens*) scandens racemosa, amplis foliis baccis violaceis. Plum. Nov. Gen. 48. *Climbing branching Rivinia, with Nightshade leaves and Violet-coloured berries, commonly called Hoopwith in the West-Indies.*

The first sort rises with shrubby stalks about six or eight feet high, dividing into several spreading branches, covered with a gray spotted bark, garnished with spear-shaped entire leaves, standing upon long slender foot-stalks; these are two inches and a half long, and one broad in the middle, drawing to a point at each end; they are smooth, of a lucid green, and pretty thick consistence, standing alternate, at pretty great distances on the branches. The flowers are produced in long bunches from the side and at the end of the branches, each standing upon a slender foot-stalk near half an inch long; they have no petals, but their empalements are of a scarlet colour; within these are situated eight stamina which are longer than the empalement, terminated by small oval summits; in the center is situated a roundish germen, terminating in a point, supporting a short style. The germen turns to a roundish berry with a thin pulp, surrounding one roundish hard seed; these berries are of a scarlet colour when ripe, and afterward change to a purple; they are by the inhabitants called Currants, but are generally esteemed poisonous.

The second sort rises with a climbing woody stalk to the height of twenty feet, covered with a dark gray bark, and is garnished with oval spear-shaped leaves near three inches long, and an inch and a half broad, standing upon short foot-stalks; they are smooth and entire. The flowers come out in long bunches from the side of the branches, and are shaped like those of the other, and are succeeded by blue berries about the same size as those of the former. This sort grows naturally in Antigua, from whence I have received the seeds; it was also found growing at the Havannah, by the late Dr. Houstoun, who found the first growing in Jamaica.

They are both propagated by seeds, which remain long in the ground before they vegetate; I have had them lie two years before the plants have appeared, but they never rise the same year the seeds are sown.

These berries must be procured from the countries where they naturally grow, and when they arrive, should be sown in pots filled with fresh earth, and plunged into a moderate hot-bed. If this happens late in the autumn or winter, the pots must be plunged into the tan-bed of the stove; but if in the spring, they may be plunged in a common hot-bed under a frame. The earth must be moistened frequently in summer, to promote the vegetation of the seeds, but as they will not come up the same year, so the pots should be removed into the stove before winter, and plunged into the tan-bed; during the winter season, the earth must be sometimes refreshed, but must not be too moist. In the spring the pots may be taken out of the stove, and plunged into a fresh hot-bed to bring up the plants; but if they should not then rise, the earth must not be disturbed, because the plants may come up the following season.

When the plants come up and are fit to remove, they should be each transplanted into a separate small pot, filled with light loamy earth, and plunged into a hot-bed, observing to shade them from the sun till they have taken new root; after which they must be treated in the same way as other plants from the same countries.

These plants are tender, so cannot be preserved in this country, unless they are kept in a warm stove, especially while they are young; but when they have obtained strength, they will live in a moderate warmth in winter, and in summer they may be removed into the

the open air, placing them in a sheltered situation, where they may remain for near three months in the warmest part of summer: during the winter season, these plants should be sparingly watered, for as they grow naturally on a dry soil, much wet will destroy them, especially in cold weather.

They retain their leaves all the year, so make a variety in the stove in winter, and when they flower, make a fine appearance, though their flowers are but small; for as they are produced in long bunches, from almost every joint toward the end of the branches, so the whole plant is well adorned during their continuance; and if they do produce fruit, as that will remain long before it is ripe, so their beauty will be of longer duration.

ROBINIA. Lin. Gen. Plant. 775. Pseudoacacia. Tourn. Inst. R. H. 649. tab. 417. False Acacia.

The CHARACTERS are,

The empalement of the flower is small, of one leaf, and divided into four parts, the three under segments being narrow, but the upper one is broad. The flower is of the Pea bloom kind: the standard is large, roundish, obtuse, and spreads open. The two wings are oval, and have short appendixes which are obtuse. The keel is roundish, compressed, obtuse, and is extended the length of the wings. In the center is situated ten stamina, nine of them being joined together, and the other standing single, terminated by roundish summits. It hath an oblong cylindrical germen, supporting a slender style, crowned by a hairy stigma; these are inclosed by the keel. The germen afterward becomes an oblong compressed pod, inclosing kidney-shaped seeds.

This genus of plants is ranged in the third section of Linnaeus's seventeenth class, which includes those plants whose flowers have ten stamina joined in two bodies.

The SPECIES are,

1. ROBINIA (*Pseudoacacia*) racemis pedicellis unifloris, foliis impari-pinnatis, stipulis spinosis. Hort. Upsal. 212. *Robinia* with branching foot-stalks each supporting one flower, unequal winged leaves, and prickly stipule. *Pseudoacacia vulgaris*. Tourn. Inst. R. H. 649. *Common Bastard Acacia*, or *American Acacia*, called in America *Locust-tree*.
2. ROBINIA (*Echinata*) pedunculis racemosis, foliis impari-pinnatis, leguminibus echinatis. *Robinia* with foot-stalks supporting long bunches of flowers, unequal winged leaves, and prickly pods. *Pseudoacacia Americana*, filiquis echinatis. Boerh. Ind. alt. 11. 39. *American Acacia* with prickly pods.
3. ROBINIA (*Hispida*) foliis impari-pinnatis, foliolis ovatis, ramis pedunculisque hispidis. *Robinia* with unequal winged leaves having oval lobes, and the branches and foot-stalks of the flowers armed with stinging spines. *Pseudoacacia hispida*, floribus roseis. Cateb. Car. 3. p. 20. *Stinging false Acacia*, with a Rose-coloured flower.
4. ROBINIA (*Rosea*) foliis impari-pinnatis, foliolis ovatis acuminatis, ramis nodosis glabris, pedunculis racemosis. *Robinia* with unequal winged leaves, whose lobes are oval, acute-pointed, knobbed smooth branches, and flowers growing in long bunches. *Pseudoacacia flore roseo*. Plum. Cat. *Bastard Acacia* with a Rose-coloured flower.
5. ROBINIA (*Glabra*) foliis impari-pinnatis, foliolis oblongo-ovatis, pedunculis racemosis confertis. *Robinia* with unequal winged leaves having oblong oval lobes, and foot-stalks with long bunches of flowers growing in clusters. *Pseudoacacia arborea* floribus racemosis, filiquis compressis glabris. Hoult. MSS. *Tree-like Bastard Acacia*, with flowers growing in long bunches, and flat smooth pods.
6. ROBINIA (*Alata*) foliis impari-pinnatis, foliolis obversè-ovatis, racemis aggregatis axillaribus, leguminibus membranaceo-tetragonis. *Robinia* with unequal winged leaves, whose lobes are obversely oval, long bunches of flowers growing in clusters from the sides of the branches, and pods having four-winged membranes. *Pseudoacacia filiquis alatis*. Plum. Cat. 19. *False Acacia* with winged pods. Linnaeus titles it *Erythrina foliis pinnatis*, leguminibus membranaceo-tetragonis. Sp. Plant. 707.

Coral-tree with winged leaves and pods, having four membranaceous wings.

7. ROBINIA (*Pyramidata*) foliis duplicato-pinnatis, foliolis ovatis sessilibus, floribus spicatis terminalibus. *Robinia* with doubly-winged leaves, whose lobes are oval and sit close to the midrib, and spikes of flowers terminating the branches. *Pseudoacacia flore pyramidato coccineo*. Plum. Cat. 19. *False Acacia* with a scarlet-coloured flower growing pyramidally.
8. ROBINIA (*Violacea*) foliis pinnatis, foliolis lanceolatis oppositis, racemis axillaribus pedunculis longioribus. *Robinia* with winged leaves having spear-shaped lobes placed opposite, and long bunches of flowers on the sides of the branches, with longer foot-stalks. *Pseudoacacia fraxini folio*, floribus violaceis. Plum. Cat. 19. *False Acacia* with an Ash leaf, and Violet-coloured flowers.
9. ROBINIA (*Latifolia*) foliis impari-pinnatis, foliolis oblongis acuminatis, racemis axillaribus, leguminibus oblongo-ovatis. *Robinia* with unequal winged leaves, having oblong acute-pointed lobes, and bunches of flowers proceeding from the sides of the branches. *Pseudoacacia latifolia*, filiquis latis. Hoult. MSS. *False Acacia* with broad leaves and pods.
10. ROBINIA (*Frutescens*) pedunculis simplicibus, foliis quaternatis subpetiolatis. Hort. Upsal. 212. *Robinia* with single foot-stalks, and leaves growing by fours upon short foot-stalks. *Aspalathus frutescens major latifolius cortice aureo*. Am. Ruth. 283. *Greater, broad-leaved, shrubby Aspalathus*, with a golden bark.
11. ROBINIA (*Caragana*) pedunculis simplicibus, foliis abrupte pinnatis. Hort. Upsal. 212. *Robinia* with simple foot-stalks, and abrupt winged leaves. *Aspalathus arborecens*, pinnis foliorum crebrioribus oblongis. Amman. Ruth. 285. *Tree-like Aspalathus* with oblong lobes.
12. ROBINIA (*Pygmaea*) pedunculis simplicissimis, foliis quaternatis sessilibus. Hort. Upsal. 212. *Robinia* with the most simple foot-stalks, with four leaves sitting close to the stalks. *Aspalathus frutescens minor angustifolius*, cortice aureo. Amman. Ruth. 282. tab. 35. *Smaller shrubby Aspalathus*, with narrow leaves and a yellow bark.

The first sort is the common *Pseudoacacia*, which is a native of North America; the seeds of this were first brought to Paris from Canada by Monsr. Robine, and soon after the seeds were brought from Virginia to England, and many of the trees were raised in several gardens, which for some years, while young, were in great esteem; but as they grew larger, their branches were frequently broken by strong winds in the summer, which rendered them unsightly, so that for several years they were seldom planted in gardens; but of late years it is become fashionable again, and great numbers of the trees have been raised in most parts of England, within a few years past, so that there are few gardens in which there are not some of these trees planted.

This sort grows to a very large size in America, where the wood is much valued for its duration; most of the houses which were built at Boston in New England, upon the first settling of the English, was with this timber, which continues very sound at this time.

It grows very fast while young, so that in a few years from seed, the plants rise to eight or ten feet high; and it is not uncommon to see shoots of this tree six or eight feet long in one summer. The branches are armed with strong crooked thorns, and garnished with winged leaves composed of eight or ten pair of oval lobes, terminated by an odd one; they are of a bright green, entire, and sit close to the midrib. The flowers come out from the side of the branches in pretty long bunches, hanging downward like those of *Laburnum*, each flower standing on a slender foot-stalk. They are of the butterfly or Pea blossom kind, are white, and smell very sweet. They appear in June, and when the trees are well charged with flowers, they make a fine appearance, and their odour perfumes the circumambient air; but they are of short duration, seldom continuing more than one week

in

in beauty; after the flowers fade, the germen becomes an oblong compressed pod, which in warm seasons comes to perfection in England; these ripen pretty late in the autumn.

The leaves of this tree do not come out till late in the spring, and they fall off pretty early in the autumn, which renders it less valuable than it would otherwise be, were these leaves to come out early in the spring.

The second sort is less common than the first. There was a large tree of this kind some years past, growing in the garden of the Bishop of London at Fulham, which produced plenty of seeds. The pods of this sort are much shorter, and closely beset with short prickles, but in other respects agrees with the first sort.

The third sort grows naturally in Carolina, where it sometimes rises to the height of twenty feet, but in England at present it seems to be of low growth; the branches spread out near the ground, and produce their flowers very young, which is a sure sign of its not growing tall here. The branches of this tree, and also the foot-stalks of the flowers, are closely armed with small brown spines, like some sorts of Roses; the leaves are like those of the first sort, but their lobes are larger and rounder. The flowers come out in bunches like those of the former, but are larger and of a deep Rose colour. It flowers about the same time with the first, but has not as yet produced any pods in England.

The fourth sort grows naturally at Campeachy, from whence the late Dr. Houstoun sent the seeds. This rises with a strong woody stem to the height of thirty or forty feet, sending out many strong branches on every side, which have large swelling knots, and are closely garnished with single winged leaves, composed of eight or nine pair of oval lobes ending in points, terminated by an odd one; these are curiously marked with purple spots on their under side, which appear faintly on their upper. The flowers are produced in long close spikes, standing almost erect; they are about half the size of the flowers of the last sort, and are of a fine Rose colour.

The fifth sort was found growing naturally at Campeachy by the late Dr. Houstoun; this rises with a woody branching stalk twelve or fourteen feet high; the old branches are covered with a dark brown bark, but the young shoots and the foot-stalks of the flowers are covered with an iron-coloured down; the leaves are unequally winged; the lobes are oblong, obtuse, and of a pretty thick consistence; they are smooth on their upper side, but have several transverse veins on their under. The flowers are produced at the end of the branches in long close bunches; there are six or seven of them gathered together in clusters. The flowers are but small, and are of a yellowish red colour; the pods of this are like those of the first sort.

The sixth sort grows naturally in Jamaica, where the inhabitants give it the appellation of Dogwood. This hath a strong woody stem which rises forty feet high, and divides into many branches, which are covered with a dark brown spotted bark, and garnished with unequal winged leaves, composed of three or four pair of obverse oval lobes, terminated by an odd one; they are two inches and a half over, smooth on their upper side, but are veined on their under, which are of a buff colour. The flowers come out in branching bunches from the side of the branches; these generally appear at a time when the trees are destitute of leaves, and as they have large clusters of flowers at every joint, so the trees seem covered with them. The bunches at the extremity of the branches are the largest, and are formed pyramidally. The flowers are but small, and do not open so fully as those of the first sort, but are of a pale Rose colour, so make a fine appearance; these are succeeded by pods, having four broad membranaceous wings running longitudinally at the four corners of the pods, and these join at their base, covering the pods entirely; each

of the pods contain four or five oblong kidney-shaped seeds.

The seventh sort was discovered by Plumier, in some of the French settlements of the West-Indies, and it was afterward found by the late Dr. Houstoun growing naturally at Campeachy. This rises with a strong woody stem near thirty feet high, sending out many spreading branches, which are covered with a light gray bark spotted with white, and garnished with double winged leaves, whose lobes are oval and sit close to the midrib; they are of a lucid green on their upper side, but of a pale green on their under. The flowers are produced in long loose pyramidal bunches toward the end of the branches, those on the lower part of the bunch having long foot-stalks, which diminish gradually to the top, so as to form a pyramid; these bunches are almost erect. The flowers are of a scarlet colour, so make a fine appearance. The eighth sort was found growing naturally at Campeachy by the late Dr. Houstoun; this rises with a woody stem to the height of twenty feet, dividing at the top into several spreading branches, which are covered with a very light gray bark, and garnished with equal winged leaves, composed of ten or eleven pair of oval lobes placed opposite; they are of a lucid green on the lower part of the branches, but those toward the end are covered with a soft iron-coloured down. The flowers come out in long bunches from the side of the branches, they are blue, and stand upon long foot-stalks; these are succeeded by pods shaped like those of the first sort, but are downy.

The ninth sort was discovered by the late Dr. Houstoun, growing naturally at Campeachy. This sort rises with a strong woody stem upward of thirty feet high, dividing at the top into many strong branches, covered with a dark grayish bark, spotted with white, and are garnished with winged leaves, composed of six or seven pair of lobes, terminated by an odd one; they are two inches and a half long, and an inch and a half broad, ending in a point, of a lucid green on their upper side, but pale on their under. The flowers are produced in long loose bunches from the side of the branches; they are of a pale Rose colour, and have very long foot-stalks; these are succeeded by oval pods two inches and a half long, and one inch and a half broad, swelling in the middle, where is lodged one or two kidney-shaped seeds.

The tenth sort grows naturally in Siberia and Tartary; this grows with a shrubby stalk eight or ten feet high, sending out several branches which grow erect, covered with a smooth yellowish bark; the leaves have each two pair of oval pointed lobes, which stand upon short foot-stalks. The flowers are produced upon single foot-stalks which come out at the joints of the branches; they are yellow, and shaped like those of the Laburnum, but are smaller; these appear in May, and if the plants stand in a moist soil and shady situation, their pods will succeed the flowers, and the seeds will ripen the end of August.

The eleventh sort grows naturally in Siberia, from whence the seeds were sent to the Imperial Garden at Petersburg, where they succeeded and perfected seeds, which were afterward transmitted to many parts of Europe. This rises with a tree-like stem near twenty feet high, sending out many side branches, garnished with abrupt winged leaves composed of four or five pair of oval lobes placed opposite; the flowers are produced from the wings of the leaves, each foot-stalk having one yellow Pea-blossomed flower, which in a moist season is succeeded by oblong taper pods, containing three or four seeds in each.

The twelfth sort is also a native of Siberia; this is a weak low shrub, seldom rising more than three feet high in England. The branches are slender, and have a light bark, garnished with leaves composed of four oblong lobes which sit close to the branches; the flowers are produced singly upon foot-stalks which arise from the wings of the leaves; they are yellow, and

and appear in April, but are rarely succeeded by seeds in England.

The first sort is generally propagated in the English nurseries, by suckers taken from the roots of the old trees, or by cutting off some of the roots, and planting them upon a gentle hot-bed; these will put out shoots, and become plants; but these are not so valuable as those which are raised from seeds, because they do not make near so great progress in their growth, and are very subject to send forth many suckers from their roots, whereby the ground will be filled with them to a great distance; and these suckers will draw away the nourishment from the old plants, whereby their growth will be greatly retarded.

If this is propagated by seeds, they should be sown on a bed of light earth about the latter end of March or the beginning of April; and if the bed is well exposed to the sun, the plants will appear in about five or six weeks, and will require no farther care but to keep them clear from weeds. In this bed the plants may remain till the following spring, when they should be transplanted into a nursery about the latter end of March, placing them in rows at three feet distance row from row, and a foot and a half asunder in the rows. In this nursery they may remain two years, by which time they will be fit to transplant where they are designed to grow; for as these trees send forth long tough roots, so if they stand long unremoved, the roots will extend themselves to a great distance; therefore they must be cut off when the plants are transplanted, which sometimes occasions their miscarrying.

These trees will grow well upon almost every soil, but best in a light sandy ground, in which they will shoot six or eight feet in one year; and while the trees are young, they make an agreeable appearance, being well furnished with leaves; but when they are old, the branches being frequently broken by winds, render them unightly, especially if they stand in an exposed place; and when the trees grow old, their branches decay, which renders them very disagreeable, and has occasioned their being rooted out of several gardens some years past. This is commonly known by the title of Locust-tree in America, and there are quantities of the seeds annually sent to England with that title.

The second sort is propagated in the same manner as the first, and the trees grow to the same size.

The third sort is at present scarce in the gardens about London, but in Devonshire it is in greater plenty, where the inhabitants give it the title of Raspberry plant, from the young shoots being covered with bristly hairs like the Raspberry plants; this does not produce seeds in England, so it is propagated by cutting off part of the roots, and planting them upon a gentle hot-bed, where they will put out fibres and shoots, and become new plants. This sort should have a warmer situation than the two former, though the ordinary winters in this country never injure it, but in very severe winters their young shoots are sometimes killed in exposed places. It loves a light moist soil.

The fourth, fifth, sixth, seventh, eighth, and ninth sorts, are tender, so cannot be maintained in England, unless they are placed in a stove in winter. These are propagated by seeds, which must be procured from the countries where they naturally grow, for they do not produce any here; these should be sown in small pots filled with earth from the kitchen-garden, and plunged into a hot-bed of tanners bark; if the seeds are good, the plants will appear in six weeks or two months; when these are fit to transplant, they should be carefully shaken out of the pots, and their roots separated; then each plant should be put into a small pot filled with the like earth, and plunged into a hot-bed of tanners bark, observing to shade them till they have taken new root, and then they must have the same treatment as other tender plants from the same countries.

While the plants are young, they are more tender than afterward, therefore it will be proper to keep them in the tan-bed in the stove the two or three first years; but when they have obtained strength, they may be kept in a dry stove of a temperate heat in winter, and in summer they may be exposed to the open air in a sheltered situation; with this management I have kept several of the species, some of which have produced flowers in the Chelsea Garden, and some of the sorts I have propagated by cuttings.

The tenth, eleventh, and twelfth sorts, are propagated from seeds, which should be sown in a shady situation in autumn, and then the plants will come up the following spring; but if the seeds are sown in the spring, the plants seldom rise the same season. When the plants come up, they will require no other care but to keep them clean from weeds till autumn, when, if they have made any progress, they should be transplanted on a north border, at about six inches distance, where they may grow two years, and then should be planted where they are to remain, which should be in a cool moist soil, not too much exposed to the sun.

RONDELETIA. Plum. Nov. Gen. 13. tab. 12. Lin. Gen. Plant. 206.

The CHARACTERS are,

The flower has a permanent empalement of one leaf, sitting upon the germen, cut into five acute points. It has one funnel-shaped petal, with a cylindrical tube longer than the empalement, belled toward the top, and cut into five roundish segments at the brim, which are reflexed. It has five awl-shaped stamina, terminated by single summits; the roundish germen is situated under the flower, supporting a slender style the length of the tube, crowned by an obtuse stigma. The germen afterward becomes a roundish crowned capsule with two cells, inclosing two or three angular seeds in each.

This genus of plants is ranged in the first section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and one style.

The SPECIES are,

1. RONDELETIA (*Americana*) foliis sessilibus, panicula dichotoma. Lin. Sp. Plant. 243. *Rondeletia with leaves sitting close to the branches, and a forked panicle. Rondeletia arborescens, tini facit. Plum. Nov. Gen. 15. Tree-like Rondeletia having the appearance of Tinus.*
2. RONDELETIA (*Asiatica*) foliis petiolatis, oblongis acutis. Flor. Zeyl. 80. *Rondeletia with oblong leaves growing upon foot-stalks. Cupi. Hort. Mal. 2. p. 37.*

The first sort grows naturally in the West-Indies, where Plumier discovered it, and gave it this title in honour of Gulielmus Rondeletius, a famous physician and natural historian of Montpellier.

The seeds of this plant were first sent me by Mr. Robert Millar, who collected them on the north side of the island of Jamaica; he also observed the trees growing plentifully in the Spanish West-Indies; I have also since received the seeds from Barbadoes, which have succeeded at Chelsea. This rises with a woody stalk ten or twelve feet high, branching out on every side; the branches are covered with a smooth greenish bark, and are garnished with oblong leaves ending in acute points; they are entire, and sit very close to the branches; the upper surface is of a lucid green, and the under of a pale green; they are a little crumpled on their surface, and stand alternate. The flowers come out in bunches at the end of the branches, they are white and have little scent. These appear in autumn, and are not succeeded by seeds in England.

The second sort grows naturally at Malabar; this rises with a woody stalk six or seven feet high, dividing into several branches, which are covered with a smooth bark, and garnished with stiff oblong leaves of a lucid green, standing alternate on the lower part of the branches, but by pairs toward the extremity; they have short foot-stalks, and are entire. The flowers are produced in large bunches at the end of the branches; they are of a yellowish white colour, and

have a fragrant odour: these are succeeded by roundish capsules having two cells, each containing three or four angular seeds.

These plants being very tender, cannot be preserved in England, unless they are kept in a warm stove. They are propagated by seeds, which should be sown on a hot-bed early in the spring; and when the plants are come up and fit to remove, they must be transplanted into separate small pots, and plunged into a moderate hot-bed of tanners bark, where they must be treated in the same manner as hath been directed for other tender plants from the same country; in winter they must be placed in the tan-bed in the stove, where these plants will thrive, and in two or three years will flower, when they will make an agreeable variety amongst other tender exotic plants, for they retain their leaves all the year; and those of the second sort being of a lively green, make a fine appearance at all seasons.

R O O T, in Latin Radix.

A Root is that part of a plant, by which it naturally draws in its nourishment. The Roots of plants being of various forms, and each distinguished by a different name, it will not be improper, in this place, to insert the principal of those which are thus distinguished. And first,

A fibrous Root, Radix fibrosa, is that which consists wholly of small fibres, as most sorts of Grass, Pinks, &c.

A tuberous Root, Radix tuberosa, is that which consists of an uniform fleshy substance, and is of a roundish figure, as Turneps, Potatoes, &c.

A bulbous Root, Radix bulbosa, is that which consists either of several coats involving one another, as Onions, Tulips, &c. or of several scales lying over one another, as Lilies, Crown Imperials, &c. The first of these is called a tunicated Root, the last a squamous Root.

A testiculated Root, Radix testiculato, is a double tuberose Root, for it consists of two knobs, resembling a pair of testicles, as in the Orchis.

A handed Root, Radix palmata, is a tuberose Root divided, as it were, into several fingers, as in the handed Satyrians.

A grumous Root, Radix grumosa, is that which is composed of several knobs, as the Anemone, &c.

A granulous Root, Radix granulata, is a kind of grumous Root, with small knobs resembling so many grains of Corn, as in the white Saxifrage.

A tap Root is a tuberose Root extended in length, as in Parsneps, Carrots, &c.

R O S A. Tourn. Inst. R. H. 636. tab. 408. Lin. Gen. Plant. 556. The Rose-tree.

The CHARACTERS are,

The empalement of the flower is of one leaf, divided into five parts at the top, but the base is globular and bell-shaped. The segments are spear-shaped, two of these alternately have appendixes on their sides, two other alternately are naked, and the fifth has often an appendix, and sometimes none. The flower hath five oval heart-shaped petals inserted in the empalement, and a great number of short hair-like stamina inserted in the neck of the empalement, terminated by three-cornered summits. It hath many germen situated in the bottom of the empalement, each having a short hairy style, inserted to the side of the germen, crowned by obtuse stigmas. The fleshy base of the empalement afterward becomes a top-shaped coloured fruit with one cell, including many hairy oblong seeds fastened on each side to the empalement.

This genus of plants is ranged in the fifth section of Linnæus's twelfth class, which contains those plants whose flowers have many stamina inserted in the empalement, and many styles.

The SPECIES are,

1. ROSA (Canina) germinibus ovatis, pedunculisque glabris, caule petiolisque aculeatis. Lin. Sp. Plant. 704. Wild Rose with an oval fruit, having a smooth foot-stalk and prickly branches. Rosa sylvestris vulgaris, flore odorato incarnato. C. B. P. 483. Common wild Rose,

with a flesh-coloured sweet flower, commonly called Wild Briar, Dog Rose, or Hep-tree.

2. ROSA (Spinosissima) germinibus ovatis glabris, pedunculis caule petiolisque aculeatissimis. Lin. Sp. Plant. 705. Wild Rose with oval smooth fruit, but the stalks and foot-stalks extremely armed with spines. Rosa campestris spinosissima, flore albo odorato. C. B. P. 483. Wild prickly Rose with a white sweet flower, commonly called the Burnet-leaved Rose.

3. ROSA (Villosa) germinibus globosis aculeatis, pedunculis hispidis, caule aculeis sparsis, petiolis aculeatis, foliis tomentosis. Lin. Sp. 704. Rose with a globular prickly fruit and foot-stalk, and woolly leaves whose foot-stalks are prickly. Rosa sylvestris pomifera major. C. B. P. 484. The greater, wild, Apple-bearing Rose.

4. ROSA (Eglanteria) germinibus globosis pedunculisque glabris, caule aculeis sparsis rectis, petiolis scabris, foliolis acutis. Lin. Sp. 703. Rose with a globular fruit, a smooth foot-stalk, the stalk armed with erect spines, the leaves pointed, having rough foot-stalks. Rosa sylvestris, foliis odoratis. C. B. P. 483. Wild Rose with sweet-scented leaves, commonly called Sweet Briar.

5. ROSA (Scotica) caule petiolisque aculeatis, foliis pinnatis, foliolis apice incis, fructu globoso. Rose with the stalk and foot-stalk armed with spines, winged leaves whose lobes are cut at their points, and a globular fruit. Rosa pimpinella minor Scotica, flore livide rubente. Edit. prior. Small, Scotch, Burnet-leaved Rose, with a livid red flower.

6. ROSA (Inermis) caule inermi, pedunculis hispidis, calycis foliolis indivisis, fructibus oblongis. Rose with a smooth stalk, a prickly foot-stalk to the flower, the small leaves of the empalement undivided, and oblong fruit. Rosa campestris, spinis carens, biflora. C. B. P. 484. Unarmed Rose having two flowers.

7. ROSA (Hispanica) foliis utrinque villosis, calycis foliolis acutè ferratis, fructu glabro. Rose with leaves which are hairy on both sides, the small leaves of the empalement sharply sawed, and a smooth fruit.

8. ROSA (Scandens) caule aculeato, foliis perennantibus lucidis, flore odorato. Climbing Rose with a prickly stalk, shining evergreen leaves, and a sweet flower. Rosa sylvestris dumetorum scandens sempervirens, myrti folio lucido, flore albo odorato, fructu parvo rotundo & hispido. Mich. Cat. Pl. Ag. Flor. Wild, woody, climbing Rose, with a shining evergreen Myrtle leaf, a white sweet-scented flower, and a small, round, prickly fruit.

9. ROSA (Sempervirens) germinibus ovatis pedunculisque hispidis, caule petiolisque aculeatis. Lin. Sp. Plant. 704. Evergreen Rose with an oval germina, whose foot-stalks are prickly. Rosa moschata sempervirens. C. B. P. 482. Evergreen Musk Rose.

10. ROSA (Virginiana) inermis, foliis pinnatis, foliolis ovatis ferratis utrinque glabris, calycis foliolis indivisis. Rose without thorns, having winged leaves which are smooth on both sides, and the leaves of the empalement undivided. Rosa sylvestris Virginiana pimpinellæ majoris foliis. Raii Hist. Wild Virginia Rose with greater Burnet leaves.

11. ROSA (Lutea) caule aculeato, foliis pinnatis, foliolis ovatis ferratis utrinque glabris, pedunculis brevissimis. Rose with a prickly stalk, winged leaves having oval sawed lobes which are smooth on both sides, and short foot-stalks to the flower. Rosa lutea simplex. C. B. P. 483. The single Yellow Rose.

12. ROSA (Punicea) caule aculeato, foliis pinnatis, foliolis rotundioribus ferratis, petalis emarginatis bicoloribus. Rose with a prickly stalk, winged leaves having rounder sawed lobes, the petals of the flower indented at the top, and of two colours. Rosa punicea. Corn. Can. 111. The Austrian Rose.

13. ROSA (Moschata) caule aculeato scandente, foliis senis glabris, floribus umbellatis. Rose with a prickly climbing stalk, leaves having seven smooth lobes, and flowers growing in umbels. Rosa moschata major. J. B. 2. p. 45. Greater Musk Rose.

14. ROSA (Centifolia) germinibus ovatis pedunculisque hispidis, caule hispido aculeato, petiolis inermibus. Lin. Sp. 704. Rose with an oval germen, stinging foot-stalks,

stalks, and the foot-stalks of the leaves smooth. Rosa entifolia Batavica. Clus. Hist. 1. p. 114. *The Dutch undred-leaved Rose.*

15. Rosa (Damascena) caule aculeato, pedunculis hispidis, calycibus pinnatifidis hirsutis. *Rose with a prickly stalk, bristly foot-stalks to the flowers, and wing-pointed hairy empalements.* Rosa Damascena. Lob. Icon. 206. *Damask Rose.*

16. Rosa (Alba) germinibus ovatis glabris, pedunculis hispidis, caule petiolisque aculeatis. Lin. Sp. 705. *Rose with a smooth oval germen, whose foot-stalks are stinging and the branches prickly.* Rosa alba vulgaris major. C. B. P. 482. *Common great White Rose.*

17. Rosa (Belgica) caule aculeato, foliis subtus hirsutis, calycibus semipinnatis villosis. *Rose with a prickly stalk, leaves which are hairy on their under side, and half-winged hairy empalements to the flowers.* Rosa Belgica five vitrea flore rubicante. Rea. Flor. *The Blush Belgick Rose.*

18. Rosa (Provincialis) caule petiolisque aculeatis, foliis subtus villosis, calycibus semipinnatis hispidis. *Rose with prickly stalks and foot-stalks, leaves hairy on their under side, and bristly half-winged empalements.* Rosa Provincialis major, flore pleno ruberrimo. Boerh. Ind. alt. 2. 252. *Larger Provence Rose, with a very red double flower, commonly called Provence Rose.*

19. Rosa (Incarnata) caule inermi pedunculis aculeatis, calycibus semipinnatis. *Rose with an unarmed stalk, prickly foot-stalks, and half-winged empalements to the flowers.* Rosa incarnata. Park. Par. *The Blush Rose.*

20. Rosa (Gallica) caule subinermi, foliis quinis subtus villosis, calycis foliolis indivisis. *Rose with a stalk almost unarmed, leaves having five lobes, hairy on their under side, and the leaves of the empalement undivided.* Rosa rubra. Ger. *The Red Rose.*

21. Rosa (Cinnamomea) germinibus globosis pedunculisque glabris, caule aculeis stipularibus, petiolis subinermibus. Lin. Sp. 703. *Rose with a smooth globular fruit, prickly branches, and smooth foot-stalks to the leaves.* Rosa odore cinnamomi, flore pleno. C. B. P. 483. *The double Cinnamon Rose.*

22. Rosa (Muscosa) caule petiolisque aculeatis, pedunculis calycibusque pilosissimis. *Rose with armed stalks, the foot-stalks of the leaves and the empalements of the flower very hairy.* Rosa rubra plena, spinosissima, pedunculo muscosa. Boerh. Ind. alt. 2. p. 252. *The most thorny, double, Red Rose, with a mossy foot-stalk, commonly called Moss Provence Rose.*

There are a great variety of double Roses now cultivated in the English gardens; most of them have been accidentally obtained from seeds, so that they must not be esteemed as distinct species, therefore I shall only insert their common names, by which they are known in the gardens, that those who are inclined to collect all the varieties, may be at no loss for their titles. The sorts before enumerated, I believe, are distinct species, as their specific characters are different, though it is difficult to determine which of them are really so; therefore I do not positively assert they are distinct species, though I have great reason to believe they are so.

The varieties of Garden Roses which are not before mentioned:

The Monthly Rose,
The striped Monthly Rose,
The York and Lancaster Rose,
Mrs. Hart's Rose,

} These are all supposed to be varieties of the Damask Rose.

The red Belgick Rose is supposed a variety of the Blush Belgick.

The single Velvet Rose,
The double Velvet Rose,
The Royal Velter,

} These three are all varieties; the last I raised from the seeds of the pale Provence Rose.

The Childing Rose,
The Marbled Rose,
The double Virgin Rose,

} These three have great affinity with each other.

The Cabbage Provence is only a variety of the Common Provence.

The Blush or Pale Provence is a variety of the Red Provence.

The white Monthly
The white Damask

} are varieties of the Damask Rose.

The Frankfort Rose may be a distinct species, but is of little value; the flowers rarely open fair, and have no odour.

The double Sweet Briar
The evergreen Sweet Briar
The double blush Sweet Briar,

} are varieties of the common sort.

The Austrian Rose with red and yellow flowers is only an accidental variety.

The double Yellow Rose is a variety of the single yellow.

The Rosa Mundi is a variety of the Red Rose.

The small, white, and semidouble white, are varieties of the common white.

The first here enumerated is very common in hedges in most parts of England, so is not cultivated in gardens. The Heps of this are used in medicine for making a conserve. The Bedeguar, which is a hairy spongy excrescence occasioned by the bite of small ichneumon flies, grows upon the stalks and branches of this plant, and sometimes upon other sorts of Roses. There are two or three varieties of this Rose commonly met with in hedges, one with a white, another with a red flower, and one with smooth leaves; the two first are evidently varieties, but I doubt if the last is not a distinct species.

The second sort grows naturally in many parts of England; this seldom rises above three feet high. The stalks are slender, and closely armed with small spines; the leaves are small, and are composed of three pair of roundish lobes terminated by an odd one; the flowers are white, and have an agreeable musky scent. This propagates fast by its creeping roots.

The third sort grows naturally in the northern counties in England; this rises with strong stalks to the height of seven or eight feet. The young branches are covered with a smooth brown bark; the spines are but few, and are very strong; the leaves are large, and hairy on both sides; they are composed of three pair of oblong oval lobes terminated by an odd one; these are deeply sawed on their edges; the flowers are large, single, and of a red colour; they appear the beginning of June, and are succeeded by large roundish Heps or fruit, which are set with soft prickles; they have a pleasant acid pulp surrounding the seeds, therefore are by some persons preserved, and made into a sweetmeat, which is served up in deserts to the table.

The fourth sort is the common Sweet Briar, which is so well known as to need no description; this is found growing naturally in some parts of Kent.

The fifth sort is the Dwarf Burnet-leaved Scotch Rose, of which there are two varieties, one with a variegated flower, and the flowers of the other are of a livid red colour; the latter is the same with the Rosa Alpina, pumila, montis rosarum, pimpinellæ foliis minoribus ac rotundioribus flore minimo livide rubente. Hort. Cath. for I have dried specimens of this which were sent me from Italy, and by comparing them with the Scotch Rose, I find they are the same. This sort seldom rises more than a foot high. The stalks are covered with a brown bark, and are closely armed with small spines; the leaves are very small, and have a resemblance to those of Burnet; the flowers are small, and sit close to the branches; the fruit is round, and of a deep purple colour, inclining to black when ripe.

The sixth sort rises to the height of six or seven feet. The stalks and branches have no spines, but are covered with a smooth reddish bark; the leaves are composed of three pair of thin oval lobes, terminated by an odd one; they are very smooth, of a bright green, and very slightly sawed on their edges, standing pretty far asunder upon the midrib; the foot-stalks of the flowers are armed with bristly hairs; the five leaves of the empalement are long, slender in the middle, but terminate in an oval leafy point; the flowers are single, of a bright red colour, and appear the beginning of May; these are succeeded by long spear-

spear-shaped Heps, which are smooth. The plants produce a second crop of flowers about the end of August, but these fall off, and are not succeeded by Heps.

The seeds of the seventh sort were sent me by Robert More, Esq; from Spain, where he found the plants growing naturally; this rises with strong upright stalks about four feet high, armed with strong thorns. The leaves are hairy on both sides; the lobes are roundish, and sawed on their edges; the small leaves of the empalement are acutely sawed; the flowers are single, of a bright red colour, and appear early in May; these are succeeded by large, smooth, roundish Heps, which ripen the end of August.

The eighth sort was discovered by Signior Micheli, growing naturally in the woods near Florence, who sent it to Dr. Boerhaave of Leyden, in whose curious garden I saw it growing in the year 1727: this hath slender stalks which trail upon the ground, unless they are supported, and, if trained up to a pole or the stem of a tree, will rise twelve or fourteen feet high; they are armed with crooked reddish spines, and garnished with small leaves, composed of three pair of oval acute-pointed lobes, terminated by an odd one; they are of a lucid green, and are sawed on their edges; they continue green all the year; the flowers are small, single, white, and have a musky odour; these in their natural place of growth continue in succession great part of the year, but their time of flowering in England is in June.

The ninth sort grows naturally in Spain; the seeds of this were sent me by Robert More, Esq; who found the plants growing there naturally. This rises with erect stalks four or five feet high, which are covered with a green bark, and armed with strong crooked white spines. The leaves are composed of five oval lobes ending in acute points; they are smooth, of a lucid green, and are slightly sawed on their edges; these continue all the year, and make a goodly appearance in winter. The flowers grow in large bunches or umbels at the end of the branches; they are single, white, and have a strong musky odour; they appear in August, and if the autumn proves favourable, will continue in succession till October.

The tenth sort grows naturally in Virginia and other parts of North America; this rises with several smooth stalks to the height of five or six feet. The young branches are covered with a smooth purple bark; the leaves are composed of four or five pair of spear-shaped lobes, terminated by an odd one; they are smooth on both sides, of a lucid green on their upper side, but pale on their under, and are deeply sawed on their edges; the flowers are single, of a livid red colour, and appear in July; the empalement is divided into five long narrow segments which are entire. This is kept in gardens for the sake of variety, but the flowers have little scent.

The eleventh sort is the single Yellow Rose; this hath weak stalks which send out many slender branches, closely armed with short, crooked, brown spines. The leaves are composed of two or three pair of oval thin lobes, terminated by an odd one; they are smooth, of a light green, and are sharply sawed on their edges; the flowers grow upon short foot-stalks; they are single, and of a bright yellow colour, but have no scent.

The twelfth sort is commonly called the Austrian Rose. The stalks, branches, and leaves are like those of the last, but the leaves are rounder; the flowers are larger; the petals have deep indentures at their points; they are of a bright yellow within, and of a purplish copper colour on the outside; they are single, have no scent, and soon fall away. There is frequently a variety of this with yellow flowers upon one branch, and copper colour upon another. This sort of Rose loves an open free air and a northern aspect.

The thirteenth sort is the Musk Rose; this rises with weak stalks to the height of ten or twelve feet, covered with a smooth greenish bark, and armed with

short strong spines. The leaves are smooth, and composed of three pair of oval spear-shaped lobes, terminating in points ending with an odd one; they are of a light green colour, and sawed on their edges; the flowers are produced in large bunches, in form of umbels, at the end of the branches; these appear in August, and continue in succession till the frost stops them; they are white, and have a fine musky odour. There is one with single, and another with double flowers of this sort. The stalks of these plants are too weak to support themselves, so the plants should be placed where they may have support.

The fourteenth sort is the Dutch hundred-leaved Rose; this rises with prickly stalks about three feet high. The leaves have sometimes three, and at others five lobes; the lobes are large, oval, smooth, and of a dark green with purple edges; the foot-stalk of the flower is set with brown bristly hairs; the empalement of the flower is smooth, and half winged; the flowers are very double, and of a deep red colour, but have little scent.

The fifteenth is the Damask Rose; this rises with prickly stalks eight or ten feet high, covered with a greenish bark, and armed with short spines. The leaves are composed of two pair of oval lobes, terminated by an odd one; they are of a dark green on their upper side, but pale on their under; the borders frequently turn brown, and are slightly sawed; the foot-stalks of the flowers are set with prickly hairs; the empalement of the flower is wing-pointed and hairy; the flowers are of a soft pale red, and not very double, but have an agreeable odour; the Heps are long and smooth.

The sixteenth is the common large White Rose, so well known as to need no description. Of this there are two varieties, one with a half double flower, having but two or three rows of petals, and the other has a smaller flower, and the shrub is of lower growth.

The seventeenth sort is called the Blush Belgick Rose; this rises about three feet high, with prickly stalks. The leaves are composed either of five or seven lobes, which are oval, hairy on their under side, and slightly sawed on their edges; the foot-stalks of the flowers and the empalements are hairy, and without spines; the empalements are large and half-winged; the flowers are very double, of a pale flesh colour, and have but little scent. It generally produces great quantities of flowers. The red Belgick Rose differs from this only in the colour of the flower, which is of a deep red.

The eighteenth sort is the common Provence Rose, which is well known in the English gardens, being cultivated in great plenty in the nurseries, and is one of the most beautiful sorts yet known. The flowers of this sort are sometimes very large, and the petals are closely folded over each other like Cabbages, from whence it is called the Cabbage Rose. The flowers of this sort of Rose have the most fragrant odour of all the sorts, therefore is better worth propagating.

The nineteenth sort is the Blush Rose. The stalks of this rise from three to four feet high, and are not armed with spines; the leaves are hairy on their under side; the foot-stalks of the flowers are armed with some small spines; the empalement of the flower is half-winged; the flowers have five or six rows of petals which are large, and spread open; they are of a pale blush colour, and have a musky scent.

The twentieth sort is the common Red Rose, which is used in medicine. The stalks of this sort grow erect, and have scarce any spines; they rise from three to four feet high; the leaves are composed of three or five large oval lobes, which are hairy on their under side; the small leaves of the empalement are undivided; the flowers are large, but not very double, spread open wide, and decay soon; they are of a deep red colour, and have an agreeable scent. The Rosa Mundi is a variety of this with striped flowers.

R O S

The twenty-first sort is the double Cinnamon Rose; this is one of the smallest flowers, and the earliest of all the kinds. The stalks rise about four feet high, are covered with a purplish smooth bark, and have no spines, but at the joints immediately under the leaves, where they are placed by pairs; they are short and crooked. The leaves are composed of three pair of oval lobes terminated by an odd one; they are hairy on their under side, and are sawed on their edges; the leaves of the empalement of the flower are narrow and entire; the flower is small, double, and has a scent like Cinnamon, from whence it had the title of Cinnamon Rose.

The twenty-second sort is called the Moss Provence Rose, from the resemblance which the flowers of this have to those of the common Provence Rose, yet it is undoubtedly a distinct species; for although the stalks and shoots of this are very like those of the common, yet the plants are difficult to propagate, which the common sort is not. This very rarely sends up suckers from the root, and when the branches are layed down, they are long before they put out roots, so that this sort has been frequently propagated by budding it upon stocks of other sorts of Roses, but the plants so raised are not so durable as those which are propagated by layers.

The stalks and branches of this sort are closely armed with brown spines; the foot-stalks of the flowers and the empalements are covered with long hair-like Moss; the flowers are of an elegant crimson colour, and have a most agreeable odour.

Most of the sorts of Roses are of foreign growth, and have been at various times introduced into the English gardens, but they are generally natives of northern countries, or grow upon the cold mountains in the warmer parts of Europe, so they are very hardy in respect to cold, but love an open free air, especially the Yellow Rose, the Austrian Rose, and the Monthly Rose. The two former will not flower in a warm soil and situation, nor near the smoke of London, and the Monthly Rose will flower much better in a free open air, than within the reach of the smoke of London.

The usual time of these shrubs producing their flowers is from the middle, or latter end of May, till the middle of July.

But in order to continue these beauties longer than they are naturally disposed to last, it is proper to plant some of the Monthly Roses near a warm wall, which will occasion their budding at least three weeks or a month before those in the open air; and, if you give them the help of a glass before them, it will bring their flowers much forwarder, especially where dung is placed to the back side of the wall (as is practised in raising early fruits;); by this method I have seen fair Roses of this kind blown in February, and they may be brought much sooner against hot walls or in stoves, where people are curious this way.

You may also cut off the tops of such shoots which have been produced the same spring early in May, from some of these sorts of Roses which are planted in the open air, and upon a strong soil; this will cause them to make new shoots, which will flower late in autumn, as will also the late removing the plants in spring, provided they do not suffer by drought, as I have several times experienced; but particularly in the year 1718, when I had occasion to remove a large parcel of these plants in May, just as they were beginning to flower; in doing of which I cut off all the flower-buds, and, after having opened a trench where they were to be planted, I poured a large quantity of water, so as to render the ground like a pap; then I took up the plants, and placed them therein as soon as possible, that their roots might not dry; and, after planting them, I watered the ground well again, and covered the surface over with mulch to prevent the drying; after this I repeated watering the plants all over two or three times a week, in the evening, until they had taken root. In three weeks or a month after, the plants shot out again, and produced a

R O S

great quantity of flowers in August and September, which were as fair as those produced in June. The Monthly Rose is the best sort for this purpose, there being no other sort which will flower both early and late so well as this.

The next sort of Rose which flowers in the open air, is the Cinnamon, which is immediately followed by the Damask Rose, then the Blush, York, and Lancaster come; after which, the Provence, Dutch, Hundred-leaved, White, and most other sorts of Roses follow; and the latest sorts are the Virginia and Musk Roses, which, if planted in a shady situation, seldom flower until September; and, if the autumn proves mild, will continue often till the middle of October.

The plants of the two sorts of Musk Roses, should be placed against a wall, pale, or other building, that their branches may be supported, otherwise they are so slender and weak as to trail upon the ground. These plants should not be pruned until spring, because their branches are somewhat tender; so that when they are cut in winter, they often die after the knife; these produce their flowers at the extremity of the same year's shoots in large bunches, so that their branches must not be shortened in the summer, lest thereby the flowers should be cut off. The shrubs will grow to be ten or twelve feet high, and must not be checked in their growth, if you intend they should flower well, so that they should be placed where they may be allowed room.

The lowest shrub of all the sorts here mentioned is the Scotch Rose, which rarely grows above a foot high, so that this must be placed among other shrubs of the same growth, which should have a moist soil and a shady situation. The Red Rose, and the Rosa Mundi, commonly grow from three to four feet high, but seldom exceed that; but the Damask, Provence, and Frankfort Roses grow to the height of seven or eight feet; so that in planting them, great care should be taken to place their several kinds, according to their various growth, amongst other shrubs, that they may appear beautiful to the eye.

The Yellow Rose, as also the Austrian Rose, are both natives of America; these were originally brought from Canada by the French; the other varieties, which are now in the gardens, of these sorts, have been accidentally obtained, and are preserved by budding them on the other sorts. The shrubs of these Roses seldom shoot so strong as most of the other sorts, especially in the light land near London, where they seldom produce their flowers. These are esteemed for their colour, being very different from all the other sorts of Roses; but as their flowers have no scent, and are of short duration, they do not merit the price they are generally sold at.

The Frankfort Rose is of little value, except for a stock to bud the more tender sorts of Roses upon, for the flowers seldom open fair, and have no scent; but it being a vigorous shooter, renders it proper for stocks to bud the Yellow and Austrian Roses, which will render them stronger than upon their own stocks; but the Yellow Roses seldom blow fair within eight or ten miles of London, though in the northern parts of Great-Britain they flower extremely well. This sort must have a northern exposure, for if it is planted too warm, it will not flower.

The Damask and Monthly Rose seldom flower well in small confined gardens, nor in the smoke of London, therefore are not proper to plant in such places, tho' they frequently grow very vigorously there. These always begin to shoot the first of any of the sorts in the spring, therefore frequently suffer from frosts in April, which often destroys all their flowers.

All the sorts of Roses may be propagated either from suckers, layers, or by budding them upon stocks of other sorts of Roses; which latter method is only practised for some peculiar sorts, which do not grow very vigorous upon their own stocks, and send forth suckers very sparingly, or where a person is willing to have more sorts than one upon the same plant;

but where this is designed, it must be observed to bud only such sorts upon the same stock as are nearly equal in their manner of growth; for if there be a bud of a vigorous growing sort, and others of weak growth budded in the same stock, the strong one will draw all the nourishment from the weaker, and entirely starve them.

If these plants are propagated by suckers, they should be taken off annually in October, and transplanted out either into a nursery in rows (as hath been directed for several other sorts of flowering-shrubs) or into the places where they are to remain; for if they are permitted to stand upon the roots of the old plants more than one year, they grow woody, and do not form so good roots as if planted out the first year, so there is more danger of their not succeeding.

But the best method to obtain good-rooted plants is to lay down the young branches in autumn, which will take good root by the autumn following (especially if they are watered in very dry weather,) when they may be taken from the old plants, and transplanted where they are to remain. The plants, which are propagated by layers, are not so apt to send out suckers from their roots as those which are from suckers, therefore should be preferred before them; because they may be much easier kept within compass, and these will also flower much stronger. These plants may be transplanted any time from October to April; but when they are designed to flower strong the first year after planting, they should be planted early; though, as I said before, if they are planted late in the spring, it will cause them to flower in autumn, provided they do not suffer by drought.

Most of these sorts delight in a rich moist soil and an open situation, in which they will produce a greater quantity of flowers, and those much fairer, than when they are upon a dry soil or in a shady situation. The pruning which they require, is only to cut out their dead wood, and take off all the suckers, which should be done every autumn; and if there are any very luxuriant branches, which draw the nourishment from the other parts of the plant, they should be taken out, or shortened, to cause them to produce more branches, if there be occasion for them to supply a vacancy; but you must avoid crowding them with branches, which is as injurious to these plants as to fruit-trees; for, if the branches have not equal benefit from the sun and air, they will not produce their flowers so strong, nor in so great plenty, as when they are more open, and better exposed to the sun, so that the air may circulate the more freely between them.

ROSA SINENSIS. See HIBISCUS.

ROSE THE GUELDER. See OPULUS.

ROSMARINUS. Tourn. Inst. R. H. 195. tab. 92. Lin. Gen. Plant. 35. [so called of Ros, Dew, and Marinus, Lat. belonging to the sea, q. d. Sea Dew, as some say, because formerly growing in great plenty near the shore of the Mediterranean Sea; the vapours thence arising, used to fall on it in the manner of Dew.] Rosemary.

The CHARACTERS are,

The flower has a tubulous empalement of one leaf, compressed at the top, the mouth erect, and divided into two lips; the upper lip is entire, and the under bifid. It hath one petal; the tube is longer than the empalement; the brim is ringent; the upper lip is short, erect, and divided into two parts, whose borders are reflexed; the lower lip is reflexed, and cut into three parts, the middle segment being larger and concave. It hath two awl-shaped stamina inclining toward the upper lip, terminated by single summits, and a four-pointed germen, with a style the shape, length, and in the same situation with the stamina, crowned by an acute stigma. The germen afterward become four oval seeds sitting in the bottom of the empalement.

This genus of plants is ranged in the first section of Linnaeus's second class, which includes those plants whose flowers have two stamina and one style; so that this genus, by his system, with six or seven more,

are removed to a great distance from their congeners, which are ranged in his fourteenth class.

The SPECIES are,

1. ROSMARINUS (*Angustifolia*) foliis linearibus marginibus reflexis, subtus incanis. *Rosemary with linear leaves which are reflexed on their edges, and hoary on their under side.* Rosmarinus hortensis, angustiore folio. C. B. P. 217. *Garden Rosemary with a narrower leaf.*

2. ROSMARINUS (*Latifolia*) foliis linearibus obtusis, utrinque virentibus. *Rosemary with obtuse linear leaves which are green on both sides.* Rosmarinus spontaneus latiore folio. C. B. P. 217. *Broad-leaved wild Rosemary.*

These two sorts have been frequently supposed the same, and the difference accidental; but I have long cultivated both, and have raised them from seeds without finding them vary, so I believe they are distinct species. The leaves of the second sort are broader than those of the first, and their points are obtuse; the flowers are also much larger, and of a deeper colour, and the stalks grow larger, and spread out their branches wider, and the whole plant has a stronger scent. These differences the gardeners, who cultivate the plants for the market, observe.

There are two other varieties of these plants, one of the first sort with striped leaves, which the gardeners call the Silver Rosemary, and is at present rare in the English gardens; all the plants of this which were here before the severe winter in 1740, having been then killed; the other is of the second sort, which is striped with yellow; this the gardeners called the Gold striped Rosemary. The plants of this sort are pretty hardy, so will live in the open air through our common winters if they are upon a dry soil.

These plants grow plentifully in the southern parts of France, in Spain and Italy, where, upon dry rocky soils near the sea, they thrive prodigiously, and perfume the air, so as to be smelt at a great distance from the land; but, notwithstanding they are produced in warm countries, yet they are hardy enough to bear the cold of our ordinary winters very well in the open air, provided they are planted upon a poor, dry, gravelly soil, on which they will endure the cold much better than upon a richer soil, where the plants will grow more vigorously in summer, and so be more subject to injury from frost, and they will not have so strong an aromatic scent as those upon a dry barren soil.

Those sorts with striped leaves are somewhat tender, especially that with silver stripes, so should either be planted near a warm wall, or in pots filled with light fresh earth, and sheltered in winter under a frame, otherwise they are subject to die in frosty weather.

These sorts may be propagated by planting slips or cuttings of them in the spring of the year, just before the plants begin to shoot, upon a bed of light fresh earth; and when they are rooted, they may be transplanted into the places where they are designed to grow; but it will be proper to do this about the beginning of September, that they may take new root before the frosty weather comes on; for if they are planted too late in the autumn, they seldom live thro' the winter, especially if the weather proves very cold; so that if you do not transplant them early, it will be the better method to let them remain unremoved until March following, when the frost is over, observing never to transplant them at a season when the dry east winds blow, but rather defer the doing of it until the season is more favourable; for, if they are planted when there are cold drying winds, their leaves are apt to dry up, which often kills them; but, if there happen to be some warm showers soon after they are removed, it will cause them to take root immediately, so that they will require no farther care but to keep them clear from weeds.

Although these plants are tender when planted in a garden, yet when they are by accident rooted in a wall (as I have several times seen them,) they will endure the greatest cold of our winters, though exposed much to the cold winds; which is occasioned by the

Rubia Tinctorum Madder.

RUBIA, foliis semis Hort. Cliff. 35.

L. Miller delin et Sculp.

ROY

the plants being more stunted and strong, and their roots being drier.

The flowers of the narrow-leaved garden sort are used in medicine, as are also the leaves and seeds.

ROYENA. Lin. Gen. Plant. 491.

The title of this genus was given to it by Dr. Linnæus, in honour of Dr. Adrian Van Royen, late professor of botany at Leyden in Holland.

The CHARACTERS are,

The flower has a bellied permanent empalement of one leaf, whose mouth is obtuse and five-pointed. It is of one petal, having a tube the length of the empalement, but the brim is divided into five segments which turn back. It hath ten short stamina growing to the petal, terminated by oblong, erect, twin summits the length of the tube, and an oval hairy germen sitting upon two styles a little longer than the stamina, crowned by single stigmas. The empalement afterward turns to an oval capsule with four furrows, having one cell with four valves, containing four oblong triangular seeds.

This genus of plants is ranged in the second section of Linnæus's tenth class, which includes those plants whose flowers have ten stamina and two styles.

The SPECIES are,

1. ROYENA (*Lucida*) foliis ovatis scabriusculis. Hort. Cliff. 149. *Royena with oval rough leaves.* Staphylo-dendrum Africanum, folio singulari lucido. Herm. Parad. 232. *African Bladder-nut with a single shining leaf.*
2. ROYENA (*Glabra*) foliis lanceolatis glabris. Prod. Leyd. 441. *Royena with smooth spear-shaped leaves.* Vitis Idæa Æthiopica, buxi minoris folio, floribus albis. Hort. Amst. 1. p. 125. *Ethiopian Whortleberry, with a smaller Box leaf and white flowers.*
3. ROYENA (*Hirsuta*) foliis lanceolatis hirsutis. Prod. Leyd. 441. *Royena with hairy spear-shaped leaves.* Staphylo-dendrum Africanum, folio lanuginoso rosamarinifoliori. Boerh. Ind. alt. 2. p. 235. *African Bladder-nut, with a broader, downy, Rosemary leaf.*

The first sort has been long an inhabitant of some curious gardens in England, but it is not very common here, being very difficult to propagate.

This plant grows eight or ten feet high, and puts out its branches on every side, so may be trained up to a regular head: the branches are clothed with oval shining leaves, which are placed alternately, and continue all the year, so make an agreeable variety among other exotic plants in the green-house, during the winter season. The flowers are produced from the wings of the leaves along the branches, but as they have little beauty, few persons regard them. I have not observed any fruit produced by these plants in England.

The second sort grows naturally at the Cape of Good Hope; this rises with a shrubby stalk five or six feet high, sending out many slender branches, covered with a purplish bark, and garnished with small oval leaves less than those of the Box-tree; they are smooth, entire, and of a lucid green, continuing all the year. The flowers come out from the wings of the leaves round the branches, they are shaped like a pitcher, and are white; these are succeeded by roundish purple fruit, which ripen in the winter.

The third sort grows naturally at the Cape of Good Hope; this rises with a strong woody stalk seven or eight feet high, covered with a gray bark, sending out many small branches alternately, which are garnished with spear-shaped leaves about an inch long, and a quarter broad in the middle; they are hoary, and are covered with soft hairs. The flowers come out upon short foot-stalks from the side of the branches; they are of a worn-out purple colour and small. They appear in July, but are not succeeded by seeds in England.

These plants are too tender to live through the winter in the open air in England, therefore they must be removed into the green-house in autumn, and treated in the same way as Orange-trees, with which culture the plants will thrive. The first and third sorts are difficult to propagate here, for the branches which are laid down seldom put out roots, and those

RUB

which do, are two or three years before they will have made roots sufficient to transplant, and their cuttings very rarely succeed; and these being the only methods by which they can be increased in those countries, where they do not produce seeds, are usually practised. The best time to plant the cuttings, is early in the spring; these should be planted in small pots filled with soft loamy earth, and plunged into a very moderate hot-bed. The pots should be closely covered down with hand-glasses to exclude the external air, and the cuttings refreshed with a little water every eighth or tenth day, according as the earth becomes dry, for much moisture will kill them. If the cuttings shoot, they must be gradually inured to bear the open air, and when they are well rooted, they should be each planted in a separate small pot, and afterward treated as the old plants.

If the plants put out any young shoots from the bottom, they should be carefully laid down in the ground while young, because when the shoots are tender they are more apt to put out roots, than after they are become woody and hard; these branches should be slit in the same manner as is practised in laying of Carnations: they must be frequently, but gently watered, during the warm weather in summer, but in cold weather it must be sparingly given them; when these are rooted, they may be taken off, and treated in the same way as the cuttings.

The second sort is very apt to send up suckers from the roots, which may be taken off with the roots, and thereby increased; or those which do not put out roots, may be laid down in the same manner as the former; and the cuttings of this more frequently succeed than those of the other, so that this sort is much easier propagated.

RUBEOLA. See ASPERULA, GALLIUM, and SHE-RARDIA.

RUBIA. Tourn. Inst. R. H. 113. tab. 38. Lin. Gen. Plant. 119. [takes its name from its red colour, because the root of this plant is used in dyeing a red colour.] Madder; in French, *Garance*.

The CHARACTERS are,

The empalement of the flower is small, cut into four segments, and sits upon the germen. The flower has one bell-shaped petal having no tube, but is divided into four parts. It hath four awl-shaped stamina which are shorter than the petals, terminated by single summits; and a twin germen under the flower, supporting a slender style divided into two parts upward, and crowned by two headed stigmas. The germen afterward become two smooth berries joined together, each having one roundish seed with a navel.

This genus of plants is ranged in the first section of Linnæus's fourth class, which contains those plants whose flowers have four stamina and one style.

The SPECIES are,

1. RUBIA (*Tinctorum*) foliis senis lanceolatis supernè glabris. Madder with six spear-shaped leaves in whorls, whose upper surfaces are smooth. Rubia tinctorum sativa. C. B. P. 333. *Cultivated Dyer's Madder.*
2. RUBIA (*Sylvestris*) foliis inferioribus senis, supernè quaternis binisve, utrinque asperis. Madder with the lower leaves growing by sixes round the stalks, and the upper ones by fours or pairs, which are rough on both sides. Rubia sylvestris aspera, quæ sylvestris Dioscoridis. C. B. P. 333: *Rough wild Madder of Dioscorides.*
3. RUBIA (*Peregrina*) foliis quaternis. Prod. Leyd. 254. Madder with four leaves which are placed round the stalks. Rubia quadrifolia asperima lucida peregrina. H. L. 523. *Foreign four-leaved Madder, with shining rough leaves.*

The first sort which is cultivated for the root, which is used in dyeing and staining of linens, grows naturally in the Levant. This hath a perennial root and an annual stalk; the root is composed of many long, thick, succulent fibres, almost as large as a man's little finger; these are joined at the top in a head, like the roots of Asparagus, and root very deep into the ground; I have taken up roots, whose strong fibres have been more than three feet long; from the upper part

part (or head of the root) come out many side roots, which extend just under the surface of the ground to a great distance; whereby it propagates very fast; for these send up a great number of shoots, which, if carefully taken off in the spring, soon after they are above ground, become so many plants. These roots are of a dark colour on their outside, somewhat transparent, and have a yellowish red pith in the middle, which is tough and of a bitterish taste; from the root arise many large, four-cornered, jointed stalks, which in good land will grow five or six feet long, and, if supported, sometimes seven or eight; they are armed with short herbaceous prickles, and at each joint are placed five or six spear-shaped leaves, about three inches long, and near one broad in the middle, drawing to a point at each end; their upper surfaces are smooth, but their midrib on the under side are armed with rough herbaceous spines; the leaves sit close to the branches in whorls. From the joints of the stalk come out the branches, which sustain the flowers; they are placed by pairs opposite, each pair crossing the other; these have a few small leaves toward the bottom, which are by threes, and upward by pairs opposite; the branches are terminated by loose branching spikes of yellow flowers, which are cut into four segments resembling stars. These appear in June, and are sometimes succeeded by seeds which seldom ripen in England.

The second sort grows naturally in Spain, and in the south of France; this hath perennial roots like those of the first sort, but are much larger; the stalks of this are smaller than those of the first sort, and are almost smooth; their lower parts are garnished with narrow leaves, placed by sevens in whorls round the stalks, but upward they diminish to four, three, and two toward the top; these are rough on both sides; at each joint of the stalk comes out two short foot-stalks opposite, having two small rough leaves, and end with branching foot-stalks, sustaining small yellow flowers. This sort flowers the latter end of June, but does not produce seeds here.

The third sort grows naturally in Spain and the Balearic Islands; I received the seeds of this sort from Gibraltar, and also from Minorca, where the plants grew out of the crevices of the rocks. The roots of this sort are much smaller than those of the two former, but are less succulent; they strike deep into the ground, and send up several slender four-cornered stalks which are perennial; they grow a foot and a half long, and divide into many branches, whose joints are very near each other; they are garnished with short stiff rough leaves, placed by fours round the stalk; they are about an inch long, and half an inch broad in the middle, of a lucid green, and continue all the year. This hath not produced flowers in England.

There is a sort which grows naturally in Wales, and also upon St. Vincent's rock, which has four leaves at each joint, but these are narrower and longer than those of the third sort; the stalks of this are perennial, and the leaves evergreen; so that Mr. Ray has mistaken this plant, having supposed it to be the second, which hath annual stalks rising much higher, therefore I should rather think it might be the third sort, if they were equally hardy; but the third sort is so tender, as to be always killed by severe frosts in England, if exposed to the open air.

The first sort is that which is cultivated for the use of the dyers and callico printers, and is so essential to both manufactories, as that neither of those businesses can be carried on without this commodity; and the consumption of it is so great here, as that upon a moderate computation, there is annually so much of it imported from Holland, as the price of it amounts to more than one hundred and eighty thousand pounds sterling; which might be saved to the public, if a sufficient quantity of it were planted in England, where it might be cultivated to greater advantage than in Holland, the lands here being better adapted to grow this plant. But as the growing of this plant

in quantity, has been for several years discontinued, so the method of culture is not well known to many persons here; and as there is at present an inclination in the public to regain this lost branch of trade (for formerly there was not only enough of this commodity raised in England for our own consumption, but also great quantities of it were sent abroad,) so we shall here give a full account of the culture of the plant, and also of the method of preparing the root for use; and shall begin with the method now practised in Zealand, where the best and greatest quantity of Madder is now raised.

In all the Netherlands, there is no where better Madder cultivated, than in Schowen, one of the islands of Zealand, which is performed in the following manner:

The land which is designed for Madder, if it is strong and heavy, is ploughed twice in autumn, that the frost in winter may mellow it and break the clods; then it is ploughed again in the spring, just before the time of planting the Madder; but if the ground is light, then it is ploughed twice in the spring; at the last ploughing it is divided into lands of three feet broad, with furrows between each land four or five inches deep. Madder requires a loamy substantial soil, not too stiff and heavy, nor over light and sandy; for although it may thrive tolerably well in the latter, yet such land cannot have a second crop of Madder planted upon it in less than eight or ten years interval; but in Schowen, where the land is substantial, they need not stay longer than three or four years, in which interval the ground is sown with Corn, or planted with any kinds of pulse. It is granted, that the best land for producing of Madder is in Schowen, where a gemet of land, which is three hundred square rods of twelve feet each, will yield from one thousand pounds to three thousand pounds weight, according to the goodness of the land and the favourableness of the seasons; but in light land, the quantity is from five hundred to a thousand pounds weight.

The time for planting of Madder begins toward the end of April, and continues all May, and sometimes in very backward springs, there is some Madder planted the beginning of June. The young shoots from the sides of the root are taken off from the mother plant, with as much root as possible; these are called kiemen, and are planted with an iron dibble in rows at one foot asunder, and commonly four kiemen in a row.

The quantity of these slips (or kiemen) as is required to plant one gemet of land, are sold at different prices, according to the price which Madder bears, or to the demand for the plants; they are often sold from sixteen to twenty guilders, and sometimes they have been sold for ten to eleven pounds Flemish, but the lowest price is from fifteen guilders to three pounds Flemish.

The expence of planting out a gemet of land with slips (or kiemen) costs for labour only, from sixteen to twenty guilders, according as the land is heavy or light: there are generally employed six men to plant, two to rake the ground, these earn each a guilder a day; and five or six women or boys, called carpers or pluckers of the shoots or kiemen, these earn twelve Dutch pence a day, or two schillings.

The first year the Madder is planted, it is customary to plant Cabbages or Dwarf Kidney-beans, in the furrows between the beds, but there is always great care taken to keep the ground clean from weeds; this is generally contracted for at two pounds Flemish for each gemet of land.

In September or October, when the young Madder is cleared for the last time that season, the green haulm (or stalks) of the plants, is carefully spread down over the beds, without cutting any part off, and in November the Madder is covered over the haulm with three or four inches of earth.

This covering of the Madder, is performed either with the plough or with the spade; if it is done by the

the first, it costs two guilders and a half, or three guilders in strong land each gemet, and over and above this, one guilder and a half to level the tops of the beds, and make them smooth; but it is better performed with the spade, only it is more chargeable, for that costs from eight to ten guilders each gemet, but at the same time the clods are broken, and the surface of the beds is made smooth and even.

The second year in the beginning of April, which is about the time the kiemen or young shoots are beginning to come out, the earth on the top of the beds should be scuffled over and raked, to destroy the young weeds, and make the surface smooth and mellow, that the kiemen may shoot out the easier above ground; this labour costs three shillings each gemet.

The second summer there must be the same care taken to keep the Madder clean as in the first, and then nothing is planted in the furrows, or suffered to grow there; at the last time of cleaning the ground, in September or October, the green haulm is again spread down upon the beds; and in November the Madder is again covered with earth, in the same manner as the first year.

By this method of culture, one can see how necessary it is to plant the Madder in beds, for thereby it is much easier covered with the earth of the furrows; and hereby the earth of the beds is every time heightened, whereby the Madder roots will be greatly lengthened, and the kiemen or young shoots will have longer necks, and by being thus deeply earthed, will put out more fibres and have much better roots, without which they will not grow; and it is of equal use to the mother plants, for by this method the roots will be longer; and in this consists the goodness and beauty of the Madder, for those which have but few main roots, are not so much esteemed as those which are well furnished with side roots called tengels; a Madder plant that has many of these roots, is called a well bearded Madder plant; therefore one must never cut off these side roots, for by so doing there will be a less crop of Madder, and but few kiemen or young shoots can be produced; besides, by the loss of moisture, sometimes the plants will droop and become weak; and there is great profit in having a large quantity of kiemen to draw in the spring, which are in plenty the second and third years.

The Madder roots are seldom dug up the second year, but generally after it has grown three summers, therefore the culture of the third year is the same as in the second, during the spring and summer.

Before the first day of September, it is forbidden to dig up any Madder in this island; but on that day early in the morning, a beginning is made, and the person who carries the first cart load to the stove, has a premium of a golden rider, or three ducats.

The digging up the Madder of a gemet of land, costs from thirty-six to one hundred guilders, according to the goodness of the crop, and the lightness or stiffness of the ground, but in light land it costs from nine to ten pounds Flemish; the persons who are adroit in this business, are generally paid five shillings Flemish per day.

The Madder produces flowers in the middle of summer, and sometimes a few seeds, but they never ripen here; nor would they be of use to cultivate the plants, since it is so easily done by the kiemen.

Some years past they began to plant here the great wild Madder, which was called French Madder, but this was not esteemed so good for use as the tame Madder, from which it differs much, so that was not continued. The more bitter of taste the roots of the Madder are, when taken out of the ground before it is brought to the stove, the less it will lose of its weight in drying, and is the better afterward for use.

When the Madder is dug out of the ground, it is carried to the stove, and there laid in heaps; in that which is called the cold stove, and separated with hurdles made of wicker, and memorandums kept of each parcel, and to what countryman it belongs, that

each may be dried in their turns, and prepared or manufactured, for which turn generally lots are cast beforehand. The Madder thus carried to the stove is relzyn.

This relzyn is carried about six o'clock in the morning, into the tower or steeple, hoisted in baskets by ropes to the rooms, and divided or spread, where it remains till the next day, two or three o'clock in the morning, about twenty or twenty-one hours; then those roots which have lain in the hottest places are removed to cooler, and those in the cooler are removed to the hotter places nearer the oven. This is continued for four or five days, according as there has been more or less carried there; but it is always the goods of one person, that every one may have his own, and of as equal quality as possible, when it is delivered out.

When the Madder is sufficiently dried in the tower, then it is threshed on the threshing-floor, which is made clean from dirt or filth, and then it is brought to the kiln, and there spread on a hair-cloth for about twenty hours, during which time the kiln is made more or less hot, according as the roots are more or less thick, or the weather being more or less cold.

From the kiln the Madder is moved to the pounding-house, and is there pounded on an oaken block made hollow, with six stampers plated at the bottom with iron bands; these stampers are kept in motion by a mill very much resembling a grist mill, which is turned by three horses; the presence of the pounding-master is here always required, to stir the Madder continually with a shovel, to bring it under the stampers. When the Madder is thus properly pounded, it is sifted over a tub till there is enough to fill a cask: this first pounding, which chiefly consists of the thinnest and smallest roots, and the outside husks with some earth, which by drying and threshing could not be separated, is called mor mull.

What remains in the sieve is put on the block again, and pounded a second time, and when the pounding-master guesses a third part is pounded, then the Madder is taken out again and sifted over another tub, and put into a separate cask, and this is called gor gemeens; that which remains in this second operation, not enough pounded in the sieve, is for the third time put on the block, and pounded till it is all reduced to powder, which is called kor krap.

When the Madder is cleansed from the dirt and mull, and is entirely pounded at once, then it is called oor onberoofde, so that this onberoofde actually consists of the gemeens and krap pounded together, and sifted without separating them from each other.

When there is two thirds of krap, and one third gemeens, which was separately prepared or manufactured, then they are called two and one, or marked 2.

The sweepings of the stove, as also of the ground and beams being swept together is not lost, but is put amongst the mull, or sold by itself.

The sweepings of the mill, and every part of the pounding-place, is also gathered together, and put into a cask; this is called den beer.

When the Madder is thus prepared and put into casks, it is in Zealand examined by sworn assayers and tried, if it is not faulty packed up; that is, whether in the preparing it is properly manufactured, or falsely packed up, and to see if every part of the cask is filled with Madder of equal goodness and quality, not burned in the drying, or mixed with dirt; which the assayers by certain trials, and by weighing and washing of the Madder can know, if it is according to the statutes of the country.

There are sundry statutes made and published by the states of Zealand, concerning the preparing of Madder; as one of the 28th of July 1662, one on the 29th of September, and 31st of October 1671, another on the 23d of September 1699, and the last on the 28th of April 1735: by which statutes, among other things, it is strictly forbidden, That no person shall prepare krap, in which there shall be more than

R U B

two pounds of dirt in a hundred weight; nor above eight pounds in the like weight of onberoofde, or in gemeens more than twelve pounds in a hundred weight.

If the Madder upon trial is found good, the arms of the city or village, and the sign of the stove where the Madder was prepared, is painted on the cask with black paint. The trial of the Madder is in no place more exact, or more religiously observed, than in the city of Zirkzee; therefore the merchants in Germany, who know this, always prefer the Madder of that place to all others, and will not buy any which has not the arms of Zirkzee painted upon the casks, if they are to be had.

We before mentioned the tower, the kiln, &c. where the Madder is dried and prepared for use, the draughts of these are exhibited in the annexed plates, with their explanation: but that a better judgment may be formed of their use, we shall here take notice, that the tower is the place where the Madder is first dried. This tower is heated by fifteen or sixteen pipes or flues of brick-work, which run on each side the tower under the floor, and are covered with low burnt tiles, some of which are loose; so that by taking up these, the heat is moderated and conducted to any part of the tower, the person who has the care of drying the Madder pleases.

The tower has four or five lofts made of strong laths; they are four or five feet above each other, upon which the Madder is laid; these are heated by an oven, which is placed in the room where the work people live, and is by them called the glory.

The kiln is in a room whose length is equal to the breadth of the stove, and is entirely arched over at the top; the oven by which the kiln is heated, is called the hog; this is built upon a stone wall, which rises a foot or two above ground; and the small arch by which the heat passes through every part, has several square little holes in the brick-work, that the heat may come out; over these holes, on the top of the kiln, are laid wooden laths the whole length, and upon them a hair-cloth, on which the Madder is laid to dry, before it is carried to the pounding-place. In the Madder-stoves there is no other fuel used but Friezland turf, which gives an equal and moderate heat.

In the Madder-stoves, the people work more by night than day; first, because at the time of the year when the Madder is brought into the stoves, the nights are much colder than the days; and secondly, that the master, who must be always attentive to his work, may not be interrupted by visitors; and thirdly, because they see less dust; but principally, because the Madder which is pounded in the night is of a much better colour than that which is pounded in the day.

In the Madder-stoves are always constant workmen, one who is the drier, who has the care of drying the Madder in the tower and the kiln; for the right performance of this, art and experience is required, the goodness of the Madder greatly depending on the right drying. This person is a sort of foreman, and has the direction of all the workmen; his pay is five stivers, for every hundred weight of Madder which is prepared in the stove; he has one person under him for his assistant, to perform part of the laborious work, and to be always at hand; this man is paid eighteen or nineteen shillings per week Flemish, which is the constant wages.

The third person is the pounder, who is always present when the Madder is pounding, who with a particular shovel which is small, and fitted to the cavity of the pounding-block, stirs the Madder from time to time, to bring it under the stampers; he is paid four stivers for every hundred weight of Madder.

The fourth is a driver, who with a team of three horses, causes the mill to turn and pound the Madder; his pay for himself and the three horses, from eight to nine stivers per hundred weight, according as he can bargain.

Besides these four, there are five other assistants, who

R U B

lay the Madder on and take it off; this is often performed by the wives and boys of the other workmen; these five have fifty stivers for every three thousand pounds of Madder which is prepared, so they have each ten stivers.

There are nineteen or twenty Madder-stoves in the island of Schowen, which, at an average, prepare in one crop, that lasts from September to February, ten thousand weight of Madder each, which in the whole, amounts to two million pounds weight; and if we suppose, that the Madder is sold at an average for four pounds Flemish per hundred weight, which is a moderate price, one may soon reckon what advantage the culture of this dyeing commodity produces to this one island.

The countrymen pay to the owners of the Madder-stoves, two guilders for preparing every hundred weight of mull, and for each hundred weight of hard Madder; that is, of krap, gemeens, or onberoofde, three guilders, according as they will have them prepared.

The building of a Madder-stove quite new from the foundation, costs in the whole about twenty-four hundred pounds Flemish, which is twelve hundred pounds sterling.

PLATE I.

An explanation of the plan of the cold stove.

- Fig. 1. Is the lower band, whose thickness is fourteen by sixteen inches.
2. The upper band, which is twelve by fourteen inches.
3. The cap and band, which is ten by twelve inches.
4. The upper cap, which is six by seven inches.
5. The two main jambs, which are thirteen by fifteen inches of stone.
6. The half bands and posts, of nine by seven inches.
7. The uppermost half band, which is small, six by eight inches.

PLATE II.

A plan of the arched room cut through perpendicularly in the middle where the kiln stands, with a representation of the kiln.

- AA Is the cut of the arch.
- B The oven of the kiln, which is called the hog; this has no chimney; when the fire is first kindled either with turf or other fuel, the smoke is let out through a small window.
- CCC A stone foundation on which the oven and kiln is built.
- CC Is properly the kiln itself, which must be observed in what manner it is built, with little holes to let out the heat.
- DD Stone bands made for the greater firmness, about the kiln.
- EEEE Iron bars placed to strengthen the kiln, and also to lay the upper long lath upon.
- F Small cross laths over the kiln, which lie from one end C to the other end C upon the kiln, but there are few of these represented, that the small holes of the kiln may better appear.
- G The door of the entrance.

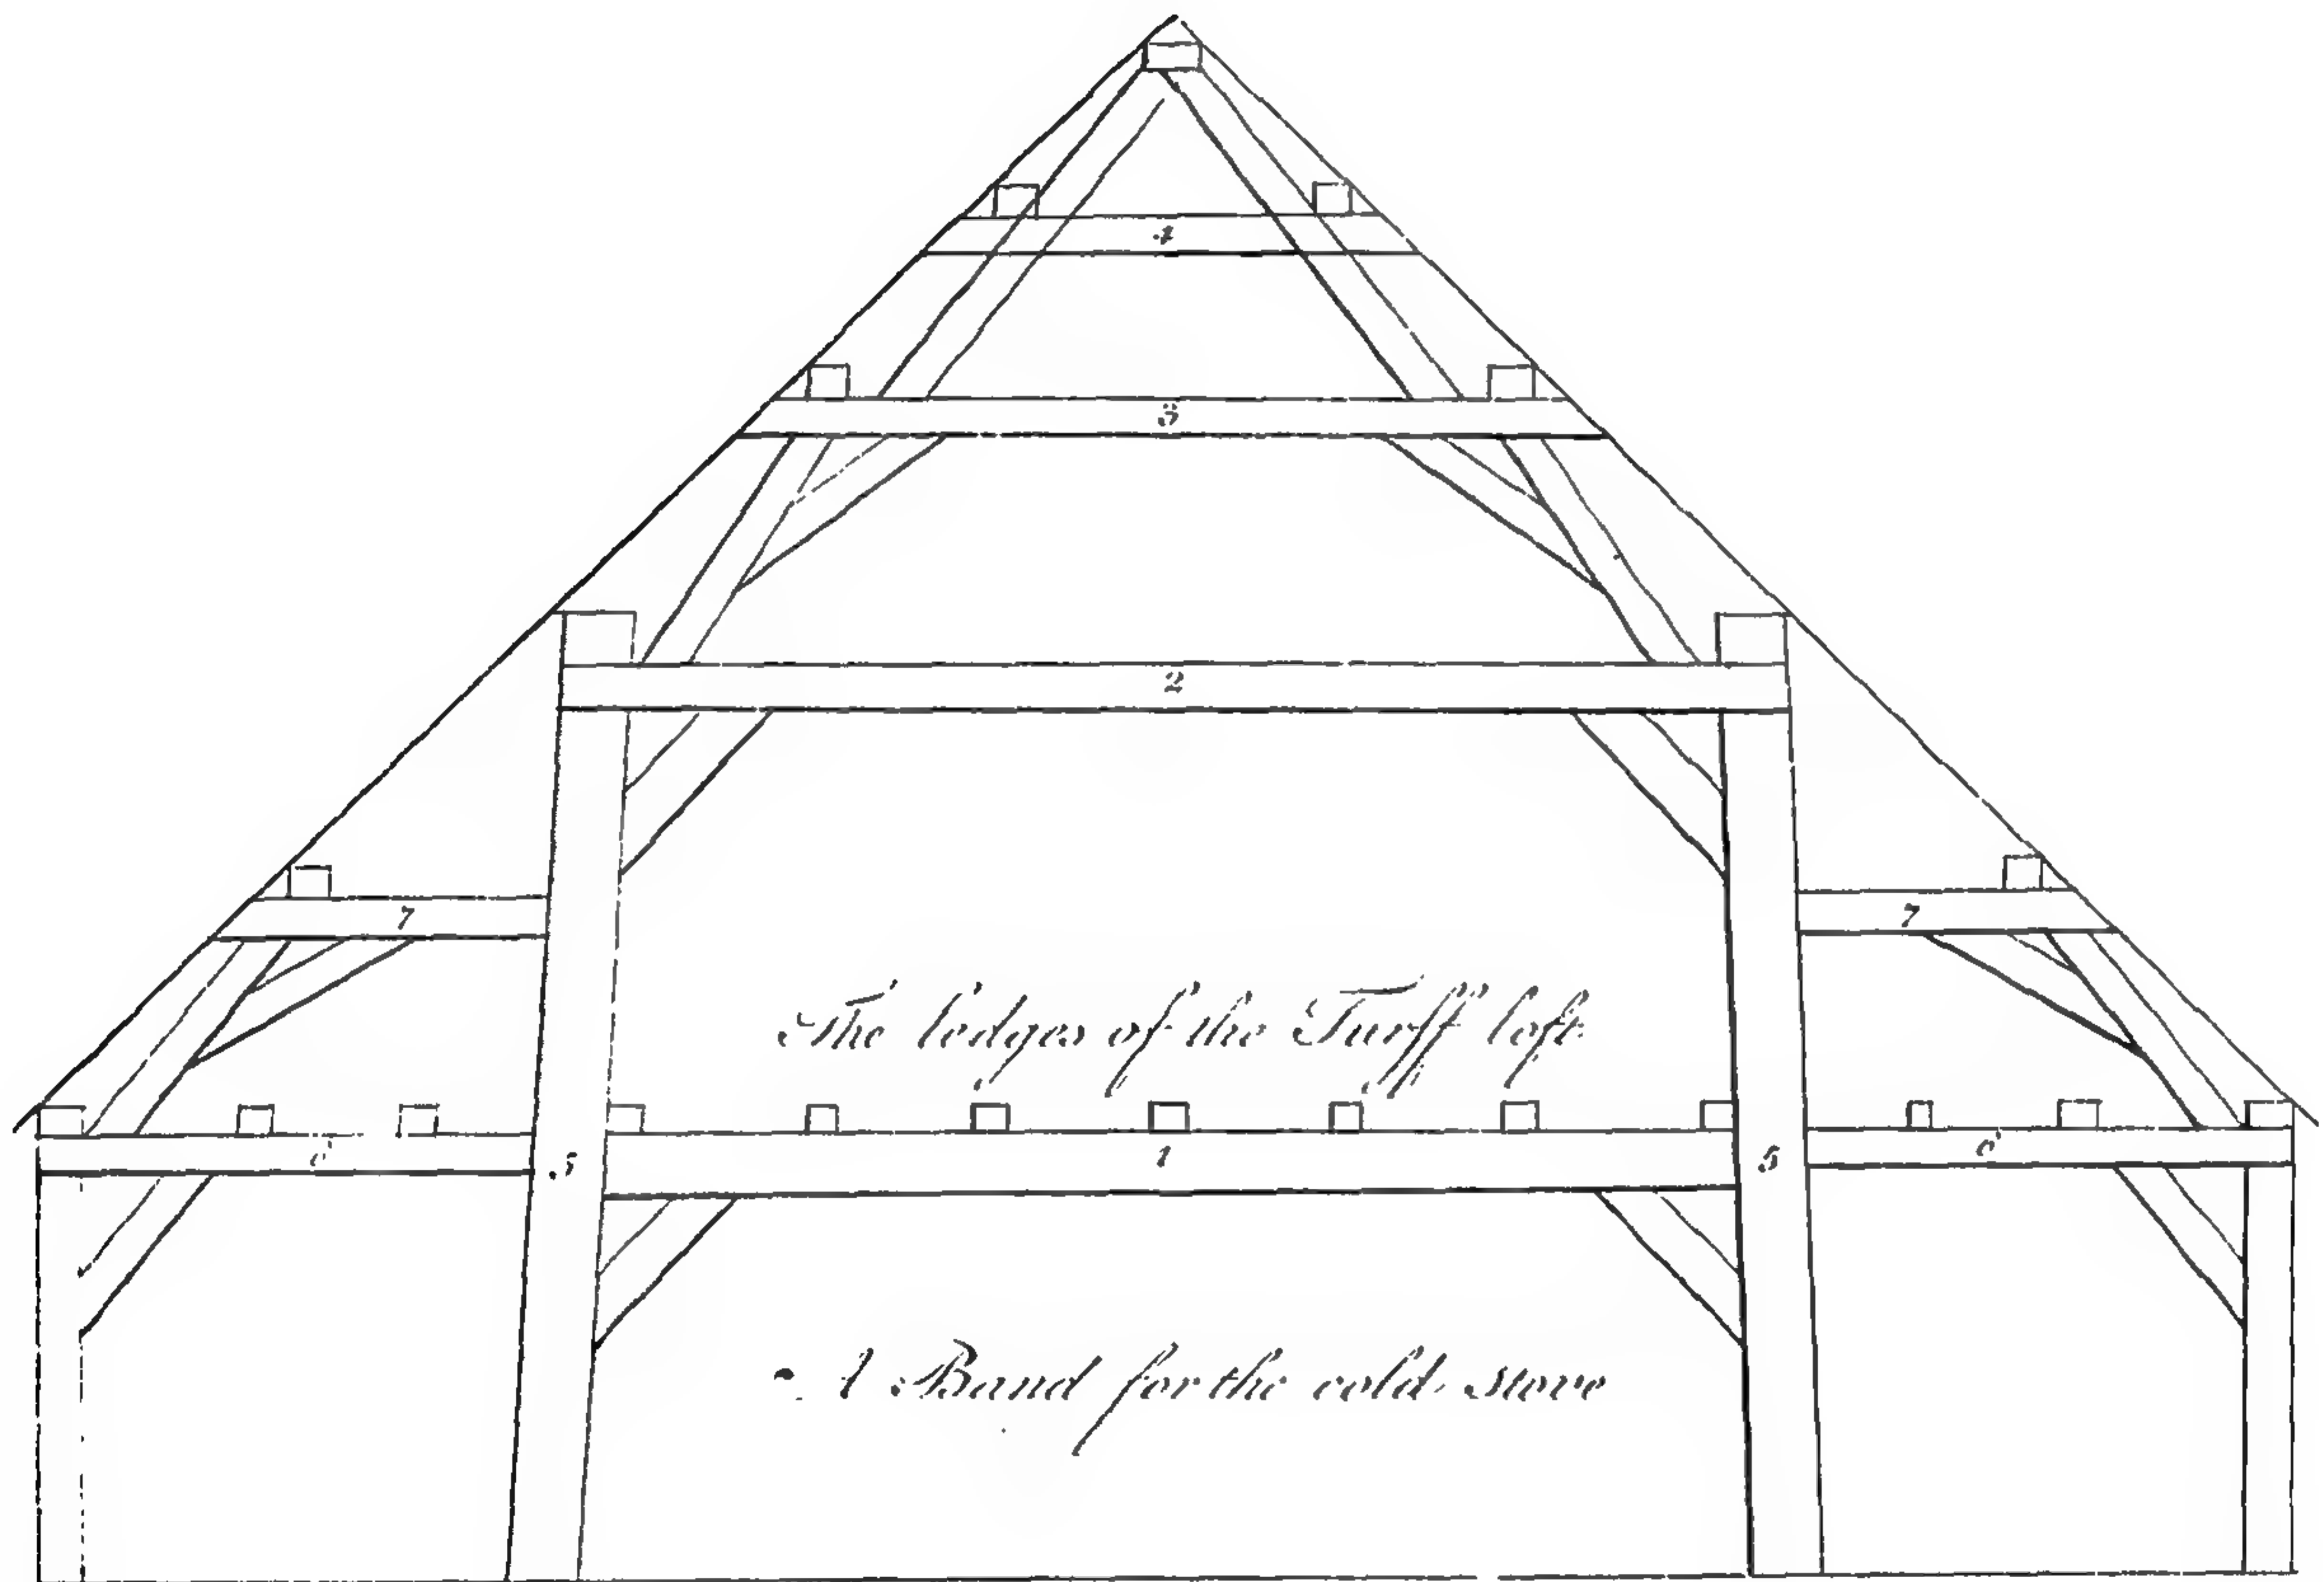

PLATE III.

A plan of the tower where the Madder is first laid to dry.

- A Is the oven of the tower.
- BB The pipes whereby the heat spreads itself, is here shewn by the openings where the tyles are taken off.
- C A sort of stairs by which they climb.
- DD The windlass with its rope and hook, to hoist the Madder to the lofts.

8. The third girder, six by eight inches.
9. The uppermost girder, six by seven inches.
10. The top or cap, four by five inches.

The above account is the method of cultivating Madder in Zealand, where the best Madder is now produced; to this I shall add, what I have observed of the growing of Madder in other parts of Holland, as also the experience I have had of the growth of Madder in England, with an account of the method of planting it here.

In the year 1727, I observed a great quantity of this plant cultivated in Holland, between Helvoetsluys and the Brill; and it being the first time I had ever seen any considerable parcel of it, I was tempted to

R U B

make some enquiries about its culture; and take some minutes of it down upon the spot, which I shall here insert, for the use of such as may have curiosity to attempt the culture of it.

In autumn they plough the land, where they intend to plant Madder in the spring, and lay it in high ridges, that the frost may mellow it; in March they plough it again, and at this season they work it very deep, laying it up in ridges eighteen inches asunder, and about a foot high; then about the beginning of April, when the Madder will begin to shoot out of the ground, they open the earth about their old roots, and take off all the side-shoots which extend themselves horizontally, just under the surface of the ground, preserving as much root to them as possible; these they transplant immediately upon the tops of the new ridges, at about a foot apart, observing always to do this when there are some showers, because then the plants will take root in a few days, and will require no water.

When the plants are growing, they carefully keep the ground hoed, to prevent the weeds from coming up between them; for if they are smothered by weeds, especially when young, it will either destroy or weaken them so much, that they seldom do well after. In these ridges they let the plants remain two seasons, during which time they keep the ground very clean; and at Michaelmas, when the tops of the plants are decayed, they take up the roots and dry them for sale. This is what I could learn of their method of cultivating this plant, to which I will subjoin a few observations of my own, which I have since made upon the culture of Madder in England.

The land upon which I have found Madder thrive best, is a soft sandy loam, and if it has been in tillage some years, it will be better than that which is fresh broken up. This should have at least a depth of two feet and a half, or three feet of good earth, and must be quite clear from Couch, or the roots of any bad weeds; for as the roots of Madder should remain three years in the ground, so where there are any of those weeds which spread and multiply at their roots, they will intermix with the Madder roots, and in three years will have taken such possession of the ground, as to greatly weaken the Madder, and render it very troublesome to separate when the Madder is taken up.

The ground should be ploughed deep before winter, and laid in ridges to mellow; and if it is not too strong, there will be no necessity for ploughing it again, till just before the time of planting the Madder, when the land should be ploughed as deep as the beam of the plough will admit; and there should be men following the plough in the furrows, which should dig a full spit below the furrow, and turn it up on the top; by preparing the ground of this depth, the roots of the Madder will strike down, and be of greater length, in which the goodness of the crop chiefly consists. The land being thus prepared and made level, will be fit to receive the plants. The best time for planting of the Madder is about the middle or the latter end of April, according as the season is more or less forward, which must be determined by the young shoots; for when these are about two inches above ground, they are in the best state for planting.

In the taking up of these shoots for planting, the ground should be opened with a spade, that they may be separated from the mother plants with as much root as possible; for if the roots are broken off, they will not succeed: these plants should be drawn up no faster than they are planted; for if they lie long above ground, they will shrink and their tops will wither, and then they often miscarry; therefore if they are brought from a distant place, there should be great care taken in the packing of them up for carriage; especial regard should be had not to pack them so close, or in so great quantity, as to cause them to heat, for that will soon spoil them; but if they are a little withered

withered by lying out of the ground; their roots should be set upright in water for a few hours, which will stiffen and recover them again.

In the planting of Madder, there are some who make the rows but one foot asunder, others one foot and a half, some two feet, and others who allow them three feet distance; I have made trial of the three last distances, and have found when the roots have been left three years in the ground, that three feet distance row from row is the best; but if it is taken up in two years, two feet asunder may do very well; and the distance in the rows, plant from plant, should be one foot, or a foot and a half.

If there is no danger of the ground being too wet in winter, the plants may be planted on the level ground; but if on the contrary, the ground should be raised in ridges where each row of plants is to be set, that their roots may not reach the water in winter, for if they do, it will stop their downright growth; and this is the reason why the Dutch, who plant Madder in the Low Countries, raise their ridges so high as two or three feet; and in Zealand, where the ground is drier, they raise the beds four or five inches above the intervals, that the wet may drain off from the beds where the Madder is planted.

The method of planting is as follows: viz. the ground being made smooth, a line is drawn across it to mark out the rows, that they may be strait, for the more convenient cleaning, and for the better digging or ploughing of the ground between the rows; then with an iron-shod dibble, holes are made, at the distance which the plants are to stand from each other. The depth of the holes must be in proportion to the length of the roots of the plants, which must be planted the same depth they had been while they were upon the mother plants; for if any part of the root is left above ground, the sun and winds will dry them, which will retard the growth of the plants; and should any part of the green be buried in the ground, it will not be so well; though of the two, the latter will be less prejudicial, especially if there is not too much of the green buried. When the plants are put into the holes, the earth should be pressed close to them to secure them from being drawn out of the ground, for crows and rooks frequently draw the new plants out of the ground before they get new roots, where there is not this care taken: so that in two or three days, I have known half the plants on a large piece of land destroyed by these birds.

If there happens to be some showers of rain fall in a day or two after the plants are planted, it will be of great service to them, for they will presently put out new roots, and become strong; so that if dry weather should afterward happen, they will not be in so much danger of suffering thereby, as those which are later planted. There are some who, from a covetous temper of making most use of the ground, plant a row of Dwarf Peas or Kidney Beans between each row of Madder, and pretend that thereby the land is kept cleaner from weeds; but I am very certain the crop of Madder is injured thereby much more than the value of those things which grow between the rows, as I have experienced; therefore I advise those persons who plant Madder, never to sow or plant any thing between the rows, but to keep the Madder quite clean from weeds, or any other kind of vegetable.

In order to keep the ground thus clean, it should be scuffled over with a Dutch hoe, as soon as the young weeds appear. When a man can perform a great deal of this work in a day, and if it is done in dry weather, the weeds will die as fast as they are cut down; whereas, when the weeds are left to grow in the spring, so as to get strength, they are not so soon destroyed, and the expence of hoeing the ground then will be more than double; besides, there will be danger of cutting down some of the weaker plants with the weeds, if the persons employed to perform this work are not very careful; therefore it is much cheaper, as also better for the Madder, to begin this

work early in the spring, and to repeat it as often as the weeds render it necessary; for by keeping the ground thus constantly clean, the Madder will thrive the better.

During the first summer, the only culture which the Madder requires, is that of keeping it clean in the manner before directed; and when the shoots or haulm of the plants decay in autumn, it should be raked off the ground; then the intervals between the rows should be either dug with a spade or ploughed with a hoeing plough, laying up the earth over the heads of the plants in a roundish ridge, which will be of great service to the roots. The Dutch cover the haulm of their Madder with earth, leaving it to rot upon the ground; this perhaps may be necessary in their country, to keep the frost out of the ground; but as I have never found that the severest winters in England have injured the Madder roots, there is not the same necessity for that practice here.

The following spring, before the Madder begins to shoot, the ground should be hoed and raked over smooth, that the young shoots may have no obstruction; and if there should be any young weeds appearing on the ground, it should be first scuffled over to destroy the weeds, and then raked over smooth; after this, the same care must be taken in the following summer to keep the ground clean; and if it is performed by the hoe plough, the earth of the intervals should be thrown up against the side of the ridges, which will earth up the roots, and greatly increase their strength; but before the ground of one interval is so hoed, the haulm of the plants should be turned over to the next adjoining interval; and if they are permitted so to lie for a fortnight or three weeks, and then turned back again on those intervals which were hoed, observing first to scuffle the ground to destroy any young weeds which may have appeared since the stirring of the ground; then the alternate intervals should be ploughed in like manner, turning the earth up against the opposite sides of the roots; by this method the intervals will be alternately ploughed, and the plants earthed up, whereby the ground will be kept clean, and stirred, which will greatly promote the growth of the roots; and by this method the superficial shoots will be subdued, and the principal roots greatly strengthened. The following autumn the ground should be cleared of the haulm and weeds, and the earth raised in ridges over the roots, as in the foregoing year.

The third spring the roots will furnish a great supply of young plants; but before these appear, the ground should be cleaned and raked smooth, that the shoots may have no obstruction to their coming up; and when the young plants are fit to take off, it should be performed with care, always taking off those which are produced at the greatest distance from the crown of the other plants, because those are what rob them most of their nourishment, and the wounds made by separating them from the old roots are not near so hurtful as those near the crown; for the stripping off too many of the shoots there, will retard the growth of the plants.

The culture of the Madder in the third summer must be the same as the second; but as the roots will then be much stronger, the earth should be laid up a little higher to them at the times when the ground is cleaned; and if all the distant superficial shoots, which come up in the intervals are hoed or ploughed off, it will be of service to strengthen the larger downright root; and as the haulm will now be very strong and thick, the frequent turning it over from one interval to another will prevent its rotting; for if it lies long in the same position, the shoots which are near the ground, where there will be always more or less damp, and being covered with the upper shoots, the air will be excluded from them, which will cause them to rot, for the shoots of Madder are naturally disposed to climb up any neighbouring support; and in places where they have been supported, I have seen them more than ten feet high; but the expence of staking

the plants to support their shoots would be much too great to be practised in general; therefore the other method of turning the haulm over from one interval to the other will be found of great use, for hereby it is kept from decaying, and by so doing the sun is alternately admitted to each side of the roots, which is of more consequence to the growth of the Madder than most people conceive; and from many repeated trials I have found, that where the haulm has decayed or rotted in summer, it has greatly retarded the growth of the roots. There have been some ignorant pretenders who have advised the cutting off the haulm in summer, in order to strengthen the roots; but whoever practises this, will find to their cost the absurdity of this method; for I have fully tried this many years ago, and have always found that every other root, upon which this was practised, was at least a third part smaller than the intermediate roots, whose haulm was left entire. The first occasion of my making this experiment was, because the plants had been set too near each other, and the season proving moist had increased the number and strength of the shoots, so that they were so thick, as that many of them began to rot; to prevent which, I cut off the shoots of every other plant to give room for spreading the others thinner, but soon after this was done, the plants produced a greater number of shoots than before, but they were weaker, and the effect it had upon the roots was as before related; since which time I have frequently repeated the experiment on a few roots, and have always found the effect the same.

As soon as the haulm of the Madder begins to decay in autumn, the roots may be taken up for use, because then the roots have done growing for that season, and will then be plumper and less liable to shrink than if they are dug up at another season; for I have always found, that roots of every kind of plant, which are taken out of the ground during the time of their growing, are very apt to shrink, and lose more than half their weight in a short time; whereas, when they are taken up soon after their leaves decay, they will not soon after shrink much.

When the season for digging up the Madder root is come, it should be done in the following manner, viz. a deep trench should be dug out at one side of the ground next to the first row of Madder to make a sufficient opening to receive the earth, which must be laid therein in digging up the row of roots, so that it should be at least two feet broad, and two spits and two shovellings deep, and should be made as close as possible to the roots, being careful not to break or cut the roots in doing it; then the row of roots must be carefully dug up, turning the earth into the trench before-mentioned. In the doing of this there should be to every person who digs, two or three persons to take out the roots, that none may be lost; and as much of the earth should be shaken out of the roots as possible; and after the principal roots are taken up, there will be many of the long fibres remaining below; therefore, in order to get the roots as clean as possible, the whole spot of ground should be dug of the same depth as the first trench, and the pickers must follow the diggers to get them all out to the bottom. As the digging of the land to this depth is necessary, in order to take up the roots with as little loss as possible, it is a fine preparation for any succeeding crop; and I have always found that the ground where Madder has grown, produced better crops of all kinds than land of equal goodness, which had not the like culture.

After the roots are taken up, the sooner they are carried to the place of drying, the finer will be their colour; for if they lie in heaps, they are apt to heat, which will discolour them; or if rain should happen to wet them much, it will have the same effect, therefore no more roots should be taken up than can be carried under shelter the same day.

The first place, in which the roots should be laid to dry, must be open on the sides to admit the air, but covered on the top to keep out the wet. If a build-

ing is to be erected new, such as the tanners have for drying their skins will be as proper as any, for these have weather-boards from top to bottom at equal distances to keep out the driving rain, but the spaces between being open admit the air freely; and if, instead of plank floors or stages above each other, they are laid with hurdles or basket-work, upon which the roots are laid to dry, the air will have freer passage to the under side of the roots, which will dry them more equally.

In this place they may remain four or five days, by which time the earth which adhered to the roots will be so dry as to easily rub off, which should be done before the roots are removed to the cold stove, for the slower the roots are dried, the less they will shrink, and the better will be the colour of the Madder; and the cleaner the roots are from earth, the better the commodity will be for use when prepared.

After the roots have laid a sufficient time in this place, they should be removed into another building called the old stove, in which there should be conveniences of flues passing through different parts of the floor and the side-walls; in this the roots should be laid thin upon the floors, and turned from time to time as they dry, taking those roots away, which are nearest to the flues which convey the greatest heat, placing them in a cooler part of the room, and removing such of them as had been in that situation to the warmer, from whence the other are taken. The constant care in this particular will be of great service to the quality of the Madder; for when this is properly conducted, the roots will be more equally dried, and the commodity, when manufactured, will be much fairer and better for use.

When the outside of the roots have been sufficiently dried in this cold stove, they should be removed to the threshing floor, which may be the same as in a common barn where Corn is threshed. The floor of this should be swept, and made as clean as possible; then the roots should be threshed to beat off their skins or outside coverings; this is the part which is prepared separately from the inner part of the root, and is called mull, which is sold at a very low price, being the worst sort of Madder, so cannot be used where the permanency or beauty of the colours are regarded; these husks are separated from the roots, and pounded by themselves, which are afterward packed up in separate casks, and sold by the title of mull. If this is well prepared, and not mixed with dirt, it may be sold for about fifteen shillings per hundred weight, at the price which Madder now bears; and this, as is supposed, will defray the whole expence of drying the crop.

After the mull is separated from the roots, they must be removed to the warmer stove, where they must be dried with care: for if the heat is too great, the roots will dry too fast, whereby they will lose much in weight, and the colour of the Madder will not be near so bright; to avoid which, the roots should be frequently turned, while they remain in this stove, and the fires must be properly regulated. If some trials are made by fixing a good thermometer in the room, the necessary heat may be better ascertained than can be done any other way; but this will require to be greater at some times than at others, according as the roots are more or less succulent, or the weather more or less cold or damp; but it will always be better to have the heat rather less than over hot; for, though the roots may require a longer time to dry with a slow heat, yet the colour will be better.

When the roots are properly dried in this stove, they must be carried to the pounding-house, where they must be reduced to powder in the manner before related; but whether it is necessary to separate the krap from the gemeens, as is now practised by the Dutch, the consumers of Madder will be better judges than myself.

There has been some objections of late mentioned to the introducing, or rather retrieving the culture of Madder in England, which it may be proper here to

take notice of, lest they should have so much weight as to prevent many persons from engaging in it. The first which has been generally started is, that the land in this country is not so well adapted for growing Madder as that in Holland: to which I can with truth affirm, that there are vast tracts of land here much better adapted for producing Madder than the best land in Zealand; and from the experience which I have had of its growth, will produce a greater crop. Another objection which I have heard, was the labour in Holland being cheaper than in England. The Dutch will always undersell us, so consequently will maintain this branch of trade; but this is certainly a great mistake: for though the labourers employed in cultivating Madder may not earn so great wages as is generally paid in England, sure I am, that the difference between an expert English labourer and that of the best Dutchman, in the ploughing, hoeing, planting, &c. of Madder, is much greater than that of their pay; for I am sure a good English gardener or ploughman will do more business, and perform it better, in four days, than the best workman in Holland can do in six. What I now say is greatly within compass, from my own knowledge; so that, supposing we were to proceed in the same manner now practised by the Dutch, this could be no objection to the cultivating of Madder; but we shall soon find ways of performing the most laborious part, at much less expence, by means of the hoeing plough, which may be used to great advantage in the cultivation of Madder, whereby the expence will be much lessened; and, when once this is well established in England, there can be no doubt but that great improvements will be made both in the culture and method of preparing the commodity for use.

There has been objections made against farther trials of growing Madder, because some who have engaged in it have not succeeded: but in answer to this, it must be observed, that their ill success was owing to a want of skill. Some of them continued to plant repeated crops of Madder on the same spot of ground, till the roots became so small, as scarce to pay the expence of digging up; and here it is proper to observe, that Madder should not be planted on the same land, till after an interval of seven or eight years; during which interval the ground may be sown with any sort of grain, or kitchen vegetables, which it will produce to great advantage after Madder, because the land will be wrought so deep. The Dutch always sow grain upon their Madder ground in the intervals of four years, and have great crops from it; and they are obliged, from the scarcity of land fit for this purpose, to plant the same ground after an interval of four years; but, as we are not under the same necessity, it will be much better to stay eight years, for the roots of Madder are very similar to those of Asparagus, and draw much the same nourishment from the ground; and it is well known that, when Asparagus roots are dug up, which have been growing three years, if the same is planted with Asparagus again in a few years, it will not thrive equal to that which is planted on ground upon which Asparagus has not grown for several years; and this is always found to be the case even in kitchen-gardens near London, where, by the well working and frequent dunging the ground, it may be supposed changed in three or four years, more than the fields can possibly be in eight or ten.

Madder should not be planted in very rich dunged land, for in such there will be very large haulm, but the roots will not be in proportion; and, where there is much dung or sea-coal ashes, the Madder roots will be of a darker colour, as it will also where it is cultivated in the smoke of London, which is likewise the case with Liquorice; for that which grows in a sandy loam at a distance from London, is always much brighter and clearer than that which grows in the rich lands in the neighbourhood of London.

In Zealand the Madder is principally cultivated by

the kitchen-gardeners, who, in the change of their crops, do every fourth or fifth year plant the Madder upon the same ground again, in like manner as the gardeners in the neighbourhood of London plant Asparagus for forcing in winter upon hot-beds. And as they have public kilns in Holland for drying of the Madder roots, so they know the expence of manufacturing the commodity for sale, which renders the cultivation sure and easy to them.

If the cultivation of Madder is carried on properly in England, it will employ a great number of hands from the time harvest is over, till the spring of the year, which is generally a dead time for labourers, and hereby the parishes may be eased of the poor's rate, which is a consideration worthy of public attention.

RUBUS. Tourn. Inst. R. H. 614. tab. 385. Lin. Gen. Plant. 557. [This plant is so called, of the red colour of the fruit before it comes to maturity.] The Bramble or Raspberry-bush; in French, *Ronce*.

The CHARACTERS are,

The flower has a permanent empalement of one leaf, which is cut into five spear-shaped segments; it hath five roundish petals, and a great number of stamina which are inserted in the empalement, and are shorter than the petals, terminated by roundish compressed summits, with a great number of germen, having small hair-like styles on the side of the germen, crowned by a single permanent stigma. The germen afterward becomes a berry composed of many acini collected into a head, each having one cell, in which is contained one oblong seed.

This genus of plants is ranged in the fifth section of Linnæus's twelfth class, which contains those plants whose flowers have many stamina which are inserted in the empalement, and many styles.

The SPECIES are,

1. RUBUS (*Fruticosus*) foliis quinato-digitatis ternatisque, caule petiolisque aculeatis. Flor. Suec. 409. *Bramble or Blackberry with hand-shaped leaves, having five and three lobes, and the foot-stalk and branches prickly. Rubus vulgaris* five *Rubus fructu nigro*. C. B. P. 479. *The common Blackberry*.
2. RUBUS (*Cæsius*) foliis ternatis subnudis lateralibus bilobis caule aculeato. Hort. Cliff. 192. *Bramble with naked trifoliate leaves and a prickly stalk. Rubus repens fructu cæcio*. C. B. P. 479. *The Dewberry*.
3. RUBUS (*Idæus*) foliis quinato-pinnatis ternatisque, caule aculeato, petiolis canaliculatis. Flor. Suec. 408. *Bramble with winged leaves, having five and three lobes, a prickly stalk, and channelled foot-stalks. Rubus Idæus spinosis*. C. B. P. 479. *Prickly Raspberry*.
4. RUBUS (*Glabro*) foliis ternatis subtus tomentosis, caule glabro. *Raspberry with trifoliate leaves, which are woolly on their under side, and have a smooth stalk. Rubus Idæus lævis*. C. B. P. 479. *The smooth Raspberry*.
5. RUBUS (*Occidentalis*) foliis quinato-pinnatis ternatisque, caule aculeato, petiolis teretibus. Lin. Sp. Plant. 493. *Bramble with winged leaves having five and three lobes, a prickly stalk, and taper foot-stalks. Rubus Idæus fructu nigro, Virginianus*. Hort. Elth. 327. *Virginia Raspberry with a black fruit*.
6. RUBUS (*Odoratus*) foliis simplicibus palmatis, caule inermi multifolio multifloro. Hort. Cliff. 192. *Raspberry with single hand-shaped leaves, and an unarmed stalk having many leaves and flowers. Rubus odoratus*. Cornut. 153. *Sweet Canada Raspberry, commonly called flowering Raspberry*.
7. RUBUS (*Hispidus*) foliis ternatis nudis, caulibus petiolisque hispidus. Lin. Sp. Plant. 493. *Bramble with naked leaves growing by threes, and hairy stalks and foot-stalks*.
8. RUBUS (*Saxatilis*) foliis ternatis nudis, flagellis repentibus herbaceis. Flor. Suec. 411. *Bramble with naked trifoliate leaves, and creeping herbaceous stalks. Chamærubus saxatilis*. C. B. P. 110. *Dwarf Rock Bramble*.
9. RUBUS (*Arcticus*) foliis ternatis, caule inermi unifloro. Flor. Suec. 412. *Bramble with trifoliate leaves, and an unarmed stalk having one flower. Rubus humilis*,

R U B

lis, flore purpureo. Buxb. Cent. p. 13. *Dwarf Bramble with a purple flower.*

10. RUBUS (*Chamæmorus*) foliis simplicibus lobatis, caule unifloro. Flor. Suec. 413. *Bramble with single leaves having lobes, and a stalk bearing one flower.* Chamæmorus. Clus. Hist. 118. *The Dwarf Mulberry, or Cloudberry.*

11. RUBUS (*Dalibarda*) foliis simplicibus cordatis indivisis crenatis, scapo aphylo unifloro. Lin. Sp. Plant. 708. *Bramble with single, heart-shaped, undivided leaves, and one flower on each stalk.*

The first sort grows naturally on the side of banks, and in hedges, in most parts of England, so is not cultivated in gardens; this is so well known as to need no description. Of this there are the following varieties:

1. The common Bramble with white fruit, which was found in a hedge near Oxford by Mr. Jacob Bobart. The branches of this sort are covered with a light green bark; the leaves are of a brighter green than the common sort, and the fruit is white, but it seldom produces fruit in gardens.

2. The Bramble without thorns; this is in every respect like the first, but the branches and foot-stalks have no thorns.

3. The Bramble with the legant cut leaves; this differs from the first in the leaves, being finely cut.

4. The Bramble with double flowers; this differs from the first in having very double flowers, so is frequently planted in gardens for ornament.

5. The Bramble with variegated leaves. This is by some preserved in gardens, but is very apt to become plain, if planted in good ground.

These sorts are easily propagated by laying down their branches, which will put out roots at every joint very freely. They may be transplanted any time from September to March, and will grow in almost any soil or situation.

The second sort hath weaker trailing stalks than the first; the leaves are trifoliate, and the lobes are larger than those of the other; the fruit is smaller, the acini larger, and but few in each fruit, which are of a deeper black colour. This grows naturally in England, and is known by the title of Dewberry.

The third sort is the Raspberry, which grows naturally in the woods in the northern parts of England, but is cultivated in gardens for its fruit, which supplies the table at the season when they are ripe. There are two or three varieties of this, one with a red, and the other with a white fruit, and the third generally produces two crops of fruit annually; the first ripens in July, and the second in October, but those of the latter season have seldom much flavour. These are accidental varieties, but the fourth sort I believe to be a distinct species, for the leaves are trifoliate, larger than those of the common sort, woolly on their under side, and the branches and stalks have no thorns. This produces but few fruit, and those are small, which has occasioned its being neglected.

The Raspberry is generally propagated by suckers, though I should prefer such plants as are raised by layers, because they will be better rooted, and not so liable to send out suckers as the other, which generally produce such quantities of suckers from their roots, as to fill the ground in a year or two; and where they are not carefully taken off or thinned, will cause the fruit to be small, and in less quantities; especially when the plants are placed near each other, which is too often the case, for there are few persons who allow these plants sufficient room.

In preparing these plants, their fibres should be shortened; but the buds which are placed at a small distance from the stem of the plant, must not be cut off, because those produce the new shoots the following summer. These plants should be planted about two feet asunder in the rows, and four or five feet distance row from row; for if they are planted too close, their fruit is never so fair, nor will ripen so kindly, as when

R U D

they have room for the air to pass between the rows. The soil in which they thrive best, is a fresh strong loam, for in warm light ground they do not produce so great plenty of fruit, for they naturally grow in cold land and in shade; therefore when they are planted in a warm situation and a light soil, they do not succeed.

The season for dressing them is in October, at which time all the old wood that produced fruit the preceding summer, should be cut down below the surface of the ground, and the young shoots of the same year must be shortened to about two feet in length; then the spaces between the rows should be well dug, to encourage their roots; if you bury a very little rotten dung therein, it will make them shoot vigorously the summer following, and their fruit will be much fairer. During the summer season they should be kept clean from weeds, which, with the before-mentioned culture, is all the management they will require; but it is proper to make new plantations once in three or four years, because when the plants are suffered to remain long, they will produce few and small fruit.

The Virginian flowering Raspberry, is commonly propagated in the nurseries as a flowering shrub. The flowers of this sort are as large as small Roses, and there is a succession of them for two months or more, so that they make an agreeable variety during their continuance. This sort frequently produces fruit in England, which are not so large as those of the common sort, and have little flavour. These ripen in September or the beginning of October.

The Virginian Raspberry rises with purplish stalks a little higher than the common sort; the leaves are of a lucid green on their upper side, but hoary on their under; their foot-stalks are taper; the fruit is shaped like those of the common Blackberry, and are of a deep black when ripe; the fruit has little flavour, so the plants are never cultivated for their fruit here. It ripens late in autumn.

The eighth sort grows naturally upon rocky hills in the northern counties of England, and most of the northern parts of Europe. This hath trailing herbaceous stalks, which put out roots at their joints, whereby it propagates in plenty; the leaves are trifoliate, the lobes are large, and of a lucid green; the fruit are small, so not worth cultivating.

The ninth sort grows naturally in Norway, Sweden, and Siberia; this hath an upright stalk about three inches high, garnished with small trifoliate leaves; the stalk is terminated by one purple flower, which is succeeded by a small red fruit, having the scent and flavour of Strawberries. This plant grows naturally upon mossy bogs, so cannot be cultivated to any purpose on dry ground, and is preserved in a few gardens for the sake of variety.

The tenth sort grows naturally upon some of the highest hills in the north of England and Scotland, also upon high boggy places in the northern parts of Europe. This plant cannot be transplanted into gardens so as to thrive; the stalks rise about six or eight inches high, and are generally garnished with two lobed leaves, standing at a distance from each other. The stalk is terminated by a single flower, which is succeeded by a small black fruit, not much unlike that of the Dewberry, and is by some persons much esteemed; the red and black game feed much upon it in the season.

The eleventh sort grows naturally in Canada; it has a creeping herbaceous root, sending out trailing herbaceous stalks, which frequently put out roots; the leaves are for the most part composed of three heart-shaped lobes, which are veined and hairy; the flowers have five white petals: the flowers are male and female on the same plant, and the fruit is somewhat like the last.

RUDBECKIA. Lin. Gen. Plant. 878. Obeliscotheca. Vaill. Act. Par. 1720. Bobartia. Pet. Mus. Dwarf Sunflower, vulgò.

The

The CHARACTERS are,

It hath female and hermaphrodite florets inclosed in one common empalement, composed of two orders of leaves, the scales of which are plain, broad, and short. The rays or border of the flower is composed of female half florets, which are stretched out on one side like a tongue, and end with two or three indentures; these have germen sitting upon proper receptacles, but have neither style or stamina, and are barren. The hermaphrodite florets are tubulous, funnel-shaped, and indented in five parts at the brim. They have five short hair-like stamina in each, terminated by cylindrical summits, and a germen sitting in the common empalement, having a slender style crowned by a reflexed stigma, divided into two parts. The germen afterward become single, oblong, four-cornered seeds, crowned by their proper cup, which has four indentures.

This genus of plants is ranged in the third section of Linnaeus's nineteenth class, which includes the plants whose flowers are composed of hermaphrodite fruitful florets, and female barren half florets.

The SPECIES are,

1. *RUDBECKIA (Hirta)* foliis indivisis spatulato-ovatis, radii petalis emarginatis. Lin. Sp. Plant. 907. *Rudbeckia* with oval, spattle-shaped, undivided leaves, and the petals of the rays indented. *Chrysanthemum helenii* folio, umbone floris, grandiuicula prominente. Pluk. Alm. 99. tab. 242. *Corn Marygold* with an *Elecampane* leaf, and a large prominent middle to the flower, commonly called *Dwarf American Sunflower*.
2. *RUDBECKIA (Purpurea)* foliis lanceolato-ovatis alternis indivisis, petalis radii bifidis. Flor. Virg. 104. *Rudbeckia* with oval, spear-shaped, undivided leaves, placed alternate, and the petals of the ray bifid. *Chrysanthemum Americanum*, *doronici* folio, flore persici coloris, umbone magno prominente ex atro purpureo viridi & aureo fulgente. Pluk. Alm. 99. *American Corn Marygold* with a *Leopardsbane* leaf, a *Peach-coloured* flower, and a large prominent middle of a dark purple, green, and shining gold colour, commonly called *Dwarf Carolina Sunflower*.
3. *RUDBECKIA (Triloba)* foliis spatulatis, caulinis quibusdam trilobis, ramis indivisis. Hort. Upsal. 269. *Rudbeckia* with under leaves spattle-shaped, and the upper ones with three lobes. *Chrysanthemum cannabinum Virginianum* hirsutum, disco magno, petalis aureis radiato. Pluk. Alm. 100. tab. 22. fig. 2. *Virginian Hemp Agrimony*, with a large disk to the flower, and the petals of the rays of a gold colour.
4. *RUDBECKIA (Laciniata)* foliis inferioribus compositis acutè dentatis, caulinis simplicibus integris dentatisque. *Rudbeckia* with compound, indented, lower leaves, those upon the stalks single, entire, and indented. *Corona folis foliis amplioribus laciniatis*. Tourn. Inst. R. H. 490. *Sunflower* with large jagged leaves.
5. *RUDBECKIA (Quinata)* foliis omnibus quinatis, acutè dentatis exterioribus trilobatis. *Rudbeckia* with all the leaves composed of five lobes which are sharply indented, and the outer ones divided into three. *Corona folis foliis angustioribus laciniatis*. Tourn. Inst. R. H. 490. *Sunflower* with narrow jagged leaves.
6. *RUDBECKIA (Digitatis)* foliis inferioribus compositis, caulinis quinatis ternatisque, summis simplicibus. *Rudbeckia* with compound lower leaves, those on the stalks quinquefoliate and trifoliate, and the top ones single. *Obeiscotheca petalis florum perangustis longis, foliis digitatis, caule glabro ferrugineo*. Amman. *Sunflower* with long narrow petals to the flower, hand-shaped leaves, and a smooth iron-coloured stalk.
7. *RUDBECKIA (Angustifolia)* foliis oppositis integerrimis. Gron. Virg. 181. *Rudbeckia* with linear entire leaves placed opposite.

The first sort grows naturally in Virginia, and several other parts of North America. The root of this will continue four or five years, but unless there is care taken to shelter it in winter, the plants are sometimes destroyed by cold or too much wet. This sort sends out heads by which it may be propagated; the leaves are oblong, oval, and hairy; the stalks rise a foot and a half high, and have one or two leaves near the

bottom. The foot-stalk which supports the flower, is naked near a foot in length, and is terminated by one pretty large yellow flower, shaped somewhat like the Sunflower, from whence it was titled Dwarf Sunflower. The petals or rays of the flower are very stiff, and are slightly indented at their points; the middle or disk of the flower is very prominent, pyramidal, and of a dark purple colour. These flowers are of long duration; I have frequently observed one flower has continued in beauty near six weeks, and as the plants produce many flowers, so there is a succession of them on the same plant, from the middle of July till the frost puts a stop to them, which renders them more valuable. This sort will sometimes produce good seeds in England, when the seasons are very favourable; but they are generally propagated here by offsets or slips, unless when good seeds can be procured from America. The best time to separate the offsets is in the spring, because the plants continue to flower so late in autumn, as to render it impracticable to perform it till the spring, so that the slips will flower but weak the same year. The plants will live abroad in the open air through the winter, if they are planted in a dry soil and a warm situation; but it will always be prudent to shelter two or three plants under a common hot-bed frame in winter to preserve the kind, because in very severe winters they are often killed.

The second sort grows naturally in Carolina, and also in Virginia. This is a perennial plant like the former, but very rarely produces seeds in England; nor do the plants put out heads whereby it may be propagated like the other, so that it is at present not very common here. The leaves of this sort are longer and broader than those of the other, and are smooth, having three veins; the stalks which support the flowers are taller, and have two or three narrow leaves on each, which are placed alternate: on the top is one flower with long, narrow, Peach-coloured petals, which are reflexed; the middle or disk of hermaphrodite florets is very prominent, and of a dark purple colour, but the summits upon the stamina being of a gold colour, adds a lustre to the other. This sort may be treated in the same manner as the other, by sheltering of it in winter; it flowers at the same season, but the flowers are not of so long duration as those of the former.

The third sort grows naturally in several parts of North America; this is a biennial plant, which in warm summers perfects its seeds in England; the lower leaves of this sort are divided into three lobes, but those upon the stalks are undivided; they are hairy, and shaped like those of the first sort; the stalks branch out on their sides, and are better garnished with leaves than either of the other. The flowers are very like those of the first sort, but are smaller; the plants will live through the winter in the open air in mild seasons, and may be propagated by slips or heads; but the best way is to raise the plants from seeds, because those will flower much better than such as are procured by slips; the second year the seedling plants will flower, and produce ripe seeds.

The fourth sort grows naturally in most parts of North America, and has been long an inhabitant in the European gardens, where it was generally known by the title of Sunflower. The root of this is perennial, but the stalk is annual; the lower leaves are composed of five broad lobes, which are deeply cut into acute points, and some of them are jagged almost to the midrib; the outer lobe is frequently cut into three deep segments. The stalks rise seven or eight feet high, and divide upward into several branches; they are smooth, green, and garnished with single leaves, which are oval and heart-shaped; some of these are indented on their edges, others are entire. The foot-stalks which sustain the flowers are naked, and terminated by a single flower with yellow petals or rays, shaped like those of the Sunflower, but smaller. This does not produce seeds here, but is easily propagated by parting of the roots, in the same manner.

manner as the perennial Sunflower. It is very hardy in respect to cold, but loves a moist soil.

The fifth sort has a perennial root like the former, and is a native of the same country. This hath smooth green stalks, which rise higher than those of the former; the leaves are all composed of five lobes which are much narrower, and end with sharper points than those of the former, and are very acutely indented on their sides. The flowers are smaller, and the petals narrower than those of the former sort, but appear at the same season. It is equally hardy with the former, and may be propagated in the same way.

The sixth sort grows naturally in North America, and also in Siberia, from both which countries I have received the seeds. This hath a perennial root like the two former; the leaves at bottom are composed of seven or nine lobes, some of which are entire, and others are jagged to the midrib, they are of a dark green and smooth; the stalks rise six feet high, and divide into many branches. They are of a purple or iron colour, and are very smooth; these are garnished with leaves, which toward the bottom are hand-shaped, and composed of five lobes; higher up they have but three, and at the top the leaves are single. The flowers are smaller than those of the two former sorts, but are of the same shape and colour.

The seventh sort grows naturally in Virginia. This hath a perennial root; the stalks rise four or five feet high; the leaves are narrow, smooth, and placed opposite; the rays of the flower are long, yellow, and are twelve in number; the disk of male florets are of a dark red, and the scales of the empalement spread, and are almost awl-shaped.

These four last mentioned sorts may be propagated in plenty, by parting of their roots; the best time for this is in October, when the stalks will begin to decay; for if they are removed in the spring, they will not produce many flowers the same year. They love a moist soil, and should be allowed room, for if they are too near other plants, they will rob them of their nourishment and destroy them. They are proper furniture for large gardens, where they may be allowed room, or in walks round fields, because they require little culture.

RUELLIA. Plum. Nov. Gen. 12. tab. 2. Lin. Gen. Plant. 702.

The CHARACTERS are,

The flower has a permanent empalement of one leaf, which is cut into five narrow acute segments at the top, which are erect. It has one petal, with a tube the length of the cup, which spreads and inclines at the neck, but the brim spreads open, where it is cut into five segments, the two upper being large and reflexed. It hath four stamina situated in the spreading part of the tube, connected in pairs, terminated by short summits, and a roundish germen supporting a slender style, crowned by a bifid stigma. The germen afterward becomes a taper capsule, pointed at each end, having two cells, inclosing roundish compressed seeds.

This genus of plants is ranged in the second section of Linnæus's fourteenth class, which includes those plants whose flowers have two long and two short stamina, and the seeds are included in a capsule.

The SPECIES are,

1. **RUELLIA** (*Tuberosa*) foliis ovatis crenatis, pedunculis bifloris. *Ruellia with oval crenated leaves, and foot-stalks bearing two flowers.* Ruellia humilis, flore cæruleo, asphodeli radice. Plum. Nov. Gen. 12. *Dwarf Ruellia, with a blue flower and an Asphodel root.*
2. **RUELLIA** (*Strepens*) foliis petiolatis, floribus verticillatis subsessilibus. Hort. Upsal. 178. *Ruellia with leaves having foot-stalks, and flowers growing in whorls, sitting close to the stalks.* Ruellia strepens, capitulis comosis. Hort. Elth. 328. *Snapping Ruellia with hairy beads.*
3. **RUELLIA** (*Clandestina*) foliis petiolatis, pedunculis longis subdivisis nudis. Lin. Hort. Upsal. 179. *Ruellia with leaves having foot-stalks, and long naked foot-stalks to the flowers, which are divided.* Ruellia cap-

fulis teretibus. Hort. Elth. 328. *Ruellia with taper capsules.*

4. **RUELLIA** (*Crispa*) foliis subcrenatis lanceolato-ovatis, capitulis ovatis, foliosis hispida. Lin. Sp. Plant. 635. *Ruellia with oval spear-shaped leaves which are somewhat crenated, oval pods, and prickly, hairy, small leaves.*

5. **RUELLIA** (*Paniculata*) foliis integerrimis pedunculis dichotomis lateralibus calycibus sessilibus, lacinia suprema majore. Lin. Sp. Plant. 885. *Ruellia with entire leaves, a forked stalk, and the upper segment of the flower large.* Speculum veneris majus impatiens. Sloan. Hist. Jam. 1. p. 158.

The first sort grows naturally in many of the islands in the West-Indies; the roots of this are composed of many swelling fleshy tubers, which run deep into the ground, and are like those of the Day Lily, but smaller. The stalk rises about four or five inches high, and sends out two or three short side branches, which are garnished with leaves placed opposite; some of these are small and shaped like a spatula, others are much larger; they have short foot-stalks, and are a little crenated on their edges. The flowers are produced on the side, and at the end of the stalk; those on the side have two flowers upon each foot-stalk, which come out opposite at each joint, but those at the top sustain three. The flowers have narrow tubes about an inch long, then they spread out to a sort of bell-shape, and at the top they are cut into five obtuse segments, which are large and spread open; they are of a fine blue, but of short duration, each flower seldom lasting in beauty one day; after the flower fades, the germen becomes a taper pod one inch and a half long, having two cells, which, when ripe, burst with a touch, and cast out the seeds to a distance. It flowers in July, and the seeds ripen the beginning of September.

The second sort grows naturally in Carolina; the root of this is fibrous and perennial; the stalks rise about a foot high, they are four-cornered, and have two longitudinal furrows, one on each side; the joints are three or four inches asunder, at each stand two oval leaves upon very short foot-stalks. The flowers come out from the wings of the leaves on each side, two or three rising from the same point, sitting very close to the stalks; they are small and of a pale purple colour, but are very fugacious; they open early in the morning, but are gone by ten or eleven o'clock in the forenoon; these are succeeded by short taper pods, surrounded by the hairy segments of the empalement. It flowers and perfects its seeds about the same time as the former.

The third sort grows naturally in the West-Indies; this hath a perennial root, composed of many fleshy fibres; the leaves and stalks lie close to the ground; the stalks grow five or six inches high; the leaves are placed by pairs at each joint; they are two inches long, and one inch and a quarter broad, standing upon foot-stalks half an inch long. The foot-stalks which sustain the flowers are naked, and divide into two smaller, each sustaining one small purple flower, which is very fugacious; their empalements are cut into very narrow segments to the bottom. After the flowers are past, the germen becomes a taper capsule about an inch long, including roundish compressed seeds.

The fourth sort grows naturally in both Indies; I received the seeds of this from Carthagenia in New Spain. This hath a ligneous creeping root; the stalks rise about five or six inches high, they are single, taper, and jointed; the leaves are oval, spear-shaped, and have very short foot-stalks; they are a little waved on their edges, are hairy and curled. The flowers are produced from the side of the stalk at their joints; these sustain one small yellow flower, coming out between rough, hairy, small leaves. It flowers in July, and the seeds ripen in September.

The fifth sort hath a perennial root; the stalks rise four or five feet high, are very diffused and forked, and garnished with oblong, oval, entire leaves placed

R U M

opposite, standing on short foot-stalks which are hairy; the flowers are produced at the divisions of the stalks; they are small, purple, and of short duration.

These plants are propagated by seeds, which must be sown early in the spring in pots filled with light rich earth, and plunged into a moderate hot-bed; and when the plants come up, they must be transplanted each into a separate small pot filled with rich earth, and plunged into a hot-bed of tanners bark, where they must be shaded from the sun until they have taken new root; after which time they must have free air admitted to them every day in warm weather, and be constantly watered three or four times a week during the summer season. If the plants thrive well, those of the first and third sorts will produce flowers the July following, and will perfect their seeds in August; but the roots will continue, provided they are plunged into the bark-bed in the stove, and kept in a moderate temperature of heat.

The second sort is not a plant of long continuance, seldom abiding longer than two years; but if it is treated in the same manner as the two other, it will ripen seeds the second year, so may be propagated easily.

The fourth sort does not so constantly produce seeds as the three others, so it is not so common in England at present. This requires the same treatment as the other sorts.

If the seeds of these sorts are permitted to scatter, as their pods discharge them with a violent spring into the neighbouring pots, the plants will come up without care, so may be transplanted into pots filled with fresh loamy earth, and plunged into the tan-bed.

RUMEX. Lin. Gen. Plant. 407. *Lapathum*. Tourn. Inst. R. H. 504. tab. 287. Dock.

The CHARACTERS are,

The empalement of the flower is permanent; composed of three obtuse reflexed leaves. The flower has three petals which are larger than the empalement, to which they are very like. It hath six short hair-like stamina, terminated by erect twin summits, and a three-cornered germen supporting three hair-like reflexed styles, thrusting out of the clefts of the petals, crowned by large jagged stigmas. The germen afterward becomes a three-cornered seed, included in the petals of the flower.

This genus of plants is ranged in the third section of Linnæus's sixth class, which includes those plants whose flowers have six stamina and three styles; to which he has joined the *Acetosa*, or *Sorrel* of Tournefort, whose characters agree with those of the Dock; but as in the gardens and shops they are distinguished under different titles, I have separated the *Sorrel* from the Docks, and have placed them under their old title of *Acetosa*.

The SPECIES are,

1. **RUMEX** (*Patientia*) floribus hermaphroditis, valvulis integerrimis, foliis oblongo-lanceolatis. Dock with hermaphrodite flowers having entire valves, and oblong spear-shaped leaves. *Lapathum hortense*, folio oblongo, live secundum Dioscoridis. C. B. P. 114. Garden Dock with an oblong leaf, commonly called *Patientia*, or *Patientia Rhubarb*.
2. **RUMEX** (*Alpinum*) floribus hermaphroditis, valvulis integerrimis graniferis, foliis cordatis obtusis. Rumex with hermaphrodite flowers having entire valves bearing grains, and obtuse heart-shaped leaves. *Lapathum folio rotundo Alpinum*. J. B. 2. 987. Round-leaved Alpine Dock, called *Monks Rhubarb*.
3. **RUMEX** (*Aquaticus*) floribus hermaphroditis pedicellatis, foliis lanceolatis longissimis. Rumex with hermaphrodite flowers growing upon small foot-stalks, and the longest spear-shaped leaves. *Lapathum aquaticum*, folio cubitali. C. B. P. 116. Water Dock with a leaf a cubit long, commonly called *Herba Britannica*.
4. **RUMEX** (*Acutus*) floribus hermaphroditis, valvulis dentatis graniferis, foliis cordato-oblongis acuminatis. Hort. Cliff. 138. Rumex with hermaphrodite flowers, indented grain-bearing valves, and oblong heart shaped leaves. *Lapathum folio acuto, plano*. C. B. P. 115. Plain sharp-pointed Dock.

R U M

5. **RUMEX** (*Crispus*) floribus hermaphroditis, valvulis integris graniferis, foliis lanceolatis undulatis acutis. Lin. Sp. Plant. 335. Rumex with hermaphrodite flowers, entire grain-bearing valves, and acute, spear-shaped, waved leaves. *Lapathum folio acuto, crispo*. C. B. P. 115. Curled sharp-pointed Dock.
6. **RUMEX** (*Sanguineus*) floribus hermaphroditis, valvulis integerrimis, unica granifera foliis cordato-lanceolatis. Hort. Cliff. 138. Rumex with hermaphrodite flowers, entire valves, one only bearing a seed, and heart-formed spear-shaped leaves. *Lapathum folio acuto rubente*. C. B. P. 114. The bloody Dock.
7. **RUMEX** (*Aureus*) floribus hermaphroditis verticillatis, valvulis acutè dentatis, foliis lanceolatis. Rumex with hermaphrodite flowers growing in whorls, acutely indented valves, and spear-shaped leaves. *Lapathum folio acuto, flore aureo*. C. B. P. 114. Sharp-pointed Dock with a golden flower.
8. **RUMEX** (*Obtusifolius*) floribus hermaphroditis, valvulis dentatis, foliis cordato-oblongis, obtusiusculis crenulatis. Lin. Sp. 335. Rumex with hermaphrodite flowers, indented valves, and blunt, oblong, heart-shaped leaves. *Lapathum vulgare, folio obtuso*. J. B. 2. 985. Common broad-leaved Rumex, or *Butter Dock*.
9. **RUMEX** (*Pulcher*) floribus hermaphroditis, foliis ly-ratis. Guct. Stamp. 1. p. 7. Rumex with hermaphrodite flowers, and lyre-shaped leaves. *Lapathum pulcrum Bononiense sinuatum*. J. B. 2. p. 988. The Fiddle Dock.
10. **RUMEX** (*Maritimus*) floribus hermaphroditis, valvulis dentatis graniferis, foliis linearibus. Lech. Scan. 26. Rumex with hermaphrodite flowers, indented grain-bearing valves, and linear leaves. *Lapathum aquaticum luteolæ folio*. Bocc. Mus. 2. tab. 184. Water Dock with a Weld leaf.
11. **RUMEX** (*Chalepensis*) floribus hermaphroditis pedunculis longioribus, valvulis profundè dentatis, foliis cordato-oblongis. Rumex with hermaphrodite flowers growing upon longer foot-stalks, valves which are deeply indented, and oblong heart-shaped leaves. *Lapathum chalepense folio acuto, seminum involucris profundè dentatis*. Mor. Hist. 2. 58. Aleppo Dock with an acute leaf, and the covers of the seeds deeply indented.
12. **RUMEX** (*Egyptiacus*) floribus hermaphroditis, valvulis trifido setaceis, unica granifera. Hort. Upsal. 89. Rumex with hermaphrodite flowers, and bristly three-pointed valves, one of which bears the seed. *Lapathum Egyptiacum annuum, parietariæ folio, capsulâ seminis, longius barbata*. Hort. Piss. Annual Egyptian Dock, with a Pellitory leaf, and long beards to the seed-vessels.
13. **RUMEX** (*Lunaria*) floribus hermaphroditis valvulis lævibus, caule arboreo, foliis subcordatis. Vir. Cliff. 32. Rumex with hermaphrodite flowers, smooth valves, a tree-like stalk, and leaves which are almost heart-shaped. *Acetosa arborescens subrotundo folio, ex insulis fortunatis*. Pluk. Phyt. tab. 252. fig. 3. Tree Sorrel from the Fortunate Islands, with a roundish leaf.
14. **RUMEX** (*Bucephalophorus*) floribus hermaphroditis, valvulis dentatis nudis planis reflexis. Hort. Upsal. 90. Rumex with hermaphrodite flowers, and plain, naked, indented, reflexed valves. *Acetosa ocymi folio, Neapolitana*. C. B. P. 114. Naples Sorrel with a Basil leaf.
15. **RUMEX** (*Vesicarius*) floribus hermaphroditis geminatis, valvularum alis maximis membranaceis reflexis, foliis indivisis. Hort. Cliff. 130. Rumex with hermaphrodite flowers growing by pairs, very large membranaceous wings to the valves which are reflexed, and undivided leaves. *Acetosa Americana foliis longissimis pediculis donatis*. C. B. P. 114. American Sorrel, with very long leaves having foot-stalks.
16. **RUMEX** (*Roseus*) floribus hermaphroditis distinctis, valvularum alis maximis membranaceis reflexis, foliis eros. Flor. Leyd. Prod. 230. Rumex with hermaphrodite flowers growing upon distinct spikes, very large membranaceous wings to the valves, and leaves appearing as if bitten. *Acetosa Egyptia roseo seminis involucro, folio lacero*. Lipp. Egyptian Sorrel with a Rose-coloured cover to the seed, and a torn leaf.

The

R U M

The first sort was formerly much more cultivated in the English gardens than at present; this has been generally used for the Monks Rhubarb, and has been thought the true, but others suppose the second sort should be used as such; the herb was formerly used in the kitchen, by the title of Patience. The root is large, and divides into many thick fibres which run downward; their outer cover is brown, but they are yellow within, with some reddish veins; the leaves are broad, long, and acute-pointed; their foot-stalks are of a reddish colour; the stalks rise from four to six feet high, and divide toward the top into several erect branches, which are garnished with a few narrow leaves, terminating with spikes of large staminate flowers. These appear in June, and are succeeded by pretty large three-cornered seeds whose coverings are entire, which ripen in autumn.

The second sort grows naturally on the Alps, but has been long cultivated in the English gardens. This hath large roots, which spread and multiply by their offsets; they are shorter and thicker than those of the first sort, of a very dark brown on their outside, and yellow within. The leaves are of the round heart-shape, about nine inches long, and as much in breadth near their base, having pretty long foot-stalks. The stalks rise from two to three feet high; they are very thick, and have a few small roundish leaves on the lower part, but the upper part closely garnished with spikes of white flowers, standing erect, close to the stalks. These appear the latter end of May, and are succeeded by large triangular seeds, which ripen in August.

The third sort grows naturally in ponds, ditches, and standing waters, in many parts of England; this is supposed to be the Britannica of the ancients. It hath large roots which strike deep into the loose mud, sending out leaves which are three feet long, and four inches broad in the middle, drawing to a point at each end. The stalks rise four feet when growing in water, but in dry land not more than two; these are garnished with narrow leaves among the spikes of flowers, to the top. The flowers stand upon slender foot-stalks which are reflexed; they are of an herbaceous colour, appear in June, and the seeds ripen in autumn.

The fourth sort grows naturally in moist places in many places of England; this is the Oxylapathum of the shops, which is directed by the College to be used in medicine; but the markets are supplied with roots of the common Docks, which are indifferently gathered by those who collect them in the fields, where the eighth sort is much more common than this. The roots of this sort are slender and run down-right, sending out a few small fibres; the stalks rise about two feet high, which are garnished with leaves below, about four inches long, and one and a half broad in the middle; they are rounded at their base, where they are slightly indented, but end in acute points; they are plain, and slightly crenated on their edges. From the joints of the stalk come out alternately slender long foot-stalks, which sustain the spikes of flowers, which grow in small whorls round the stalks, at about an inch distance; these have scarce any leaves upon the foot-stalks between the whorls of flowers, so may be easily distinguished from the small Water Dock, which has many. This flowers in June, and the seeds ripen in autumn.

The fifth sort is more commonly found growing naturally about London than the fourth; the leaves of this are much longer than those of the former, and are indented on their sides, which are also waved; the stalks rise about the same height as those of the former. The spikes of flowers from the side are shorter, and closer garnished with flowers on pretty long foot-stalks; the covering of the seed is entire. It flowers and seeds about the same time with the former.

The sixth sort is very like the fourth in appearance, but the leaves have deep blood-coloured veins, and some small spots of the same on their surface; the stalks are red, and rise about the same height as the

R U M

fourth, but the covering of the seed is entire; whereas those of the fourth are indented, so may be readily distinguished. It grows naturally in many parts of England.

The seventh sort grows naturally in several parts of England; this is a biennial plant, which perishes soon after the seeds are ripe; the stalks rise near two feet high; they are of a deep purple colour, and are garnished with spear-shaped leaves toward the bottom, which are four inches long, and almost one broad in the middle, but those on the upper part of the stalk are very narrow, and not more than two inches long; the spikes of flowers come out from the sides of the stalks alternately. The flowers grow in thick whorls which sit close to the stalks; these are of a bright yellow colour, and the covers of the seeds are sharply indented.

The eighth sort is the most common Dock by the sides of roads and banks in every part of England; the leaves of this sort are broad and rounded at their points, though some of them end more acutely than others; they are near a foot long, and five inches broad toward their base, having many transverse veins running from the midrib to their borders. The stalks rise from two to three feet high, branching out on their sides, having a few leaves on their lower part of the same shape with the other, but smaller. The flowers grow in whorls, sitting very close to the stalks; some plants have indented coverings to their seeds, and others have entire coverings; both these are frequently found intermixed, so that I doubt of their being distinct species. The leaves of this Dock were formerly much used for wrapping up of butter, and from thence the plant was called Butter Dock.

The ninth sort grows naturally in many places near London; this is a biennial plant, which perishes soon after the seeds are ripe. The stalks of this rise about a foot high, and branch out from the bottom; the leaves grow near the root; they are about two inches and a half long, and are hollowed on their sides, so as to resemble the sides of a fiddle; the stalks are generally bent at their joints. The flowers grow in whorls round the stalks, to which they sit very close; they are hermaphrodite; the covers of the seeds are sharply indented.

The tenth sort is sometimes found growing naturally in England, upon places where the water has stood in winter. This seldom rises more than five or six inches high, but divides into two or three branches; the leaves are about three inches long, and a quarter of an inch broad; they are smooth, and stand upon short foot-stalks. The flowers grow in whorls round the branches, to which they sit very close; these are succeeded by small triangular seeds, having indented covers.

The eleventh sort came originally from Aleppo; this is a biennial plant; the leaves are nine or ten inches long, smooth, and of a light green; they are three inches broad at their base, where they are indented, and end in acute points. The stalks rise from two to three feet high, sending out many branches from their sides, which are garnished with large whorls of herbaceous flowers, standing upon pretty long foot-stalks; these are succeeded by three-cornered seeds, whose coverings are deeply indented.

The twelfth sort grows naturally in Egypt; this is an annual plant; the stalk rises about ten inches high, sending out a few horizontal branches toward the bottom; the leaves are about two inches long, and half an inch broad at the broadest part. The flowers grow in whorls round the stalks, they are very small, and the hair-like beards which adhere to the covering of the seed being long, obscure the flowers, so they are scarce visible to the naked eye.

All these sorts of Docks rise easily from seeds, and if introduced into a garden, will become troublesome weeds, if their seeds are permitted to scatter; therefore few persons care to propagate any of them, except the two first sorts, which are cultivated for their use in medicine. The seeds of all the Docks should be sown

sown in autumn soon after they are ripe, for those seeds which are sown in the spring rarely grow the same year: when the plants come up, they will require no other care but to thin them where they are too close, and keep them clean from weeds. They all delight in a moist rich soil.

The thirteenth sort is commonly known among the gardeners by the title of Sorrel-tree. This came originally from the Fortunate, or Canary Islands, but has been long an inhabitant in some English gardens; it rises with a ligneous stalk ten or twelve feet high, covered with a smooth brown bark, sending out many slender branches; these are garnished with smooth, roundish, heart-shaped leaves two inches long, and an inch and a half broad, standing alternately upon pretty long foot-stalks. The flowers come out in loose panicles toward the end of the branches; they are of an herbaceous colour, and are sometimes succeeded by triangular seeds with smooth covers, but they rarely ripen in England. This plant is easily propagated by cuttings, which may be planted in any of the summer months, in a bed of loamy earth, and shaded from the sun until they have taken pretty good root; then they should be taken up, and planted in pots filled with kitchen-garden earth, placing them in the shade till they have taken new root; after which they may be moved to a sheltered situation, and placed with other hardy green-house plants till autumn, when they must be removed into the green-house, and treated in the same way as other hardy kind of plants, which only want protection from frost.

The fourteenth sort is a low annual plant, which grows naturally in Italy and Spain; this is generally found on swampy moist ground; the stalks are slender, branching at the bottom, and rise about four inches high; the lower part is garnished with small, oval, succulent lobes; their upper part is furnished with small herbaceous flowers growing in whorls, and have no leaves between them; they are succeeded by small seeds, whose covers are sharply indented and reflexed. These appear in June, and the seeds ripen in August, which, if permitted to scatter, will furnish a supply of young plants the following spring; or if the seeds are then sown, the plants will come up the following spring, and require no other care but to thin them, and keep them clean from weeds.

The fifteenth sort is an annual plant; this hath pretty thick succulent stalks, which rise a foot high, and divide into many branches; the leaves are of the round heart-shape and undivided, having very long foot-stalks. The flowers grow in loose spikes at the end of the branches; these are herbaceous, and are succeeded by large covers to the seeds, which are inflated, and have broad membranaceous borders; the seeds are triangular, and ripen in autumn.

The sixteenth sort grows naturally in Egypt; this is also an annual plant, whose stalks rise a foot and a half high, dividing upward into several branches; the stalks are garnished with arrow-pointed leaves about three inches long, whose sides are irregularly torn, as if they had been gnawed by insects; they stand upon pretty long foot-stalks, and have smooth surfaces; the flowers are disposed in loose spikes; some spikes have only male flowers, and others have all hermaphrodite flowers, and some plants have only male, and others hermaphrodite flowers. The latter are succeeded by triangular seeds, inclosed in large inflated covers of a deep red colour, having membranaceous borders. The seeds of this ripen in autumn.

The seeds of both these sorts grow very freely, if sown in a bed of light earth in the spring, where the plants are designed to remain. When they come up, they will require no other care but to keep them clean from weeds, and thin them where they are too close.

RUSCUS. Tourn. Inst. R. H. 79. tab. 15. Lin. Gen. Plant. 1008. [so called of rusticus, because rough and prickly. It is also called Laurus, because fit for the making of Laurel garlands; and Alexan-

drina, from one of the sorts growing in Alexandria.] Knee-holly, or Butcher's-broom; in French *Houx-frelon*.

The CHARACTERS are,

It hath male and female flowers in distinct plants; the male flowers have erect spreading empalements, composed of six oval convex leaves, whose borders are reflexed; they have no petals, but have an oval nectarium the size of the empalement, which is erect and inflated, opening at the mouth; they have no stamina, but each has three spreading summits, sitting on the top of the nectarium, which are joined at their base. The female flowers have empalements but no petals, and nectariums like the male: they have no stamina, but have an oblong oval germen hid within the nectarium, supporting a cylindrical style, crowned by an obtuse stigma, standing above the mouth of the nectarium. The germen afterward becomes a globular berry with two or three cells, inclosing two globular seeds. This genus of plants is ranged in the twelfth section of Linnæus's twenty-second class, which contains the plants which are male and female in distinct plants, and the stamina or summits are joined together.

The SPECIES are,

1. *Ruscus (Aculeatus) foliis supra floriferis nudis.* Hort. Cliff. 465. *Ruscus with leaves which bear flowers on their upper side, and are naked.* *Ruscus myrtifolius aculeatus.* Tourn. Inst. 79. *Knee-holly, or Butcher's-broom, with prickly Myrtle leaves.*
2. *Ruscus (Hypophyllum) foliis subtus floriferis nudis.* Hort. Cliff. 465. *Ruscus with leaves which bear flowers on the under side of the leaves, which are naked.* *Ruscus latifolius, fructu folio innascente.* Tourn. Inst. 79. *Butcher's-broom with broad leaves, upon which the fruit grows.*
3. *Ruscus (Hypoglossum) foliis subtus floriferis sub foliolo.* Hort. Cliff. 465. *Ruscus with flowers under the leaves.* *Ruscus angustifolius, fructu folio innascente.* Tourn. Inst. 79. *Butcher's-broom with narrow leaves, and fruit sitting upon the leaves.*
4. *Ruscus (Racemosus) racemo terminali hermaphrodite.* Hort. Cliff. 469. *Ruscus with hermaphrodite flowers in long bunches terminating the stalks.* *Ruscus angustifolius, fructu summis ramulis innascente.* Tourn. Inst. 79. *Butcher's-broom with narrow leaves, and fruit growing at the top of the branches.*
5. *Ruscus (Trifoliatum) foliis ternis ovatis acuminatis, supra floriferis nudis.* *Ruscus with oval acute-pointed leaves which are placed by threes, and flowers on their upper side.*
6. *Ruscus (Flexuosus) foliis ovatis acuminatis, supra floriferis nudis, caulibus flexuosis.* *Ruscus with acute-pointed leaves bearing flowers on their upper side, and flexible stalks.* *Ruscus latifolius major fructu folio innascente.* Michel. *Greater broad-leaved Ruscus with fruit sitting upon the leaf.*
7. *Ruscus (Androgynus) foliis margine floriferis.* Hort. Cliff. 464. *Ruscus with flowers growing on the borders of the leaves.* *Ruscus latifolius & foliorum sinu florifer & fructifer.* Hort. Elth. 532. tab. 250. *Broad-leaved Ruscus, with flowers and fruit growing on the edges of the leaves.*
8. *Ruscus (Frutescens) caule fruticoso ramoso, foliis lanceolatis rigidis, floribus pedunculatis terminalibus.* *Ruscus with a shrubby branching stalk, spear-shaped stiff leaves, and flowers growing upon foot-stalks terminating the branches.* *Ruscus latifolius frutescens, floribus racemosis rubris.* Houst. MSS. *Shrubby broad-leaved Ruscus, with branching red flowers.*

The first sort is very common in the woods in divers parts of England, and is rarely cultivated in gardens. The roots of this kind are sometimes used in medicine, and the green shoots are cut, bound into bundles, and sold to the butchers, who use it as beams to sweep their blocks, from whence it had the name of Butcher's-broom. It is also called by some Knee-holly.

This hath roots composed of many thick white fibres, which strike deep in the ground, and twine about each other, from which arise several stiff green stalks,

stalks, which rise about three feet high, sending out from their side several short branches, which are garnished with stiff, oval, heart-shaped leaves, placed alternately on every part of the stalk; they are about half an inch long, and one third of an inch broad near their base, ending with sharp prickly points. The flowers are produced on the upper side of the leaves just in the middle; these are male in some, and female in other plants; they are small, and cut into six parts, of a purple colour, sitting close to the midrib; they appear in June, and the female flowers are succeeded by berries almost as large as Cherries, of a sweetish taste, which ripen in winter, when they are of a beautiful red colour.

As this plant grows wild in most parts of England, it is rarely admitted into gardens; but if some of the roots are planted under tall trees in large plantations, they will spread into large clumps; and as they retain their leaves in winter, at that season, they will have a good effect. The seeds of this plant generally lie a year in the ground before they vegetate, and the plants so raised are long before they arrive to a size enough to make any figure, so it is not worth while to propagate them that way, especially as the roots may be easily transplanted from the woods. The roots and seeds of this plant have been used in medicine; the roots are aperitive, and esteemed good for removing obstructions; the seeds are an ingredient in the composition of the benedicta laxativa: the young shoots of this plant in the spring are sometimes gathered and eaten by the poor like those of Asparagus; the branches of this plant, with their ripe fruit upon them, are frequently cut, and put into basins of sand, mixing them with the stalks of ripe seeds of male Piony, and those of the wild Iris or Gladwyn, which together make a pretty appearance in rooms, at a season of the year when there are few flowers, and these will continue a long time in beauty.

The second sort grows naturally in the mountainous parts of Italy, but is preserved for the sake of variety in many English gardens. The roots of this have large knotty heads, with long thick fibres like those of the former sort, from which arise many tough limber stalks near two feet high; these are garnished by stiff, oblong, oval leaves ending in points, which are more than two inches long and almost one broad; they are placed alternately on the stalks; the flowers are produced on the under surface of the leaves near the middle, sitting close to the midrib; they are small, and of an herbaceous white colour; the female flowers are succeeded by small red berries about the size of those of Juniper. This flowers in July, and the seeds ripen in winter.

It stands in most dispensaries among the plants used in medicine, and has been commended for opening obstructions of the kidneys, and to provoke urine.

The third sort grows naturally upon shady mountains in Italy, Hungary, and other parts of Europe. The root of this is composed of many thick fibres like those of the former, from which arise many tough limber stalks which are about ten inches high, garnished with spear-shaped leaves about three inches long and one broad in the middle, drawing to a point at both ends; they have several longitudinal veins, which run from the foot-stalk to the point, diverging from the midrib in the middle, but join again at the point; the leaves are for the most part alternate, but sometimes they are opposite. On the middle of the upper surface of these, comes forth a small leaf of the same shape; and at the same point, from the bosom of the small leaves, come out the flowers, which are of a pale yellow colour. The female flowers are sometimes succeeded by berries almost as large as those of the first sort, which ripen in winter, and are red. This is sometimes called *Bislingua*, or *Double Tongue*, from the leaves growing one out of another. It stands in dispensaries as a medicinal plant, but is seldom now used.

The fourth sort grows naturally in the Archipelago, but is frequently planted in the English gardens; it

is called *Laurus Alexandrina*, i. e. *Alexandrian Bay*; and is supposed to be the plant with which the ancients crowned their victors and poets. The stalks of this being very pliable, may be easily wrought into coronets for this purpose; and the leaves of this plant, having a great resemblance to those which are represented on the antient busts, seem to confirm this opinion.

The roots of this are like those of the former species; the stalks are slender, and much more pliable; they rise about four feet high, and send out many side branches, which are garnished with oblong acute-pointed leaves about two inches long, and one-third of an inch broad, rounded at their base, but end in acute points; they are smooth, and of a lucid green, placed alternately, and sit close to the branches. The flowers are produced in long bunches at the end of the branches; these are hermaphrodite, of an herbaceous yellow colour, and are succeeded by berries like those of the first sort, but smaller, which ripen in winter.

The fifth sort grows naturally in Zant, and some of the other islands in the Morea. The roots of this are like those of the former sorts; the stalks rise about two feet high, they are slender, pliable, and garnished with oval leaves placed by threes round the stalk; they are about two inches long, and one broad, rounded at both ends, terminating in acute points, and have several longitudinal diverging veins running from the foot-stalk to the point. The flowers grow on the under side of the leaves, fastened to the midrib; they are naked, and have pretty long foot-stalks; the segments or petals are very narrow; the fruit I have not seen, so can give no account of it.

The sixth sort grows naturally in Italy, where it was discovered by Signior Micheli of Florence. The roots of this are much longer than those of the first sort; the stalks rise near five feet high; they are very pliant, send out several side branches their whole length, which are garnished with stiff oval leaves ending in acute points; they are one inch long, and half an inch broad. The flowers are produced on the upper surface of the leaves, sitting close to the midrib; they are small, and of an herbaceous white colour. These are succeeded by berries which are smaller than those of the first sort, and are of a pale red when ripe.

All these sorts are very hardy, and will thrive in almost any soil or situation, so are very proper for planting round the verges of close woods, or under large trees in wilderness quarters; for, as they are always green, they make a good appearance in winter, after the deciduous trees have cast their leaves; they are easily propagated by parting of their roots. The best time for this is in autumn; but, when this is performed, the roots should not be divided into small parts, because that will weaken them so much, that they will make but little figure, until they have had two or three years growth; they may also be propagated by sowing of their seeds, but this is a very tedious method, so is seldom practised.

The seventh sort grows naturally in the island of Madeira; this sends out pliant stalks, which rise seven or eight feet high, and have several short branches proceeding from their sides, which are garnished with stiff leaves about two inches long, and one broad toward their base, where they are rounded to the foot-stalk, but end in acute points; they have a great number of longitudinal veins running from the foot-stalk to the point. The flowers are produced in clusters on the edges of the leaves; they are white, and are succeeded by berries of a yellowish red colour, not so large as those of the first sort.

This sort is tender, and must therefore be planted in pots filled with fresh earth, and in winter removed into the green-house, but it should be placed where it may have free air in mild weather; for it only requires to be screened from frost, and in the summer it must be set abroad with other hardy green-house plants. With this management the plants will send forth stems six or eight feet high, furnished with

R U T

leaves from bottom to top, and in June will be closely set with flowers upon their edges, which make a very beautiful and odd appearance, and renders it worthy of a place in every good collection of plants. This is also propagated by parting the roots as the former, which should not be done very often; because, if the roots are not permitted to remain some time to get strength, they will produce but weak shoots, and very few flowers; and in the strength of their shoots and number of flowers, the greatest beauty of these plants consist. This sort grows plentifully at Madeira, from whence the seeds may be procured; but these commonly lie in the ground a year before the plants come up, so should be sown in pots filled with fresh earth, and placed under a hot-bed frame in winter to screen the seeds from the frost, and the following spring the plants will appear.

The eighth sort was discovered by the late Dr. Houttoun, growing naturally at Carthagera in New Spain; this rises with shrubby stalks eight or ten feet high, which divide into many branches, and are garnished with stiff spear-shaped leaves three inches long, and one broad in the middle, ending in acute points; they are sometimes ranged in whorls round the stalks, and at others they are opposite. The flowers are produced in loose bunches at the end of the branches, standing upon slender foot-stalks; they are small, of a red colour, and shaped like those of the first sort.

This plant is tender, so must be kept in a stove during the winter, otherwise it will not live in England.

R U T A. Tourn. Inst. R. H. 257. tab. 133. Lin. Gen. Plant. 469. [This plant is called Ruta, of *ῥω* to preserve, because it is a plant very good to preserve health.] Rue.

The CHARACTERS are,

The flower has a short permanent empalement cut into five parts; it has four or five oval petals which spread open, and are narrow at their base, and eight or ten awl-shaped spreading stamina the length of the petals, crowned by short erect summits, with a gibbous germen having a cross furrow, marked with ten spots, supporting an erect awl-shaped style crowned by a single stigma. The germen afterward becomes a gibbous capsule with five lobes and five cells opening in five parts at the top, and filled with rough angular seeds.

This genus of plants is ranged in the first section of Linnæus's tenth class, which contains those plants whose flowers have ten stamina and one style.

The SPECIES are,

1. RUTA (*Hortensis*) foliis decompositis, floribus octandris, staminibus corollâ longioribus. Rue with decomposed leaves, and flowers having eight stamina which are longer than the petals. Ruta hortensis latifolia. C. B. P. 336. Broad-leaved Garden Rue.
2. RUTA (*Altera*) foliis decompositis, foliolis oblongo-ovatis, staminibus corollâ æquantibus. Rue with decomposed leaves, the small leaves oblong and oval, and stamina equalling the petals. Ruta hortensis altera. C. B. P. 336. Another Garden Rue.
3. RUTA (*Sylvestris*) foliis inferioribus decompositis, foliolis linearibus, summis quinquefidis trifidisque. Rue with decomposed linear leaves below, and the upper ones five or three-pointed. Ruta sylvestris minor. C. B. P. 336. Smaller wild Rue.
4. RUTA (*Chalepensis*) foliis decompositis, floribus decandris marginibus petalorum ciliatis. Rue with decomposed leaves, flowers having ten stamina, and the borders of the petals of the flower hairy. Ruta Chalepensis latifolia, florum petalis villis scatentibus. H. L. Broad-leaved Aleppo Rue with hairy petals to the flower.
5. RUTA (*Ciliatis*) foliis compositis, floribus decandris, petalis florum ciliatis. Rue with compounded leaves, flowers having ten stamina, and hairy petals to the flower. Ruta Chalepensis tenuifolia, florum petalis villis scatentibus. Mor. Hist. 2. 508. Narrow-leaved Aleppo Rue, with hairy petals to the flower.
6. RUTA (*Linifolia*) foliis simplicibus indivisis. Lin. Sp. Plant. 384. Rue with single undivided leaves. Ruta

R U T

sylvestris linifolia Hispanica. Bocc. Mus. 2. p. 82. Wild Spanish Rue with a Flax leaf.

7. RUTA (*Montana*) caule erecto corymbofo, foliis compositis, floribus decandris, staminibus corollâ longioribus. Rue with an erect corymbus stalk, compound leaves, and flowers having ten stamina which are longer than the petals. Ruta sylvestris montana. Clus. Hist. Wild Mountain Rue.

8. RUTA (*Patavina*) foliis terminatis sessilibus. Lin. Sp. 549. Rue with leaves without foot-stalks terminating the branches. Pseudo Ruta patavina trifolia, floribus luteis umbellatis. Michel. Gen. 22. tab. 19. Bastard Rue with trifoliate leaves, and yellow flowers in umbels. The first sort is the common Rue, which has been long cultivated in the gardens, and is that which is directed to be used in medicine, but of late years the second sort has so generally prevailed, as almost to supplant the first in the gardens about London; that being hardier than the first, is not so liable to be killed by severe frost.

The first rises with a shrubby stalk to the height of five or six feet, sending out branches on every side, garnished with decomposed leaves, whose small leaves (or lobes) are wedge-shaped; they are of a gray colour, and have a strong odour. The flowers are produced at the end of the branches, in bunches almost in form of umbels; they are composed of four yellow concave petals, which are cut on their edges, and eight yellow stamina which are longer than the petals, terminated by roundish summits. The germen becomes a roundish capsule, with four lobes punched full of holes, containing rough black seeds. It flowers in June, and the seeds ripen in autumn.

The second sort hath a shrubby stalk which rises three or four feet high, sending out many branches garnished with decomposed leaves, which are narrower than those of the former sort; they are of a bluish gray colour, and have a strong odour. The flowers grow in longer and looser bunches than the former; they have four short, concave, yellow petals, and eight short stamina of equal length with the petals. The seed-vessel is like that of the former, but smaller. This sort is more commonly to be found in gardens than the first.

The third sort grows naturally in Spain. The lower leaves of this are compounded of several parts, which are joined to the midrib in the same manner as other branching winged leaves, and are garnished with small linear leaves, standing without order. The stalks rise from two to three feet high, branching out from the bottom; these are garnished with leaves which are divided into five parts, and those at the top into three, which are as small and narrow as those at the bottom; they are of a gray colour, but are not so stinking as those of the other. The flowers grow at the end of the branches in loose spikes, which are generally reflexed; the petals of the flower are yellow, and appear in June; these are succeeded by small seed-vessels filled with angular black seeds. It flowers in June, and the seeds ripen in autumn.

The seeds of the fourth sort came from Aleppo, and it has also been brought from the Cape of Good Hope; this hath strong shrubby stalks which rise about three feet high, dividing into many branches, which are garnished with decomposed leaves larger than those of the common sort, and have a stronger odour. The flowers are disposed almost in form of an umbel at the end of the branches; they have five concave yellow petals, whose borders are set with fine hairs, and ten stamina which are of equal length with the petals. This sort flowers in June, and the seeds ripen in autumn. The seed-vessels of this are much larger than those of the common sort.

The fifth sort grows naturally at Aleppo; this hath shrubby stalks, which are smaller, and do not rise so high as those of the former sort. The leaves are much narrower and grayer than those, but have the same strong odour; the flowers are smaller, and have five petals, which are pretty close set with small hairs;

R U T

hairs; they have ten thick stamina, five of which are alternately longer than the petals; the seed-vessels are like those of the first sort.

The sixth sort grows naturally in Spain; this rises with several single stalks from the root near a foot and a half high, which are garnished with single leaves about three quarters of an inch long, and one eighth of an inch broad; they are of a yellowish green colour, and are placed alternately on the stalks, to which they sit pretty close; at the base of these come out one or two very small leaves, of the same shape and colour. The flowers grow in small clusters at the end of the stalks; they have each five oblong yellow petals, and ten stamina of equal length with them, terminated by awl-shaped summits. This flowers in June, and the seeds ripen in autumn; the plants are generally biennial in England.

The seventh sort rises with an erect stalk about two feet high, garnished with compound leaves, whose smaller leaves are narrow and obtuse, of a grayish colour, but have not so strong an odour as the former. The upper part of the stalk divides in form of a corymbus, sustaining upon naked foot-stalks small bunches of yellow flowers, which have five concave petals, and ten stamina which are much longer than the petals, terminated by roundish summits.

The eighth sort grows near Padua; this seems to be a plant of short duration; the stalk rises singly from the root, is about a foot high, herbaceous, and garnished with narrow trifoliate leaves placed alternately on the stalk, to which it closely adheres; the stalk branches at the top in form of an umbel, sustaining many yellow flowers, composed of five plain petals, having no hairs on their borders. It is propagated by seeds, which if sown in the autumn, soon after it is ripe, the plants will come up the following spring; but when the seeds are sown in the spring, the plants seldom rise the same year. If these grow upon poor ground, or in rubbish and in a warm situation, they will live in the open air without covering, but in rich ground they are frequently killed in winter.

All these plants may be propagated either by sowing of their seeds, or by planting slips or cuttings; both of which may be done in the spring. The manner of propagating them from cuttings being the same as for Lavender, Stæchas, and other hardy aromatic plants, need not be here repeated; and if they are propagated by seeds, there needs no farther care but to dig a bed of fresh earth in the spring, making it level; then to sow the seed thereon, and rake the ground smooth; after which, you must observe to keep the bed clear from weeds until the plants are come up about two inches high, when they should be transplanted out into fresh beds, where they may remain for use. All these plants must have a dry soil, otherwise they are very subject to be destroyed in winter. The two Aleppo Rues, and the wild Rues are tenderer than the common sort, so require shelter in winter; but the Aleppo Rues will endure our ordinary winters very well in the open air, especially if they are planted on a dry soil.

The sixth and seventh sorts are tenderer than either of the other, and are of shorter duration. The seeds of the seventh sort were sent me from Gibraltar Hill, where the plant grows naturally; this doth not ripen its seeds here, unless the summers are warm; and in hard winters the plants are generally killed, unless they are removed into shelter.

The sixth sort will live through the winter in the open air, provided it is planted in a poor dry soil, and the second year it will perfect seeds; but as it is of a short duration, young plants should be annually raised to succeed the others.

All the sorts of Rue will live much longer, and are less liable to be injured by frost in winter, when they grow in a poor, dry, rubbishy soil, than in good ground; for in rich moist land the plants grow very vigorously in summer, and are so replete with moisture, that a small frost will kill their tender shoots; where-

R U Y

as in poor dry ground, or when they grow upon old walls; their growth will not be great, but their shoots will be hard and compact, so are more able to resist the cold.

The first sort was formerly used to plant for edgings on the sides of borders; it was then called Herb of Grace, but was by no means proper for this use, for the plants shoot so vigorously; that there is no keeping them within the bounds of an edging; besides, when they are kept closely sheered, they appear to be very ragged and stumpy, and their roots spread so far as to exhaust the goodness of the soil, so that the other plants would be deprived of their nourishment, which reasons have caused them to be wholly neglected for this purpose; so that at present they are chiefly cultivated for medicinal use, or to furnish the balconies for the citizens in the spring, especially that with a variegated leaf.

RU TA CANINA. See SCROPHULARIA.

RU TA MURARIA, Wall-rue, or white Maiden-hair.

This plant is found growing out of the joints of old walls in divers parts of England, where it is gathered for medicinal use; but as it cannot be cultivated in gardens, so as to grow to advantage, I shall not say any thing more of it in this place.

RU YSCHIANA. Boerh. Ind. alt. 1. p. 172. Dracocephalum. Lin. Gen. Plant. 648.

The CHARACTERS are,

The flower hath a permanent empalement of one leaf, which is tubulous, and is cut into five segments at the top, the upper one being broader and blunter than the other; it is of the lip kind, having one petal which has a tube longer than the empalement. The chaps are large and swelling; the upper lip is erect and arched; it is gently indented at the top; the lower lip is trifid; the two side segments are narrow, and stand erect; the middle is broad, reflexed, and indented at the point. It hath four stamina, two of which are long, and situated under the upper lip; the other two are shorter, and situated just below them; they are terminated by oblong summits fastened in the middle: it has four germen situated at the bottom of the empalement, supporting a slender style the length of the stamina, crowned by a bifid reflexed stigma. The germen afterward become four oblong seeds which ripen in the empalement.

This genus of plants is joined to the Dracocephalum by Dr. Linnæus, which is ranged in the first section of his fourteenth class, containing the plants whose flowers have two long and two shorter stamina, and are succeeded by naked seeds ripening in the empalement.

The SPECIES are,

1. RUYSCHIANA (*Spicata*) floribus spicatis, foliis bracteisque linearibus glabris indivisis. *Ruyschiana with spiked flowers, linear leaves, and bractæ which are smooth and undivided.* Ruyschiana flore cæruleo magno. Boerh. Ind. alt. 1. p. 172. *Ruyschiana with a large blue flower.*
2. RUYSCHIANA (*Laciniata*) floribus spicatis, foliis linearibus trifidis hirsutis. *Ruyschiana with spiked flowers, and hairy, linear, three-pointed leaves.* Ruyschiana hirsuta, foliis laciniatis. Amman. Ruth. 50. *Hairy Ruyschiana with jagged leaves.*
3. RUYSCHIANA (*Verticillata*) floribus axillaribus, foliis lanceolatis dentatis glabris. *Ruyschiana with flowers growing at the wings of the stalks, and smooth, indented, spear-shaped leaves.* Dracocephalon foliis ex lanceolato-linearibus rariùs dentatis spinulosis, floribus gemellis. Gmel. *Dragon's-head with linear spear-shaped leaves which are rarely indented, and somewhat prickly, and flowers growing by pairs.*

The first sort grows naturally in Austria and Hungary; this hath a perennial root, and an annual stalk, which is four-cornered, and rises about two feet high, garnished with two smooth linear leaves at each joint, about one inch long, and one-eighth of an inch broad, with a deep furrow along the middle; and at each joint, at the other sides of the stalk,

R U Y

stalk, come out two or three very narrow small leaves of the same shape. The flowers are produced in whorled spikes at the top of the stalks, having small narrow leaves under each whorl. The flowers have tubulous empalements of one leaf, which are cut into five segments at the top, four of which are narrow, and end in acute points; the other, which is on the upper side of the flower is broader, and is rounded at the point. The tube of the flower is longer than the empalement, and is swelling and large at the chaps; the upper lip is broad, erect, and arched over the tube; the lower lip is shorter, and has two short side segments which are erect, but the middle segment is broad, rounded, and indented at the point, and is reflexed back to the tube. It has four stamina which lie close under the upper lip, and are arched in the same manner; two of these are as long as the style, which stands in the same position; the other two are shorter, and are situated just below the other; they are terminated by oblong summits, which are fastened in the middle to the stamina. The style is crowned by a bifid, reflexed, narrow stigma; the flowers appear in June, and are of a fine blue colour; these are each succeeded by four oblong seeds, which ripen in the empalement. The second sort grows naturally in Siberia; this was sent me by the late Dr. Amnian, who was professor of botany at Petersburg; it hath a perennial root. The stalks are four-cornered, hairy, and rise a foot and a half high, sending out several side branches, which are garnished with hairy linear leaves, cut into three parts; the flowers grow in short whorled spikes at the end of the stalk, having some very narrow leaves under each whorl; the tube of the flower is longer, and more equal in size than that of the former, and the middle segment of the lower lip is not so much reflexed. In other respects, the flowers are the same as those of the former.

The third sort grows naturally in Tartary; this hath a perennial root, and annual stalks which do not grow erect like the first, but spread nearer to an horizontal position; they divide into several branches, which have two large leaves opposite at each joint, and four smaller, two on each side between the larger; they are smooth, have sharp indentures on their edges, and stand erect. The flowers come out from the side of the stalks at the base of the leaves, two or three standing together on each side the stalk; their empalements are purple, and are cut into five acute segments at the top, the upper lip having three broad, and the lower two narrower. The upper lip of the flower is broad, indented at the point, and erect; the lower is trifid, but the middle segment is not so much reflexed as that of the first sort, and the flowers are of a paler blue than those. It flowers in June, and the seeds ripen in autumn.

R U Y

This name was given to this genus of plants by the learned Dr. Boerhaave, professor of botany at Leyden, in honour of Dr. Ruysch, who was professor of anatomy and botany at Amsterdam.

The plants are propagated by seed, which should be sown the latter end of March, in a bed of fresh light earth in an open exposure, and in about five or six weeks after the plants will appear, when they should be carefully cleared from weeds; and if the season should prove dry, they must be refreshed now and then with water, which will greatly promote their growth. When the plants are about two inches high, they should be carefully transplanted into a bed or border of fresh, light, undunged earth, observing to shade them from the sun until they have taken root, as also to refresh them from the sun until they are well established in this bed; after which time they will require no farther care, but to keep them constantly clear from weeds till Michaelmas, when they are to be removed into the places where they are designed to remain for good.

When the plants are first transplanted from the seed-bed into the nursery-bed, they should be planted about six inches asunder every way, which will be sufficient room for them the first season; and this will admit of the hoe to come between the plants to destroy the weeds, which is by much a better method than pulling out the weeds by hand, and is much sooner performed. For as the hoe stirs the ground between the plants, it not only cuts down the weeds which were up and visible, but also destroys all those whose seeds were sprouted, and would have soon after appeared; so that one hoeing, if well performed, and in dry weather, will more effectually destroy the weeds, than two hand-weedings would do, were they performed ever so carefully; besides, the stirring the ground is of great service to the plants.

At Michaelmas, when the plants are transplanted for good, they should be carefully taken up with balls of earth to their roots; and they must be planted in the middle of the borders in the pleasure-garden, in fresh light earth, intermixing them with other hardy plants of the same growth, where they will make a pretty appearance when they are in flower, and will continue three or four years; and in some poor stony soils I have known the roots live six or seven years, but these did not produce so large spikes of flowers, as those which were younger and more vigorous plants. Therefore, as these plants do not continue many years, it will be proper to raise a supply of young plants to succeed them, for the old plants will produce seeds plentifully, which are ripe the latter end of August or the beginning of September, when they should be gathered in dry weather, and kept in a warm dry room till the time for sowing them.

S A C

SABINA. See JUNIPERUS.
SACCHARUM. Lin. Gen. Plant. 68.
Arundo. C. B. P. 18. The Sugar Cane.

The CHARACTERS are,

It hath no empalement, but a woolly down longer than the flower incloses it. The flower is bivalve; the valves are oblong, acute-pointed, concave and chaffy. It has three hair-like stamina the length of the valves, terminated by

S A C

oblong summits, and an awl-shaped germen supporting two rough styles crowned by single stigmas. The germen afterward becomes an oblong acute-pointed seed, invested by the valves.

This genus of plants is ranged in the second section of Linnæus's third class, which includes the plants whose flowers have three stamina and two styles.

We

We have but one SPECIES of this genus at present, viz.

SACCHARUM (*Officinarum*) floribus paniculatis. Hort. Cliff. 26. *Sugar Cane with flowers growing in panicles.* Arundo saccharifera. C. B. P. 18. *The Sugar Cane.*

This plant grows naturally in both Indies, and is there cultivated also for its juice, which, when boiled, affords that sweet salt which is called Sugar.

The Canes were formerly cultivated in the south of France for the same purpose, but it was in small quantities only, for in sharp winters they were killed, unless they were covered, so that they had only the summer for their growth, which was too short time for their getting sufficient strength to produce Sugar enough to answer the expence, so the planting of these Canes there has been long discontinued; they were also planted in several parts of Spain before they were introduced to France, and are at present cultivated in plenty in Andalusia, from whence great quantities of Sugar are annually sent to Madrid, but there are few now planted in the other parts of Spain.

The root of this plant is jointed like those of the other sorts of Cane or Reeds, from which arise four, five, or more shoots in number, proportionable to the age or strength of the root. These rise eight or ten feet high, according to the goodness of the ground in which they grow; for in some moist rich soils there have been Canes measured, which were near twenty feet long; but these were not near so good as those of middling growth, as they abounded with juice, which had but a small quantity of the essential salt in it, so that the expence of fuel and trouble of boiling, was more than the Sugar would defray. The Canes are jointed, and these joints are more or less distant from each other, in proportion to the soil. The leaves are placed at each joint, and the base or lower part of the leaf embraces the stalk or Cane to the next joint above its insertion, before it expands; these are three or four feet long from the joint where they unfold to their point, according to the vigour of the plant; they have a deep whitish furrow, or hollowed midrib, which is broad, and prominent on the under side; the edges of the leaves are thin, and armed with small sharp teeth, which are scarce to be discerned by the naked eye, but will cut the skin of a tender hand if it be drawn along it. The flowers are produced in panicles at the top of the stalks; these are from two to three feet long, and are composed of many spikes, which are nine or ten inches long, and are again subdivided into smaller spikes; these have long down which inclose the flowers, so as to hide them from sight; afterward the germen becomes an oblong-pointed seed, which ripens in the valves of the flower.

This plant is preserved by way of curiosity in several gardens in England, but being too tender to thrive here, unless it is preserved in a warm stove, so it cannot be brought to any great perfection. I have seen some of the plants growing which were seven or eight feet high, and at the bottom as large as a common walking Cane, but they have not produced their panicles of flowers here.

It is here propagated by slips taken from the sides of the older plants; those which grow near the root and have fibres to them, will most certainly grow; so that when the shoots are produced at some distance from the ground, the earth should be raised about them, that they may put out fibres before they are separated from the mother plant. These slips should be planted in pots filled with rich kitchen-garden earth, and plunged into a moderate hot-bed of tanners bark, being careful to shade them from the sun until they have taken new root, after which they must be treated in the same way as other tender plants from the same countries. They must be constantly kept plunged in the tan-bed in the stove; and as their roots increase in size, so the plants should from time to time be shifted into larger pots; but this must be done with caution, for if they are over-potted they will not thrive: they

will require to have water frequently in warm weather; but it must not be given them in too great plenty, especially in cold weather. As the leaves of the plants decay, they should be cleared from about the stalks; for if these are left to dry upon them, it will greatly retard their growth. The stove in which this plant is placed, should be kept in winter to the same temperature of heat as for the Pine-apple, and in hot weather there should be plenty of free air admitted to the plants, otherwise they will not thrive.

I shall here subjoin some account of the method of propagating and cultivating the Sugar Cane in America, with some observations and experiments which have been made by a few curious persons in the British Islands, and shall propose some farther trials to be there made, in the culture and management of this useful plant, which are founded upon the experience I have had in the culture of some plants which are similar in their growth with the Sugar Cane.

The land which is most proper for the growth of Sugar Canes, is such as hath a sufficient depth of soil, and is not too moist and strong, but rather light and easy to work; for although strong moist ground will produce much taller and bigger Canes than the other, yet the quantity of Sugar will be much less, not near so good, and will require a greater quantity of fuel, and a longer time to boil, before the Sugar can be made; which is also the case with all fresh land, where there has not been any Canes growing before; therefore many of the most expert planters burn their land when it is first cleared for planting of Canes, to abate its fertility; but if when land is first cleared of the wood, and the roots of bad weeds, it is sown with Indigo, which such fresh ground will produce much better than the old, or such as has been long cultivated, there may be two or three crops of this taken, which will prepare the land for the Sugar Canes, without being at the trouble of burning it; but the growing of Indigo has been so little practised in the British Islands of America for many years past, as to be esteemed unworthy the notice of a Sugar planter; whereas if they would sometimes change their crops to other species; they would soon find an advantage in the growth, not only of their Canes, but also of their other crops: however, the usual practice is to continue the Canes always upon the same land as long as it will produce them, without changing the species, or allowing the ground a fallow to rest and recover itself. By this method there are some plantations so much exhausted, as that the crop of Sugar will scarce defray the expence of culture. Another thing should always be observed in the planting of fresh land with Canes, which is to allow them more room than is generally done; for as the ground is strong, so there will a greater number of shoots come out from each plant, and not having room to spread at bottom, they will draw each other up to a great height, and be full of watery juice, the sun and external air being excluded from the Canes by the multiplicity of leaves, which are both absolutely necessary to ripen and prepare the salts during the growth of the Canes.

If the ground is proper for the Sugar Canes, and they are planted at a good distance from each other, and the land is carefully managed, the same plantation may be continued above twenty years without replanting, and produce good crops the whole time; whereas in the common method, they are generally replanted in six or seven years, and in some of the poor land they are continued but two or three.

The Canes are in those warm countries propagated by cuttings or joints, of proper lengths; these are from fifteen to twenty inches long, in proportion to the nearness of their joints or eyes. These cuttings are generally taken from the tops of the Canes, just below the leaves; but if they were chosen from the lower part of the Canes, where they are less succulent and better ripened, they would not produce so luxuriant shoots, and their juice would be less crude, and contain a greater quantity of salts, which will be obtained

tained by less boiling than those Canes in the close manner they are commonly planted: this is well known to the judicious to be the case, in most kinds of vegetables; and it is by thus carefully propagating all kinds of esculent plants, either in the choice of the best seeds or cuttings, that most of the kinds have been so greatly improved of late years.

The distance which the Canes are usually allowed in planting, is from three to four feet, row from row, and the hills are about two feet asunder in the rows; in each of these hills they plant from four to seven or eight cuttings, which is a very great fault, and is the cause of most of their blights so much complained of lately; for if all these grow, which is often the case, they rob each other of their nourishment; and if a dry season happens before they have acquired strength, they are very soon stunted in their growth, and are then attacked by insects, which spread and multiply so greatly, as to cover a whole plantation in a little time: when this happens, the Canes are seldom good after, so that it will be the better way to root them entirely up when they are so greatly injured, for they very rarely recover this disorder; for although the insects are not the cause of the disease, yet they confirm it, and cause it to spread.

Therefore, if instead of planting so many, there was but one good cutting planted in each hill, or to prevent miscarriage, two at most; and if both succeeded, the weakest were drawn out soon after they had taken root, it will be found of great service to prevent these blights; and although the number of Canes will not be near so great from the same space of ground, yet the quantity of Sugar will be full as much, and will require little more than a fourth part of fuel to boil it.

I have been assured by two of the most sensible and judicious planters of Sugar in America, that they have made some experiments of the horse-hoeing culture for their Canes, which answered much beyond their expectations; one of those gentlemen told me, he planted one acre in the middle of a large piece of Canes, in rows at five feet asunder, and the hills were two feet and a half distant, and but one cutting to each hill. The ground between the rows was from time to time stirred with the horse plough, to destroy the weeds and earth the plants; with this culture the Canes were double the size of those in the same piece, which were cultivated in the usual way; and when the Canes were cut, those which had been thus planted and managed were ground and boiled separately; the produce of Sugar was full as great as the best acre in the same piece, and the expence of boiling was little more than a sixth part of the other, and he sold the Sugar for six shillings per hundred weight more than he could get for the other.

The time for planting the Canes is always in the rainy seasons, and the sooner they are planted after the rains have begun to fall, the more time they will have to get strength before the dry weather sets in; for when they have put out good roots, and are well established in the ground, they will not be so liable to suffer by the drought, as those which have but newly taken root.

The season being come for planting, the ground should be marked out by a line, that the rows of Canes may be strait, and at equal distances; but first it will be proper to divide the piece into lands of sixty or seventy feet broad, leaving intervals between each of about fifteen feet; these will be found of great use when the Canes are cut, for roads in which the carriages may pass to carry off the Canes to the mill; for where there is not such provision made, the carriages are obliged to pass over the heads of the Canes to their no small prejudice: besides, by these intervals, the sun and air will have freer passage between the Canes, whereby they will be better ripened, and their juice will be fuller of salts; therefore when the Canes are ground, they will not require so much fuel to boil their juice. The middle of these intervals may be planted with Yams, Potatoes, or other escu-

lent plants, which may be taken off before the Canes are cut, that the passages may be clear for the carriages; but a path should be left on the sides of each land, for the more convenient riding or walking of the overseer of the plantation, to view and observe how the labour is performed.

The common method now practised in planting of the Canes is, to make a trench with a hoe, which is performed by hand; into this one negro drops the number of cuttings intended for planting, at the distance the hills are designed; these are by other negroes placed in their proper position, then the earth is drawn about the hills with a hoe, all this is performed by hand; but if the right use of ploughs was well known in those countries, the work might be much better performed, and for less than half the expence; therefore instead of making a trench with a hoe, a deep furrow is made with a plough, and the cuttings properly laid therein, the ground will be deeper stirred, and there will be more depth for placing the Canes.

If the ground is to be afterward kept clean with the horse hoe, the rows of Canes should be planted five feet asunder, that there may be room for the horse and plough to pass between them; and the distance of the hills from each other should be two feet and a half, and but one Cane should be permitted to remain in each hill. After the Canes are planted and have made some shoots, the sooner the horse plough is used the better will the Canes thrive, and the ground will be easier kept clean from weeds; for if these are torn up when they are young, they will presently die; whereas when they are suffered to grow large before they are disturbed, they are with great difficulty destroyed.

As the growth of the Canes is promoted according to the cleanness of the ground, so there cannot be too much care taken to keep the Canes perfectly clear of weeds; and the beginning of this work soon will render it less troublesome, and it may be performed at a less expence, than when it is neglected for some time. When this is performed with a plough, the earth in the interval should be thrown up to the rows of Canes, first on one side of the row, being careful not to disturb the roots of the Canes, as also not to bury their new shoots; and in the second operation, the earth should be turned over to the other side of the rows, with the same care as before. By this turning and stirring of the land, it will be rendered looser, and the earthing of the plants will greatly strengthen them; so that from each hill there will be as many shoots produced as can be well nourished, and the sun and air will have free ingress among the rows, which will be of the greatest service to the Canes.

When the Canes are from seven to ten feet high, and of a proportionable size, the skin smooth, dry, and brittle, if they are heavy, their pith gray, or inclinable to brown, the juice sweet and glutinous, they are esteemed in perfection.

The time for cutting of the Canes is usually after they have grown six months; but there should not be a fixed period for this, for in some seasons and in different soils, there will be more than a month's difference in their maturity; and those who have made the experiments of cutting their Canes before they were ripe, and letting others stand till after they were ripe, have found the Sugar made from the latter, was much finer than that of the former, though the quantity was not quite so great; however, it will always be best to let them stand till they are in perfection before they are cut, but not longer.

They have also found those Canes which are cut toward the end of the dry seasons, before the rains begin to fall, have produced better Sugar than those which are cut in the rainy seasons, when they are more replete with watery juice; and there has been much less expence of fuel to boil it, which is a material article in large plantations; therefore the better the Canes are nourished in their growth, and the more

S A G

air and sun is admitted to pass between the rows, the less expence it will be in the boiling and preparing of the Sugar.

In the boiling of Sugar, they use a mixture of wood ashes and lime, which is called temper, without which the Sugar will not granulate. The quantity of this mixture is proportioned to the quality of the ground on which the Canes grew.

SAFFRON. See CROCUS.

SAGE. See SALVIA.

SAGITTARIA. Lin. Gen. Plant. 946. Sagitta. Dillen. Gen. 4. Ranunculus. Tourn. Inst. R. H. 287. Arrow-head.

The CHARACTERS are,

It hath male and female flowers on the same plant; the male flowers have a permanent empalement of three oval concave leaves; they have three roundish petals which spread open, and are larger than the empalement, and many awl-shaped stamina collected in a head, terminated by erect summits. The female flowers are situated below the male; these have a three-leaved empalement, and three petals as the male, but no stamina; they have many compressed germen collected in a head, sitting upon very short styles, and have permanent acute stigmas. The germen afterward become oblong compressed seeds having longitudinal borders, and are collected in globular heads.

This genus of plants is ranged in the eighth section of Linnæus's twenty-first class, which includes those plants which have male and female flowers on the same plant, whose male flowers have many stamina.

The SPECIES are,

1. SAGITTARIA (*Sagittifolia*) foliis omnibus sagittatis acutis petiolis longissimis. Arrow-head with all the leaves arrow-pointed, and long foot-stalks. Sagitta aquatica major. C. B. P. The greater Arrow-head.
2. SAGITTARIA (*Minor*) foliis sagittatis spatulisque, petiolis longioribus. Arrow-head with arrow-pointed and spatule-shaped leaves, having longer foot-stalks. Sagitta aquatica foliis variis. Lœff. Pruss. 234. Water Arrow-head with variable leaves.

The first sort grows naturally in standing waters in most parts of England; the root is composed of many strong fibres, which strike deep into the mud; the foot-stalks of the leaves are in length proportionable to the depth of the water in which they grow, so they are sometimes almost a yard long; they are round, thick, and fungous; the leaves which float upon the water are shaped like the point of an arrow, the two ears at their base spreading wide asunder, and are very sharp-pointed. The flowers are produced upon long stalks which rise above the leaves, and stand in whorls round them at the joints; they have each three broad white petals which spread open, and in the middle is a cluster of stamina with purple summits. It flowers in July. The flowers are succeeded by rough heads, containing many small seeds.

The second sort grows plentifully in standing waters near Paris, but has not been found wild in England. This never grows so large as the former; the leaves vary greatly, some of them are oblong, round-pointed, and shaped like a spatula; others are arrow-pointed, but these have their points less acute than those of the former, and the flowers are smaller, in which it differs from the former; and as all the plants where this grows retain their difference, so it may be supposed a different species.

There is also a third sort mentioned by Dr. Plukenet, under the title of Sagitta aquatica omnium minima, or the least Arrow-head. This grows plentifully on the borders of the Thames about Lambeth, and also at Chelsea; the foot-stalks of the leaves of this are very short, the leaves are much less, and the stalks which support the flowers are also very short; but these differences may be occasioned by the situation of their growth, for it is always found growing in the mud, which the water ebbs from every tide, so it is only covered in high water, which may stint the growth of the plants, and give them this appearance.

S A L

SALICARIA. See LYTHRUM.

SALICORNIA. Tourn. Cor. App. 51. tab. 485. Lin. Gen. Plant. 10. Jointed Glasswort, or Saltwort.

The CHARACTERS are,

The flower hath a rugged, swelling, four-cornered empalement, which is permanent. It has no petal, and but one stamina the length of the empalement, crowned by an oblong twin summit, and an oblong oval germen supporting a single style, crowned by a bifid stigma. The germen afterward becomes a single seed, inclosed in the swelling empalement.

This genus of plants Dr. Linnæus places in the first section of his first class, which contains those plants whose flowers have but one stamina and one style.

The SPECIES are,

1. SALICORNIA (*Fruticosa*) articulis apice crassioribus obtusis. Lin. Mat. Med. 8. Jointed Glasswort with thick obtuse points. Kali geniculatum. Ger. Emac. 535. Common jointed Glasswort.
2. SALICORNIA (*Perenne*) articulis apice acutioribus, caule fruticoso ramoso. Glasswort with acute points to the joints, and a shrubby branching stalk. Kali geniculatum perenne fruticosius procumbens. Raii Syn. Ed. 2. p. 67. Trailing, shrubby, perennial, jointed Glasswort.

The first sort grows plentifully in most of the salt-marshes which are overflowed by the tides, in many parts of England. This is a trailing plant, with thick, succulent, jointed stalks, which trail upon the ground, and divide into several branches. The flowers are produced at the ends of the joints toward the extremity of the branches, which are small, and scarce discernible by the naked eye. It flowers the latter end of July, and the seeds ripen in autumn.

The second sort grows naturally in Sheepey Island; this hath a shrubby branching stalk about six inches long; the points of the articulations are acute, the stalks branch from the bottom, and form a kind of pyramid; they are perennial, and produce their flowers in the same manner as the former.

The inhabitants near the sea-coast where these plants grow, cut them up toward the latter end of summer, when they are fully grown; and after having dried them in the sun, they burn them for their ashes, which are used in making of glass and soap. These herbs are, by the country people, called Kelp, and are promiscuously gathered for use.

From the ashes of these plants is extracted the salt, called sal kali, or alkali, which is much used by the chemists.

The manner of gathering and burning of these herbs is mentioned under the article of SALSOLA, so I shall not repeat it in this place.

In some parts of England these herbs are gathered and pickled for Samphire, though that is a very different plant from either of these.

SALIX. Tourn. Inst. R. H. 590. tab. 364. Lin. Gen. Plant. 976. [takes its name from salio, to leap or dance, because of its quick growth.] The Sallow, or Willow-tree; in French, Saule.

The CHARACTERS are,

It hath male and female flowers upon separate plants; the male flowers are disposed in one common, oblong, imbricated katkin. The scales have each one oblong spreading flower, which has no petal, but a cylindrical nectarious gland in the center. It has two slender erect stamina, terminated by twin summits having four cells. The female flowers are disposed in katkins as the male; these have neither petals or stamina, but an oval narrowed germen, scarce distinguishable from the style, crowned by two bifid erect stigmas. The germen afterward becomes an oval awl-shaped capsule with one cell, opening with two valves, containing many small oval seeds, crowned with hairy down.

This genus of plants is ranged in the second section of Linnæus's twenty-second class, which contains those plants which have male and female flowers on separate plants, whose male flowers have two stamina. There are several species of this genus which grow naturally in the northern parts of Europe, of little or

S A L

no use, being low creeping shrubs, many of them seldom rising a foot high, so are never cultivated, therefore I shall pass them over, and only enumerate those which are planted for use.

The SPECIES are,

1. SALIX (*Alba*) foliis lanceolatis acuminatis ferratis utrinque pubescentibus, ferraturis infimis glandulosis. Hort. Cliff. 473. Willow with spear-shaped, acute-pointed, sawed leaves, which are downy on both sides, and glands below the saws. Salix vulgaris alba, arborescens. C. B. P. 453. Common white Tree Willow.
2. SALIX (*Triandra*) foliis ferratis glabris, floribus triandris. Lin. Sp. Plant. 1015. Willow with smooth sawed leaves, and flowers having three stamina. Salix folio auriculato splendente flexilis. Raii Hist. 1420. Willow with lucid eared leaves and flexible branches.
3. SALIX (*Pentandra*) foliis ferratis glabris, flosculis pentandris. Hort. Cliff. 454. Willow with smooth sawed leaves, and flowers having five stamina. Salix folio laureo seu lato glabro odorato. Raii Hist. 1420. Willow with a Bay leaf, or broad-leaved, smooth, sweet Willow.
4. SALIX (*Vitellina*) foliis ferratis ovatis acutis glabris, ferraturis cartilagineis, petiolis callosis punctatis. Hort. Upsal. 295. Willow with smooth, oval, acute, sawed leaves, having cartilaginous indentures, and foot-stalks with callous punctures. Salix fativa lutea, folio crenato. C. B. P. 473. Yellow cultivated Willow with a crenated leaf.
5. SALIX (*Amygdalina*) foliis ferratis glabris lanceolatis petiolatis, stipulis trapeziformibus. Flor. Leyd. Prod. 83. Willow with smooth, spear-shaped, sawed leaves having foot-stalks, and trapezium-shaped stipules. Salix folio amygdalino, utrinque virente aurito. C. B. P. 43. Almond-leaved Willow with leaves which are eared, and green on both sides.
6. SALIX (*Fragilis*) foliis ferratis glabris ovato-lanceolatis, petiolis dentato-glandulosis. Flor. Lapp. 349. Willow with oval, spear-shaped, smooth, sawed leaves, and indented glandules to the foot-stalk. Salix folio longo latoque splendente fragilis. Raii Syn. 3. p. 448. The Crack Willow.
7. SALIX (*Purpurea*) foliis ferratis glabris lanceolatis, inferioribus oppositis. H. Scan. 252. Willow with smooth, spear-shaped, sawed leaves, the lower of which grow opposite. Salix folio longo subluteo non auriculato, viminibus rubris. Raii Syn. The long-leaved red Willow.
8. SALIX (*Viminalis*) foliis subintegerrimis lanceolato-linearibus longissimis acutis subtus sericeis, ramis virgatis. Flor. Suec. 813. Willow with the longest, linear, spear-shaped, acute leaves, which are almost entire, and silky on their under side, and rod-like branches. Salix foliis angustis & longissimis crispis, subtus albicantibus. J. B. I. p. 212. Willow with the longest, narrow, curled leaves, which are white on their under side.
9. SALIX (*Auriculata*) foliis ferratis glabris lanceolatis, omnibus alternis. Willow with smooth, spear-shaped, sawed leaves, all growing alternate. Salix folio amygdalino utrinque aurito, corticem abjiciens. Raii Syn. 3. p. 448. Almond-leaved Willow which is eared on both sides, and casts its bark.
10. SALIX (*Rubra*) foliis integris, glabris lineari-lanceolatis acutis. Hudf. Flor. Angl. 364. Willow with linear, spear-shaped, smooth leaves. Salix minimè fragilis, foliis longissimis, utrinque viridibus non ferratis. D. Sherard. Raii Syn. 2. p. 293. The least brittle Willow, with very long leaves which are green on both sides, and not sawed.
11. SALIX (*Babylonica*) foliis ferratis glabris lineari-lanceolatis, ramis pendulis. Hort. Cliff. 454. Willow with smooth, sawed, linear, spear-shaped leaves, and hanging branches. Salix Orientalis, flagellis deorsum pulchre pendentibus. Tourn. Cor. 41. The Weeping Willow.
12. SALIX (*Helix*) foliis ferratis glabris lanceolato-linearibus, superioribus oppositis obliquis. Flor. Leyd. Prod. 83. Willow with linear, spear-shaped, smooth, sawed leaves, the upper of which are placed obliquely op-

S A L

posite. Salix humilior foliis angustis subcæruleis ex adverso binis. Raii Syn. 2. p. 297. The yellow Dwarf Willow.

13. SALIX (*Caprea*) foliis ovatis rugosis, subtus tomentosis undatis supernè denticulatis. Flor. Leyd. Prod. 83. Willow with oval rough leaves which are waved, woolly on their under side, and indented towards the top. Salix latifolia rotunda. C. B. P. 474. Broad round-leaved Willow, or Sallow.
14. SALIX (*Acuminata*) foliis oblongo-ovatis acuminatis rugosis subtus tomentosis. Willow with oblong, oval, acute-pointed, rough leaves, which are woolly on their under side. Salix folio ex rotunditate acuminato. C. B. P. 474. Willow with a rounded, acute-pointed leaf, or common Sallow.

The first sort is the common white Willow, which is frequently found growing on the sides of rivers and ditches in many parts of England. It grows to a large size, if the branches are not lopped off; the shoots are covered with a smooth, pale, green bark; the leaves are spear-shaped, between three and four inches long, and one broad in the middle, drawing to a point at each end; they are very white on their under side, and their upper side is covered with short, white, woolly hairs, though not so closely as the under; the katkins are short and pretty thick. The wood of this sort is very white, and polishes smooth.

The second sort grows to be a large tree, the young branches are covered with a grayish bark; the leaves are smooth, of a lucid green, ending in acute points; they are eared at their base, and sawed on their edges, and are green on both sides; the branches grow pretty erect and are flexible, so this is frequently planted in Osier-grounds for the basket-makers. The katkins of this are long, narrow, and the scales open, and are acute-pointed.

The third sort hath thick strong shoots, covered with a dark green bark; the leaves are broad, rounded at both ends; they are very smooth, sawed on their edges, and when rubbed have a grateful odour. It is sometimes called the Bay-leaved Willow, and at others the Sweet Willow; it grows quick, and is a tree of middling size; the branches are brittle, so are not proper for many purposes.

The fourth sort has slender tough shoots, which are of a yellow colour; the leaves are oval, acute-pointed, smooth, and sawed on their edges; the saws are cartilaginous, and the foot-stalks of the leaves have callous punctures. This is very pliable, so is much planted in the Osier-grounds for the basket-makers, but it never grows to a large size.

The fifth sort grows to a pretty large size; the shoots are erect, they are covered with a light green bark; the leaves are spear-shaped, about two inches and a half long, and three quarters of an inch broad in the middle, drawing to a point at both ends; they are of a lucid green on both sides, sawed on their edges, standing upon short foot-stalks; they have stipulæ in form of a trapezium, at the base of the foot-stalk. The twigs of this sort are flexible, and fit for the use of basket-makers.

The sixth sort grows to a middling size; the shoots of this are very brittle, so are unfit for the basket-makers, and are covered with a brownish bark; the leaves are near five inches long and one broad; they are of a lucid green on both sides, and are sawed on their edges; the katkins are long and slender, and the scales are pretty long, acute-pointed, and stand open. It is commonly called Crack Willow, from the branches being very brittle.

The seventh sort is a tree of middling size; the shoots are very pliable, and fit for the basket-makers, so is much planted in the Osier-grounds; they are of a reddish colour; the leaves are spear-shaped, smooth, and sawed on their edges; those on the lower part of the branches are placed opposite, but on the upper they are alternate, and are of a yellowish green.

The eighth sort makes very long shoots, but the tree seldom grows to a large size; the leaves are very long and entire, and are set close upon the branches; they are

are of a dark green on their upper side, but are very woolly and white on their under, ending in acute points, and stand upon very short foot-stalks: the young branches of this sort are woolly, and their buds are very turgid. This is pretty much planted in the Osier-grounds, for the use of basket-makers.

The ninth sort is a tree of middling growth; it casts its bark annually; the shoots are brittle, they have a yellowish bark; the leaves are spear-shaped, and sawed on their edges; they are eared on both sides at their base, and are all placed alternate, being of a light green on both sides. This sort is not very commonly cultivated, the twigs being too brittle.

The tenth sort hath very pliant branches, so is much planted in the Osier-grounds. The leaves of this are very long; they are spear-shaped and entire, and are green on both sides. It grows to a middling size, if planted in moist land.

The eleventh sort grows naturally in the Levant, but has been several years cultivated in the English gardens. This will grow to a middling size; the branches are long, slender, and hang down on every side, so form natural arches; the leaves are narrow, spear-shaped, smooth, and sawed on their edges. It is well known in the gardens, by the title of Weeping Willow.

The twelfth sort is a tree of lower growth; the branches of this are erect; the leaves are smooth, narrow, spear-shaped, and sawed on their edges; they are of a dark or bluish green, and toward the upper part of the branches are placed opposite. It is found by the side of ditches in many parts of England.

The thirteenth sort grows naturally upon dry land, and on high situations, but rarely is seen of a large size; the bark is of a gray dark colour, and smooth; the branches are brittle, so are unfit for basket-makers, but it is frequently cultivated in hedges, and for fuel in many parts of England: it is called Mountain Osier. The leaves are oval, rough, and woolly, and are indented toward the top; they are about an inch and a half long, and one inch broad, rounded at both ends, and have short foot-stalks. There is a variety of this in the gardens with variegated leaves.

The fourteenth sort is the common Sallow; this differs from the last, in having longer leaves which end in acute points; they are woolly on their under side, and sit close to the branches; they are not distinguished by the farmers, who cultivate them equally.

There are some other sorts of Willows which are planted in the Osier-grounds, and are distinguished by the basket-makers and dealers in them, under titles which they have applied to them, which are little known to others; these are annually cut down, and always kept low, but when they are not cut down, and have room to grow, will rise to a considerable height, and some of them will become large trees; so that they may be planted for the same purposes as the first sort, and will make a variety when intermixed with it, though they are commonly cultivated for their twigs, which produce good profit to the owner of the land.

All the sorts of Willows may be easily propagated by planting cuttings or sets, either in the spring or autumn, (but the spring is the surest season) which readily take root, and are of a quick growth. Those sorts which grow to be large trees, and are cultivated for their timber, are generally planted from sets, which are about seven or eight feet long; these are sharpened at their larger end, and thrust into the ground by the sides of ditches and banks, where the ground is moist; in which places they make a considerable progress, and are a great improvement to such estates, because their tops will be fit to lop every sixth or seventh year. This is the usual method now practised in most parts of England, where the trees are cultivated, as they are generally intended for present profit; but if they are designed for large trees, or are cultivated for their wood, they should be planted in a different manner; for those which are

planted from sets of seven or eight feet long always send out a number of branches toward the top, which spread, and form large heads fit for lopping, but their principal stem never advances in height; therefore, where regard is paid to that, they should be propagated by short young branches, which should be put almost their whole length in the ground, leaving only two, or at most but three buds out of the ground; and when these have made one year's shoot, they should be all cut off, except one of the strongest and best situated, which must be trained up to a stem, and treated in the same way as timber trees. If these are planted with such design, the rows should be eight feet asunder, and the sets four feet distance in the rows; by planting them so close, they will naturally draw each other upward, and, when they are grown so large, as to cover the ground and meet, they should be gradually thinned, so as at the last to leave the rows about twelve feet asunder, and the plants in the rows eight. If they are so treated, the trees will grow to a large size, and rise with upright stems to the height of forty feet or more.

When these cuttings are planted, it is usual to sharpen those ends to a point which are put into the ground, for the better thrusting of them in; but the best way is to cut them horizontally just below the bud or eye, and to make holes with an iron instrument in the ground where each cutting is to be planted, and when they are put in, the ground should be pressed close about the cuttings with the heel to settle it, and prevent the air from penetrating deep into the ground. The after care must be to keep them clear from weeds the two first seasons, by which time they will have acquired so much strength, as to over-power and keep down the weeds; they will also require some trimming in winter to take off any lateral shoots, which, if suffered to grow, would retard their upright progress.

There are great tracts of land in England fit for this purpose, which at present produce little to the owners, and might, by planting of these trees, turn to as good account as the best Corn land. The larger wood, if sound, is commonly sold for making wooden heels for shoes; as also to turners for many kinds of light ware.

The Sallows are commonly planted in cuttings made from strong shoots of the former year, about three feet long; these are commonly thrust down two feet deep into the ground, and are one foot above it. The cuttings should be placed about five feet row from row, and two feet asunder in the rows, observing always to plant the rows the sloping way of the ground (especially if the tides overflow the place;) because, if the rows are placed the contrary ways, all the filth and weeds will be detained by the sets, which will choak them up.

The best season for planting these cuttings in the Osier-grounds is in February, for if they are planted sooner, they are apt to peel, if it proves hard frost, which greatly injures them. These plants are always cut every year, and, if the soil be good, they will produce a great crop, so that the yearly produce of one acre has been often sold for fifteen pounds, but ten pounds is a common price, which is much better than Corn land; so that it is great pity these plants are not more cultivated, especially upon moist boggy soils, upon which few other things will thrive.

S A L SOLA. Lin. Gen. Plant. 275. Kali. Tourn. Inst. R. H. 247. tab. 128. Glasswort; in French, Soude.

The CHARACTERS are,

The empalement of the flower is permanent, and composed of five oval obtuse leaves; the flower has no petals, but hath five short stamina which are inserted in the divisions of the petals; it hath a globular germen, with a short two-pointed style, crowned by recurved stigmas. The germen afterward becomes a globular capsule with one cell, wrapped up in the empalement, inclosing one large seed.

This genus of plants is ranged in the second section of Linnæus's fifth class, which includes those plants whose flowers have five stamina and two styles.

The SPECIES are,

1. SALSOLA (*Kali*) herbacea decumbens, foliis subulatis spinosis, calycibus marginatis axillaribus. Lin. Sp. Plant. 222. *Herbaceous trailing Salsola with awl-shaped prickly leaves, and empalements proceeding from the sides of the stalks.* Kali spinosum foliis crassioribus & brevioribus. Tragum. Matth. 1035. *Prickly Glasswort with shorter and thicker leaves.*
2. SALSOLA (*Tragus*) herbacea erecta, foliis subulatis spinosis lævibus, calycibus ovatis. *Herbaceous Salsola with awl-shaped prickly leaves, and oval empalements.* Kali spinosum, foliis longioribus & angustioribus. Tourn. Inst. R. H. 247. *Prickly Glasswort with longer and narrower leaves.*
3. SALSOLA (*Soda*) herbacea, foliis inermibus. Guett. Stamp. 426. *Herbaceous Salsola with smooth leaves.* Kali majus cochleato semine. C. B. P. 287. *Greater Glasswort with a cochleated leaf.*
4. SALSOLA (*Vermiculata*) frutescens, foliis ovatis acutis carnosiss. Lin. Sp. Plant. 223. *Shrubby Salsola with oval, fleshy, acute-pointed leaves.* Kali fruticosum Hispanicum, tamarisci folio. Tourn. Inst. R. H. 247. *Shrubby Spanish Glasswort with a Tamarisk leaf.*
5. SALSOLA (*Rosacca*) herbacea, foliis subulatis mucronatis, calycibus explanatis. Lin. Sp. Plant. 222. *Herbaceous Salsola with pointed awl-shaped leaves, and spreading empalements.* Kali humile, alis purpureis florem rosaceum mentientibus. Buxb. Cent. 1. p. 9. *Dwarf Glasswort, having purple wings which resemble a Rose flower.*

The first sort grow naturally in the salt-marshes in divers parts of England; it is an annual plant, which rises about five or six inches high, sending out many side branches from the bottom, which spread on every side; these are garnished with short awl-shaped leaves which are fleshy, and terminate in acute spines. The flowers are produced from the sides of the branches, to which they sit close, and are encompassed by short prickly leaves; they are small, and of an herbaceous colour. The seeds are wrapped up in the empalement of the flower, and ripen in autumn, soon after which the plants decay.

The second sort grows naturally on the sandy shores of the south of France, Spain, and Italy; this is also an annual plant, which sends out many diffused stalks a foot and a half long, which are garnished with linear leaves an inch long, ending with sharp spines. The flowers come out from the side of the stalks in the same manner as those of the former; their empalements are blunt, and not so closely encompassed with leaves as those of the other.

The third sort rises with herbaceous stalks near three feet high, sending out hoary branches their whole length, which at bottom spread out wide, but toward the top they are short. The leaves on the principal stalk, and those on the lower part of the branches, are long, slender, and have no spines; those on the upper part of the stalk and branches are slender, short, and crooked. At the base of the leaves are produced the flowers, which are small and hardly perceptible; the empalement of the flower afterward encompasses the capsule, which contains one cochleated seed. This sort in warm countries produces its flowers in June, and the seeds ripen in August; but in this country the plants scarce ever flower, unless the summer is very warm. This plant is cultivated about Montpellier in salt-marshes, in order to make sal alkali.

The fourth sort grows naturally in Spain; this hath shrubby perennial stalks which rise three or four feet high, sending out many side branches, which are garnished with fleshy, oval, acute-pointed leaves, coming out in clusters from the side of the branches; they are hoary, and have no stiff prickles. The flowers are produced from between the leaves toward the ends of the branches; they are so small as scarce to be discerned, unless they are closely viewed. The seeds are like those of the other kinds.

The fifth sort grows naturally in Tartary; this is an

annual plant whose stalks are herbaceous, and seldom rise more than five or six inches high. The leaves are awl-shaped, ending in acute points; the flowers are small, and of a Rose colour, but soon fade; the seeds are like those of the other sorts.

All the sorts of Glasswort are sometimes promiscuously used for making the sal alkali, but it is the third sort which is esteemed best for this purpose. The manner of making it is as follows: having dug a trench near the sea, they lay laths across it, on which they lay the herb in heaps, and having made a fire below, the liquor which runs out of the herbs drops to the bottom, which at length thickening becomes sal alkali, which is partly of a black, and partly of an Ash colour, very sharp and corrosive, and of a saltish taste. This, when thoroughly hardened, becomes like a stone, and is there called soude or fode. It is transported from thence to other countries for making of glass.

SALT is a fossil body, fusible by fire, and congealable again, in the cold, into brittle glebes or crystals; soluble withal in water, so as to disappear therein; never malleable, and having something in it, which, to the organ of taste, affords a sensation of acrimony and sharpness.

Dr. Grew supposes, That the chief governing principle in the juices of plants is the saline or Salt, which saline principle is to be understood as a general term. The vegetable Salts seem to be four, viz. the nitrous, the acid, the alkaline, and the marine. The nitrous Salts seem by nature to be assigned chiefly to the growth of plants, and the other three Salts are exhibited by the several ways of resolving the principles of a plant.

Salt is accounted a good dressing for cold lands, because the nature of it is such, that the drier and hotter it is kept, the more it keeps its own body, and does not turn to water: but when it stands in a cold moist place, in a little time it dissolves to water, and, when turned to water, is fit for the nourishment and feeding of plants, especially annuals.

The reason why Salt, viz. Salt water, is accounted a feeder of plants, is, that it has been often observed that Salt falling on a board, &c. will be long drying; and, if it has been dried by heat, dews, or rain, will make it moist again, and then it steams forth, and that is it which nourishes all plants; but, if it be upon a hot and dry ground, late in the spring, and dry weather comes, it does not, nor can yield its steam or fume.

Pigeons dung is by many esteemed good for cold lands, because it is hotter and saltier than any other dung, it being natural to pigeons to eat Salt, for they fly to the sea side early on mornings to pick up the Salt, which the heat of the sun makes by drying up the Salt water, and leaves upon the sand.

The Rev. Dr. Hales, in his excellent Treatise of Vegetation, observes, that plants are of a less durable texture, as they abound with a greater proportion of Salt and water, which is not so strongly attracted as sulphur and air, so they are the less able to endure the cold; and, as plants are observed to have a greater proportion of Salt and water in them in the spring than in autumn, they are more easily injured by cold in the spring, than in a more advanced age, when their quantity of oil is increased, with their greater maturity.

Whence we find, that nature's chief business in bringing the parts of a vegetable, especially its fruit and seed, to a maturity, is to combine together, in a due proportion, the more active and noble principles of sulphur and air, that chiefly constitute oil, which in its most refined state is never found without some degree of earth and Salt in it.

Common Salt, if it could be obtained at a reasonable rate, would be an excellent dressing for most lands, but the exorbitant duty which is laid upon it, renders it too expensive to be used for this purpose, so that it is needless to mention its usefulness.

SALVIA.

SALVIA. Tourn. Inst. R. H. 180. tab. 83. Lin. Gen. Plant. 36. [so called from *salvus*, or *salus vitæ*, i. e. the health of life.] Sage; in French, *Sauge*.

The CHARACTERS are,

The empalement of the flower is tubulous, of one leaf, striated, and large at the mouth, where it is cut into four parts. The flower is of the lip kind, of one petal; the lower part is tubulous, the upper is large and compressed; the upper lip is concave, incurved, and indented at the point; the lower lip is broad and trifid, the middle segment being large, roundish, and indented. It has two short stamina which stand transverse to the lip, and are fixed in the middle to the tube, to whose tops are fixed glands, upon the upper side of which sit the summits; it has a four-pointed germen supporting a long slender style, situated between the stamina, crowned by a bifid stigma. The germen afterward becomes four roundish seeds which ripen in the empalement.

This genus of plants is ranged in the first section of Linnaeus's second class, which includes those plants whose flowers have two stamina and one style. To this genus he has added the *Horminum* and *Sclarea* of Tournefort, which, according to his system, may be joined together; but as there is a difference in the lips of the flowers, I have chosen to keep the three genera distinct, because they have always been known by their different titles both in the gardens and shops.

The SPECIES are,

1. **SALVIA** (*Officinalis*) foliis lanceolatis-ovatis integris crenulatis, floribus verticillato-spicatis. Sage with spear-shaped, oval, entire leaves, which are slightly crenated on their edges, and flowers growing in whorled spikes. *Salvia major*. C. B. P. The greater Sage.
2. **SALVIA** (*Tomentosa*) foliis infimis cordatis, summis oblongo-ovatis serratis tomentosis, floribus verticillato-spicatis. Sage with heart-shaped lower leaves, the upper are oblong, oval, sawed, and woolly, and flowers growing in whorled spikes. *Salvia latifolia* ferrata. C. B. P. 237. Broad-leaved sawed Sage.
3. **SALVIA** (*Auriculata*) foliis lanceolatis sæpius articulatis subtus tomentosis, floribus spicato-verticillatis, calycibus ventricosis. Sage with spear-shaped leaves which are frequently eared, and woolly on their under side, flowers growing in whorled spikes, and bellied empalements. *Salvia minor aurita* & non aurita. C. B. P. 237. Smaller Sage with leaves eared and eared, commonly called Sage of Virtue.
4. **SALVIA** (*Hispanica*) foliis lineari-lanceolatis integerrimis tomentosis, floribus spicatis calycibus brevissimis ventricosis acutis. Sage with linear, spear-shaped, woolly, entire leaves, spiked flowers, and the shortest bellied empalements ending in acute points. *Salvia Hispanica Lavendulæ folio*. Tourn. Inst. R. H. 181. Spanish Sage with a Lavender leaf.
5. **SALVIA** (*Fruticosa*) foliis infimis pinnatis, summis ternatis rugosis, floribus spicatis, caule fruticoso tomentosa. Sage with winged lower leaves, the upper ones trifoliate and rough, flowers growing in spikes, and a shrubby woolly stalk. *Salvia orientalis Absinthium redolens*, foliis pinnatis, flore carneo elatior. Sherard. Act. Phil. Lond. 383. Taller Eastern Sage with a Wormwood smell, winged leaves, and a flesh-coloured flower.
6. **SALVIA** (*Pomifera*) foliis lanceolato-ovatis integris crenulatis, floribus spicatis, calycibus obtusis. Hort. Cliff. 12. Sage with spear-shaped, oval, entire leaves which are slightly crenated, spiked flowers, and blunt empalements. *Salvia Cretica frutescens pomifera*, foliis longioribus incanis & crispis. Tourn. Cor. 10. Shrubby Apple-bearing Sage of Crete, with longer, hoary, and curled leaves.
7. **SALVIA** (*Pinnata*) foliis compositis pinnatis. Hort. Cliff. 13. Sage with compound winged leaves. *Salvia orientalis, latifolia, hirsutissima, viscosa, pinnata*, flore & calyce purpureis inodora. Boerh. Ind. alt. 1. p. 167. Eastern, broad-leaved, hairy, unsavoury Sage, with clammy winged leaves, and the flowers and empalements purple.
8. **SALVIA** (*Orientalis*) foliis infimis pinnatis, summis simplicibus crenatis, floribus verticillatis caulibus procumbentibus hirsutissimis. Sage with winged lower

leaves, the upper ones single and crenated; flowers growing in whorls, and the most hairy trailing stalks. *Salvia orientalis, latifolia, Absinthium redolens*, flore carneo magno. Boerh. Ind. alt. 1. p. 167. Eastern, broad-leaved, Wormwood Sage, with a large flesh-coloured flower.

9. **SALVIA** (*Dominica*) foliis cordatis obtusis crenatis subtomentosis, corollis calyce angustioribus. Lin. Sp. Plant. 25. Sage with heart-shaped, blunt, crenated leaves which are somewhat woolly, and the petals narrower than the empalement. *Velezia* Monier. The *Velezia* of Dr. Monier.

10. **SALVIA** (*Aurea*) foliis subrotundis integerrimis, basi truncatis dentatis. Hort. Cliff. 13. Sage with roundish entire leaves which are torn, and indented at their base. *Salvia Africana frutescens*, folio subrotundo glauco, flore magno aureo. Hort. Amst. 2. p. 183. Shrubby African Sage with a roundish gray leaf, and a large golden flower.

11. **SALVIA** (*Africana*) foliis subrotundis serratis, basi truncatis dentatis. Hort. Cliff. 13. Sage with roundish sawed leaves which are torn, and indented at their base. *Salvia Africana frutescens*, folio scorodoniæ, flore violaceo. Hort. Amst. 2. p. 18. Shrubby African Sage, with a Wood Sage leaf and a Violet flower.

12. **SALVIA** (*Integerrima*) foliis oblongo-ovatis integerrimis, calycibus patulis coloratis. Tab. 225. fig. 2. Sage with oblong, oval, entire leaves, and spreading coloured empalements.

The first sort is the common large Sage which is cultivated in gardens, of which there are the following varieties: 1. The common green Sage. 2. The Wormwood Sage. 3. The green Sage with a variegated leaf. 4. The red Sage. 5. The red Sage with a variegated leaf; these are accidental variations, and therefore are not enumerated as species. The common Sage grows naturally in the southern parts of Europe, but is here cultivated in gardens for use; but that variety with red or blackish leaves is the most common in the English gardens, and the Wormwood Sage is in greater plenty here than the common green-leaved Sage, which is but in few gardens. The common Sage is so well known as to require no description.

The second sort is generally titled balsamic Sage by the gardeners. The stalks of this do not grow so upright as those of the common Sage; they are very hairy, and divide into several branches, which are garnished with broad, heart-shaped, woolly leaves, standing upon long foot-stalks; they are sawed on their edges, and their upper surfaces are rough; the leaves, which are upon the flower-stalks, are oblong and oval, standing upon shorter foot-stalks, and are very slightly sawed on their edges; the flowers grow in whorled spikes toward the top of the branches; the whorls are pretty far distant, and but few flowers in each; they are of a pale blue, and about the size of those of the common sort. It flowers in June, and in good seasons the seeds ripen in autumn. This Sage is preferred to all the others for making tea.

The third sort is the common Sage of Virtue, which is also well known in the gardens and markets. The leaves of this are narrower than those of the common sort; they are hoary, and some of them are indented on their edges toward the base, which indentures have the appearance of ears. The spikes of flowers are longer than those of the two former sorts, and the whorls are generally naked, having no leaves between them. The flowers are smaller, and of a deeper blue than those of the common red Sage.

The fourth sort grows naturally in Spain. The leaves of this are very narrow and entire, standing in clusters on the side of the stalks; they are very hoary, and the branches are covered with a hoary down; the leaves on the upper part of the stalk are narrower than those of Rosemary; the flowers grow in closer spikes than either of the former, and are of a light blue colour.

The fifth sort grows naturally about Smyrna, from whence the late Dr. William Sherard sent the seeds, which succeeded in the Chelsea Garden. This rises with a shrubby stalk four or five feet high, and divides into

into several branches which grow erect. The leaves on the lower branches are winged, being composed of two or three pair of small lobes, terminated by one large one. Those which grow on the flowering branches are trifoliate, the two inner lobes being small, and the outer one is large, ending in a point; they have the flavour of Wormwood, and their upper surface is rough. The flowers grow in long spikes at the end of the branches; the whorls are pretty close to each other, and have no leaves between them; the flowers are large, and of a flesh colour. This flowers in July, but never produces good seeds in England.

The sixth sort grows naturally in Crete; this hath a shrubby stalk which rises four or five feet high, dividing into several branches, which are garnished with spear-shaped, oval, entire, woolly leaves, slightly crenated on their edges. The flowers grow in spikes at the end of the branches; they are of a pale blue colour, and have obtuse empalements. The branches of this Sage have often punctures made in them by insects, at which places grow large protuberances as big as Apples, in the same manner as the galls upon the Oak, and the rough balls on the Briar.

The seventh sort grows naturally in the Levant; this is an annual or biennial plant, with trailing stalks. The leaves on the lower part of the stalks are composed of two or three small pair of lobes, terminated by one large one; those farther up are trifoliate, the outer lobe being four times the size of the side ones. The flowers grow in whorls round the stalks; they are large, and of a deep blue colour, as are also their empalements. This flowers in July, and the seeds ripen in autumn, soon after which the plants generally decay.

The eighth sort grows naturally about Smyrna, where the late Dr. Sherard gathered the seeds; this is a perennial plant with trailing stalks, which grow near two feet long, garnished toward the bottom with leaves composed of two pair of small lobes terminated by a large one, but those toward the top are single and stand opposite. The flowers are produced in whorls round the stalks; they are large, and of a flesh colour, but are not succeeded by seeds here.

The ninth sort grows naturally at St. Domingo; this is an annual plant, which rises with an erect, four-cornered, branching stalk three or four feet high, garnished with large heart-shaped leaves of a bright green colour, which are obtusely crenated on their edges, having several veins on their lower side, which diverge from the midrib to the sides. Their foot-stalks are long and slender; the flowers are produced in close spikes at the end of the branches; they are of a fine blue colour, and their tubes are narrower than the empalement. It flowers in July, and the seeds ripen in autumn.

The tenth sort grows naturally at the Cape of Good Hope; this rises with a shrubby stalk seven or eight feet high, covered with a light-coloured bark, sending out branches the whole length, which grow almost horizontally; they are garnished with roundish gray leaves which are entire, and seem torn at their base, where they are also indented. The flowers are produced in thick short spikes at the end of the branches; they are very large, and of a dark gold colour; they appear in May and June, but are not succeeded by seeds in England.

The eleventh sort grows naturally at the Cape of Good Hope; this rises with a shrubby stalk four or five feet high, dividing into branches, which are garnished with oval sawed leaves of a gray colour, and have one or two indentures at their base that seem torn. The flowers come out in whorls toward the end of the branches; they are of a fine blue colour, and larger than those of the common Sage; these appear in succession most of the summer months, and those which come early, are often succeeded by seeds which ripen in autumn.

The twelfth sort has been lately raised in the Dutch gardens, from seeds which were brought from the Cape of Good Hope. It has great resemblance to the for-

mer, but the branches are stronger and grow more erect; the leaves are longer and not so broad; their edges are not sawed; the flowers grow in long loose spikes at the end of the branches; they are larger, and of a paler blue than the other, and their empalements are broader, spread wider, and are of a pale blue colour, in which consists their difference.

All the sorts of Sage may be propagated by seeds if they can be procured; but as some of them do not perfect their seeds in England, and most of the sorts, but especially the common kinds for use, are easily propagated by slips, it is not worth while to raise them from seeds. The slips of the hardy sorts should be planted the beginning of April on a shady border, where, if they are now and then refreshed with water, if the season should prove dry, they will soon take root. When the slips have made good roots, they may be taken up with balls of earth, and transplanted where they are to remain, which should always be upon a dry soil, and where they may have the benefit of the sun: for if they are planted on a moist soil, or in a shady situation, they are very subject to be destroyed in winter; nor will these plants endure the cold so well, when planted upon a rich soil, as those which have a barren, dry, rocky soil, which is the case of most of the verticillate plants; for these will often grow upon walls, where, although they are more exposed to the cold than those plants in the ground, they are always found to remain in severe winters when the others are destroyed. The side shoots and tops of these plants may be gathered in the summer, and dried, if designed for tea, otherwise they are best taken green from the plants for most other uses. The roots of the common sorts of Sage will last several years, if they are in a dry warm soil; but where they are often cropped for use, the plants will become ragged, so there should be a succession of young ones raised every other year.

The fifth, sixth, and eighth sorts are somewhat tender, so will not live through the winter in the open air in England, therefore these must be planted into pots filled with fresh, light, sandy earth, and in winter they must be removed under a hot-bed frame, that they may have a great share of fresh air whenever the season is mild; for if they are too much drawn, they seldom flower well, and make but an indifferent appearance. In summer they must be exposed amongst other exotic plants in some well-sheltered situation, for they are pretty hardy, and only require to be sheltered from the frost. These plants must be often refreshed with water in warm weather, otherwise they will shrivel and decay; and they should be new-potted at least twice every summer, because their roots will greatly increase, which, if confined in the pots too long, will turn mouldy and decay.
